**SERIES, Trigonometrical,** are those which relate to trigonometrical lines or quantities; as

$$\sin. a + \frac{\sin. a}{2 \cdot 3 r^2} + \frac{3 \sin. a}{2 \cdot 4 \cdot 5 r^3} + \frac{3 \cdot 5 \sin. a}{2 \cdot 4 \cdot 6 \cdot 7 r^4} + \&c.$$

$$\tan. a - \frac{\tan. a}{3r} + \frac{\tan. a}{5r^3} - \frac{\tan. a}{7r^5} + \&c.$$

which are each expressions for the length of a circular arc, the former in terms of the sine, and the latter in terms of the tangent.

**SERIES, Exponential,** are those which arise from the expansion of, or whose sum depends upon exponential quantities; as

$$1 + \frac{x}{1} + \frac{x^2}{2} + \frac{x^3}{2 \cdot 3} + \frac{x^4}{2 \cdot 3 \cdot 4} + \&c.$$

which is equal to  $e$ ,  $e$  being the number whose hyperbolic logarithm is 1.

**SERIES, Recurring,** are those in which each term has a constant relation to a certain number of the preceding terms. See **RECURRING SERIES**.

**SERIES, Law of  $a$ ,** is used to denote that relation which subsists between the successive terms of a series, and by which their general term may be denoted: thus the series

$$1 + \frac{2}{3}x + \frac{8}{15}x^2 + \frac{16}{35}x^3 + \frac{128}{315}x^4 + \&c.$$

may be put under the form

$$1 + \frac{2}{3}x + \frac{2 \cdot 4}{3 \cdot 5}x^2 + \frac{2 \cdot 4 \cdot 6}{3 \cdot 5 \cdot 7}x^3 + \frac{2 \cdot 4 \cdot 6 \cdot 8}{3 \cdot 5 \cdot 7 \cdot 9}x^4 + \&c.$$

where the law by which it may be indefinitely continued is manifest; and from which we draw the general term, *viz.*

$$\frac{2 \cdot 4 \cdot 6 \dots 2(n-1)}{3 \cdot 5 \cdot 7 \dots (2n-1)} x^{n-1}.$$

**SERIES, Interpolation of.** See **INTERPOLATION**.

**SERIES, Reversion of.** See **REVERSION**.

**SERIES, Summation of,** is the finding the sum of a series, whether the number of its terms be finite or infinite; the various methods of performing which is treated of in the subsequent part of this article.

## SERIES.

*Method of series* is used in a general sense to denote the principle upon which different authors have treated this subject, as well with reference to the reversion and interpolation of series, as to the finite and approximate summation of them.

The doctrine of series is certainly one of the most important subjects of mathematical investigation, and has been very appropriately denominated by James Bernoulli the *sheet-anchor* of analysis; being our only hope and last resort, in a variety of difficult problems, which bid defiance to every other method of computation.

The summation of series, and the quadrature of a curvilinear space, are intimately connected with each other, as well in their origin as in their subsequent progress. We have stated under the article QUADRATURE, that Archimedes was the first who found the area of a curvilinear space, which he effected by means of the summation of an infinite series upon geometrical principles, and which is the first instance on record of such an operation; from which time, for nearly two thousand years, little or nothing was attempted relative to this subject; but about the middle and the latter end of the 17th century, it began to attract the general attention of mathematicians, and has since that time been pursued with a degree of perseverance and success commensurate with its great importance, and the general progress of analysis during the same period.

Wallis, in his Arithmetic of Infinites, seems to have been the first amongst the moderns who drew the attention of mathematicians to the doctrine of series. Lord Brouncker, Sir Christopher Wren, Mercator, and James Gregory, also pursued the subject with considerable success, exhibiting the quadrature and rectification of different curves under the form of infinite series.

In 1682, Leibnitz published in the Leipzig Acts a memoir entitled "De proportionibus circuli ad quadratum circumscriptum, in numeris rationalibus," in which he gave several numerical series of a very novel kind, whose sums were expressible in finite terms, without, however, accompanying them with their demonstrations; amongst the most curious of which we may reckon the following: *viz.*

$$\frac{1}{3} + \frac{1}{8} + \frac{1}{15} + \frac{1}{24} + \frac{1}{35} + \frac{1}{48} + \&c. \text{ or}$$

$$\frac{1}{2^2 - 1} + \frac{1}{3^2 - 1} + \frac{1}{4^2 - 1} + \frac{1}{5^2 - 1} + \&c.$$

The sum of an infinite number of terms of which is equal to  $\frac{3}{2}$ ; the sum of its odd terms being equal to  $\frac{1}{2}$ , and the sum of its even terms equal to  $\frac{1}{4}$ : that is

$$\frac{1}{1 \cdot 3} + \frac{1}{3 \cdot 5} + \frac{1}{5 \cdot 7} + \frac{1}{7 \cdot 9} + \frac{1}{9 \cdot 11} + \&c. = \frac{1}{2}, \text{ and}$$

$$\frac{1}{2 \cdot 4} + \frac{1}{4 \cdot 6} + \frac{1}{6 \cdot 8} + \frac{1}{8 \cdot 10} + \frac{1}{10 \cdot 12} + \&c. = \frac{1}{4}.$$

The sum of an infinite number of terms of the same series, omitting every three terms after the 1st, the 5th, the 9th, &c. as

$$\frac{1}{1 \cdot 3} + \frac{1}{5 \cdot 7} + \frac{1}{9 \cdot 11} + \frac{1}{13 \cdot 15} + \frac{1}{17 \cdot 19},$$

is equal to the area of a circle of which the inscribed square is  $\frac{1}{4}$ .

But if we begin at the second term, and thence omit every three terms, as above, we shall have

$$\frac{1}{2 \cdot 4} + \frac{1}{6 \cdot 8} + \frac{1}{10 \cdot 12} + \frac{1}{14 \cdot 16} + \&c.$$

which is equal to the area or space included between the curve and asymptote of an equilateral hyperbola, or  $\frac{1}{4}$  of the hyp. log. 2.

Leibnitz also gave in the same work for 1683, the summation of several other series of a more difficult kind, as

$$1 - \frac{1}{2 \cdot 10} + \frac{1}{2 \cdot 10^2} - \frac{1}{2 \cdot 10^3} + \frac{1}{2 \cdot 10^4} - \&c. = \frac{20}{21}$$

$$1 - \frac{2}{2 \cdot 10} + \frac{3}{2 \cdot 10^2} - \frac{4}{2 \cdot 10^3} + \frac{5}{2 \cdot 10^4} - \&c. = \left(\frac{20}{21}\right)^2$$

$$1 - \frac{3}{2 \cdot 10} + \frac{6}{2 \cdot 10^2} - \frac{10}{2 \cdot 10^3} + \frac{15}{2 \cdot 10^4} - \&c. = \left(\frac{20}{21}\right)^3$$

These, as we have before observed, were not demonstrated by Leibnitz, but this was soon after done, and many other series investigated, by the brothers John and James Bernoulli; the latter in a small tract "De Seriebus Infinitis," published with the "Ars Conjectandi;" and the former in vol. iv. of his "Opera Omnia."

From the preface to the former tract we learn, that James, having turned his attention to the doctrine of series, had discovered a few which were summable, and which he proposed to his brother; who having quickly demonstrated them, proposed others to James; this led to other propositions, and so on, till in a short time they were not only able to demonstrate all Leibnitz's series, but had discovered two general principles, which applied with great facility to a variety of new cases; the one of which was the resolution of an infinite series into an infinite number of other series; and the other, the method commonly called the summation by subtraction. We see here that spirit of emulation and rivalry with which these two brothers were constantly actuated, and to which they each probably owe many of their finest discoveries. It is only to be regretted that it terminated in a manner so unworthy of their talents and character; particularly with regard to John, who was doubtless at first much indebted to his brother's instruction, but who, notwithstanding, indulged his resentment against him for many years after his death, seeking every opportunity of aspersing his methods, and of lessening his reputation.

*The Bernoullis' Method of Series.*—The principal difference between the methods of these two celebrated mathematicians consists in this, that James, in his "Tractatus de Seriebus Infinitis," proceeds synthetically; and John, in his "Opera Omnia," analytically; but the series in both cases are nearly of the same kinds, and the summation of them depends upon the same principles; we shall, therefore, by way of illustration, abstract one or two propositions from the former work, which will be sufficient for giving the reader an idea of the spirit of the two methods above alluded to.

*Prop.*—To find the sum of an infinite number of fractions, whose denominators increase in any geometrical progression, but whose numerators proceed according to the natural numbers, or polygonal or figurate numbers, of any denomination.

*Case 1.*—When the numerators proceed according to the natural numbers, that is, when they form an arithmetical progression.

Let the proposed series, whose sum is required, be

$$\frac{a}{b} + \frac{a+c}{b \cdot d} + \frac{a+2c}{b \cdot d^2} + \frac{a+3c}{b \cdot d^3} + \&c.$$

This is obviously equal to

$$\begin{aligned} \frac{a}{1} + \frac{a}{bd} + \frac{a}{bd^2} + \frac{a}{bd^3} + \&c. &= \frac{ad}{bd-b} \\ + \frac{c}{bd} + \frac{c}{bd^2} + \frac{c}{bd^3} + \&c. &= \frac{cd}{bd-b} \\ + \frac{c}{bd^2} + \frac{c}{bd^3} + \&c. &= \frac{cd}{bd^2-bd} \\ + \frac{c}{bd^3} + \&c. &= \frac{cd}{bd-bd^2} \\ + \&c. &= \&c. \end{aligned}$$

Each of which series being geometrical, are found by the known rule, for such progressions; and it is obvious that all these sums, except the first, are also in geometrical progression; the sum of which, *viz.* of

$$\begin{aligned} \frac{cd}{bd-b} + \frac{cd}{bd-bd} + \frac{cd}{bd^2-bd^2} + \frac{cd}{bd^3-bd^3} \\ + \&c. = \frac{cd}{b(d-1)^2} \end{aligned}$$

to which therefore adding  $\frac{ad}{b(d-1)}$ , we have  $\frac{ad}{b(d-1)}$

+  $\frac{cd}{b(d-1)^2}$  for the sum of the proposed series.

*Case 2.*—When the numerators of the fractions proceed according to the triangular numbers. Let

$$\frac{c}{b} + \frac{3c}{bd} + \frac{6c}{bd^2} + \frac{10c}{bd^3} + \&c.$$

be the proposed series. This may be resolved as follows: *viz.*

$$\begin{aligned} \frac{c}{b} + \frac{c}{bd} + \frac{c}{bd^2} + \frac{c}{bd^3} + \&c. &= \frac{cd}{bd-b} \\ + \frac{2c}{bd} + \frac{2c}{bd^2} + \frac{2c}{bd^3} + \&c. &= \frac{2c}{bd-b} \\ + \frac{3c}{bd^2} + \frac{3c}{bd^3} + \&c. &= \frac{3c}{bd^2-bd} \\ + \frac{4c}{bd^3} + \&c. &= \frac{4c}{bd^3-bd^2} \\ + \&c. &= \&c. \end{aligned}$$

which sums, with the exception of the first, constitute a series agreeing in form with that solved above, and from

which we derive  $\frac{cd}{b(d-1)^2}$  for the sum required.

*Cor.*—If we make  $a$  in the first series = 0, the sum of that series will be to the sum of the latter, as  $d-1 : d$ ; that is,

as  $d-1 : d^2 :: \frac{cd}{b(d-1)^2} : \frac{cd^3}{b(d-1)^3}$ . And when the

numerators proceed according to the figurate numbers of the first order, *viz.* 1, 4, 20, 35, then the sum of this series will be to that of the latter, as  $d : d-1$ ; that is,

as  $d-1 : d :: \frac{cd^3}{b(d-1)^3} : \frac{cd^3}{b(d-1)^4}$  = the sum of the

series  $\frac{c}{b} + \frac{4c}{bd} + \frac{10c}{bd^2} + \frac{20c}{bd^3} + \frac{35c}{bd^4} + \&c.$

In a similar manner is found the sum of the series, when the numerators are squares, cubes, &c. from which the author draws the following results; *viz.*

Nat. Num.	$\frac{1}{2} + \frac{2}{2^2} + \frac{3}{2^3} + \frac{4}{2^4} + \&c. = 2$
Trian. Num.	$\frac{1}{2} + \frac{3}{2^2} + \frac{6}{2^3} + \frac{10}{2^4} + \&c. = 4$
Fig. 1st order	$\frac{1}{2} + \frac{4}{2^2} + \frac{10}{2^3} + \frac{20}{2^4} + \&c. = 8$
Squares	$\frac{1}{2} + \frac{4}{2^2} + \frac{9}{2^3} + \frac{16}{2^4} + \&c. = 6$
Cubes	$\frac{1}{2} + \frac{8}{2^2} + \frac{27}{2^3} + \frac{64}{2^4} + \&c. = 26$

As an illustration of the second method, that is, of summation by subtraction, we shall give an abstract of James Bernoulli's fifteenth proposition, which is as follows.

*Prop.*—To find the sum of an infinite series of fractions, whose numerators constitute a series of equal numbers, and denominators, a series of triangular numbers, or of their multiples.

From the series  $\frac{a}{c} + \frac{a}{2c} + \frac{a}{3c} + \frac{a}{4c} + \frac{a}{5c} = S$

subtract  $\frac{a}{2c} + \frac{a}{3c} + \frac{a}{4c} + \frac{a}{5c} + \frac{a}{6c} = S - \frac{a}{c}$

we have  $\frac{a}{2c} + \frac{a}{6c} + \frac{a}{12c} + \frac{a}{20c} + \frac{a}{30c} = \frac{a}{c}$

the double of which =  $\frac{a}{c} + \frac{a}{3c} + \frac{a}{6c} + \frac{a}{10c} + \frac{a}{15c} = \frac{2a}{c}$

which last is a series of fractions of the form proposed, their denominators forming the series of triangular numbers, multiplied by the constant quantity  $c$ . Thus in numbers; if from the series

$$1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} - \&c. = S$$

(without regarding what may be the value of  $S$ ), we take

$$\frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5} + \frac{1}{6} - \&c. = S - 1$$

we shall have

$$\frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \&c. = 1.$$

In the same way we find

$$\frac{1}{1 \cdot 3} + \frac{1}{2 \cdot 4} + \frac{1}{3 \cdot 5} + \frac{1}{4 \cdot 6} + \&c. = \frac{3}{4}.$$

On the same principle, John Bernoulli demonstrated, that the sum of the reciprocals of the natural numbers is infinite. Let

$$\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \&c.$$

be changed into the equivalent form

$$\frac{1}{2} + \frac{2}{6} + \frac{3}{12} + \frac{4}{20} + \frac{5}{30} + \&c.$$

## SERIES.

From this general formula are readily drawn the following particular expressions for the sums of the different orders of polygonal and figurate numbers; as also for the squares, cubes, and higher powers.

### Figurate Numbers.

Series.	General term.	Sum of $n$ terms.
$1 + 2 + 3 + 4 + \dots$	$n$	$\frac{n(n+1)}{1 \cdot 2}$
$1 + 3 + 6 + 10 + \dots$	$\frac{n(n+1)}{1 \cdot 2}$	$\frac{n(n+1)(n+2)}{1 \cdot 2 \cdot 3}$
$1 + 4 + 10 + 20 + \dots$	$\frac{n(n+1)(n+2)}{1 \cdot 2 \cdot 3}$	$\frac{n(n+1)(n+2)}{1 \cdot 2 \cdot 3}$
$1 + 5 + 15 + 35 + \dots$	&c.	&c.

where the law of continuation is sufficiently obvious.

### Polygonal Numbers.

Series.	General term.	Sum of $n$ terms.
$1 + 2 + 3 + 4 + \dots$	$n$	$n + \frac{n(n-1)}{1 \cdot 2}$
$1 + 3 + 6 + 10 + \dots$	$\frac{n^2 + n}{1 \cdot 2}$	$n + \frac{2n(n-1)}{1 \cdot 2} + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3}$
$1 + 4 + 9 + 16 + \dots$	$\frac{2n^2 - n}{1 \cdot 2}$	$n + \frac{3n(n-1)}{1 \cdot 2} + \frac{2n(n-1)(n-2)}{1 \cdot 2 \cdot 3}$
$1 + 5 + 12 + 22 + \dots$	$\frac{3n^2 - n}{1 \cdot 2}$	$n + \frac{4n(n-1)}{1 \cdot 2} + \frac{3n(n-1)(n-2)}{1 \cdot 2 \cdot 3}$

universally; the general term being

$$\frac{(m-2)n^2 - (m-4)n}{1 \cdot 2}$$

The sum of  $n$  terms =  $n + \frac{(m-1)n(n-1)}{1 \cdot 2} + \frac{(m-2)n(n-1)(n-2)}{1 \cdot 2 \cdot 3}$ .

### Powers.

Series.	General term.	Sum.
$1^2 + 2^2 + 3^2 + 4^2 + \dots$	$n^2$	$\frac{n^3}{3} + \frac{n^2}{2} + \frac{n}{6}$
$1^3 + 2^3 + 3^3 + 4^3 + \dots$	$n^3$	$\frac{n^4}{4} + \frac{n^3}{2} + \frac{n^2}{4}$
$1^4 + 2^4 + 3^4 + 4^4 + \dots$	$n^4$	$\frac{n^5}{5} + \frac{n^4}{2} + \frac{n^3}{3} - \frac{n}{30}$
$1^5 + 2^5 + 3^5 + 4^5 + \dots$	$n^5$	$\frac{n^6}{6} + \frac{n^5}{2} + \frac{5n^4}{12} - \frac{n^2}{12}$
&c.      &c.	&c.	&c.

A variety of other series fall under the above general formula of M. Montmort; viz. series of which the sum may be exhibited in a finite form: and in all cases where the successive differences decrease, an approximation may be obtained by it, and that with a considerable degree of facility, when the terms are alternately + and - 1, but when they are all plus, or all minus, except the first, little, if any, advantage is gained by it.

The above method of summation is commonly called the *differential method*, and was first used for interpolation by Briggs, in the construction of his table of logarithms. Newton also applied it to a variety of interesting problems in his "Methodus Differentialis;" but Montmort, as far as we have been able to trace, was the first who employed it in the summation of series.

The following formulæ, all relating to the differential method, will not be unacceptable to the reader.

Let  $a + b + c + d + e + f + \dots$  be any series; make

$$D' = b - a$$

$$D'' = a - 2b + c$$

$$D''' = a - 3b + 3c - d$$

$$D^{(4)} = a - 4b + 6c - 4d + e$$

$$\dots \dots \dots$$

$$D^{(n)} = a - nb + \frac{n(n-1)}{1 \cdot 2} c - \frac{(n-1)(n-2)}{1 \cdot 2 \cdot 3} d + \dots$$

From which last general formula the first term of any order of differences may be found independent of all those which precede it.

Again,

## SERIES.

Again, let  $N$  represent the  $n$ th term, and  $S$  the sum of  $n$  terms; then will

$$N = a + \frac{(n-1)}{1} D' + \frac{(n-1)(n-2)}{1 \cdot 2} D'' + \frac{(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3} D''' + \&c.$$

$$S = na + \frac{n(n-1)}{1 \cdot 2} D' + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} D'' + \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} D''' + \&c.$$

which latter expression for the sum is, as we have above observed, due to M. Montmort. The same author also published in the *Philosophical Transactions* for 1718, some other formulæ for the summation of series; but as these are nothing more than particular cases of the method of increments, we shall not notice them in this place; but refer the reader to the article *INCREMENTS*, for an illustration of the method of summation as depending upon those principles, first published by Dr. Brooke Taylor, in his "*Methodus Incrementorum*," 1715.

4. *De Moivre's Method of Series.* The next author who made any considerable improvement in this theory was De Moivre, to whom we owe the doctrine of *RECURRING SERIES*, on the principles of which we have spoken at some length under that article of the present work; we shall not therefore enter again upon the subject in this place, but confine ourselves to an illustration of his method for finding summable series, which is not referred to in the article above mentioned; it was first given by him in his "*Miscellanea Analytica*," 1730.

Let there be assumed any series, and let this be multiplied by any binomial or trinomial factor, such that the resulting series shall have its powers of  $x$  recurring again in the same order; then, by equating the resulting series to 0, and transposing the negative terms, a new numerical series will arise, the sum of which will be given.

Thus, let there be taken the series

$$1 + \frac{1}{2}x + \frac{1}{3}x^2 + \frac{1}{4}x^3 + \frac{1}{5}x^4 + \&c. = S.$$

Multiplying this by  $x - 1$ , we have

$$-1 + \frac{1}{1 \cdot 2}x + \frac{1}{2 \cdot 3}x^2 + \frac{1}{3 \cdot 4}x^3 + \&c. = (x-1)S.$$

Whence, making  $x - 1 = 0$ , or  $x = 1$ , we have

$$\frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \&c. = 1.$$

Again, assume

$$1 + \frac{1}{2}x + \frac{1}{3}x^2 + \frac{1}{4}x^3 + \&c. = S.$$

Multiplying by  $x^2 - 1$ , we have

$$-1 - \frac{1}{2}x + \frac{2}{1 \cdot 3}x^2 + \frac{2}{2 \cdot 4}x^3 + \frac{2}{3 \cdot 5}x^4 + \&c. = (x^2-1)S$$

where making again  $x = 1$ , we have

$$\frac{2}{1 \cdot 3} + \frac{2}{2 \cdot 4} + \frac{2}{3 \cdot 5} + \frac{2}{4 \cdot 6} + \frac{2}{5 \cdot 7} + \&c. = \frac{3}{2}, \text{ or}$$

$$\frac{1}{1 \cdot 3} + \frac{1}{2 \cdot 4} + \frac{1}{3 \cdot 5} + \frac{1}{4 \cdot 6} + \frac{1}{5 \cdot 7} + \&c. = \frac{3}{4}.$$

As another example, let the same series

$$1 + \frac{1}{2}x + \frac{1}{3}x^2 + \frac{1}{4}x^3 + \frac{1}{5}x^4 + \&c. = S$$

be multiplied by

$$(2x-1)(3x-1) = 6x^2 - 5x + 1,$$

and we have

$$1 - \frac{9}{1 \cdot 2}x + \frac{23}{1 \cdot 2 \cdot 3}x^2 + \frac{38}{2 \cdot 3 \cdot 4}x^3 + \frac{57}{3 \cdot 4 \cdot 5}x^4 + \&c.$$

$$= (2x-1)(3x-1)S;$$

where, by making  $x = \frac{1}{2}$ , and  $x = \frac{1}{3}$ , we have the two following series:

$$1. \frac{23}{1 \cdot 2 \cdot 3} \cdot \frac{1}{4} + \frac{38}{2 \cdot 3 \cdot 4} \cdot \frac{1}{8} + \frac{57}{3 \cdot 4 \cdot 5} \cdot \frac{1}{16} + \&c. = \frac{5}{4}$$

$$2. \frac{23}{1 \cdot 2 \cdot 3} \cdot \frac{1}{9} + \frac{38}{2 \cdot 3 \cdot 4} \cdot \frac{1}{27} + \frac{57}{3 \cdot 4 \cdot 5} \cdot \frac{1}{81} + \&c. = \frac{1}{2}$$

The law of both which series is obvious, the numerators being in arithmetical progression. This method is not much different in principle from the second method of Bernoulli above explained.

5. *Stirling's Method of Series.* In the recurring series of De Moivre, each term is connected with a certain number of the preceding terms, by a constant and invariable law, but in the series considered by Stirling, in his "*Methodus Differentialis*," 1730, each term is a certain function of the number of terms from the beginning, or from some determinate term of the series; which function may therefore be considered as the general term, and the method of summation depends on the following principles.

Having first determined the general term of the series in some function of  $x$ , its distance from the beginning, or some determinate term of the series; it follows, that the sum of all the terms to that place will also be some function of  $x$ . Therefore, if  $x'$  is made to denote the distance of any other term from the same point, the sum to that term will be the same function of  $x'$ , as the other sum is of  $x$ ; and each term of the series may be considered to represent the difference between two consecutive sums, or the difference between two similar functions, *viz.* of  $x-1$  and  $x$ ; and the object of the author is to determine what those sums or functions are from the difference between them being given.

To be a little more explicit, if there be any series of quantities

$$a, b, c, d, \dots, l', t', \&c.$$

proceeding from the first  $a$ , by any uniform law, either increasing or decreasing; and if  $x$  be taken to represent the distance of any term, as  $t$ , from the beginning of the series, or from any term in the same, then will  $t$  be expressible by some function of  $x$ ;  $t'$  by the same function of  $x+1$ ;  $t''$  by the same function of  $x+2$ , &c.: denoting therefore this function by  $f(x)$ , we shall have

$$t = f(x-1), t' = f(x), t'' = f(x+1), \&c.$$

Also if  $f^0, f, f', f'', \&c.$  denote the sums of all the terms from the beginning to the terms  $t, t', t'', \&c.$  respectively, these several sums will also be some function of  $x-1, x, x+1, x+2, \&c.$  which we may denote by

$$f^0 = \varphi(x-1), f = \varphi(x), f' = \varphi(x+1):$$

whence we draw immediately

$$f - f^0 = t, \text{ or } \varphi(x) - \varphi(x-1) = f(x).$$

Now

# SERIES.

Now the function  $f(x)$  is given, being the general term of the series, and the object of enquiry is, from this given function to determine the two functions  $\phi(x)$  and  $\phi(x-1)$ , of which it is the difference; for the former of these,  $\phi(x)$ , will then be the sum of the series to the term  $x$  inclusive.

To illustrate this by a familiar example; let the proposed series be

$$1 + 3 + 5 + 7 + 9, \&c.$$

the general term of which is  $2x - 1$ ; therefore,

$$\phi(x) - \phi(x-1) = 2x - 1;$$

whence we have obviously  $\phi(x) = x^2$ , for

$$x^2 - (x-1)^2 = 2x - 1;$$

therefore  $x^2$  is the sum of  $x$  terms of the above series.

Again, let it be required to find the sum of  $x$  terms of the series

$$1, 7, 19, 37, \&c.$$

of which the general term

$$f(x) = 3x^2 - 3x + 1,$$

therefore,

$$2x - \phi(x-1) = 3x^2 - 3x + 1;$$

consequently  $\phi(x) = x^3$ , the sum of  $x$  terms of the series.

In these two examples, the finding the sum  $\phi(x)$  from the difference is extremely simple; but in the generality of cases it is far from being so obvious, and even in some, it is impossible to exhibit the sum of the series in any other manner than by another series; but as in the latter case the transformed series may be made to possess almost any degree of convergency we please, this method of summation is still attended with important advantages, and even more perhaps in the latter case, than in any other; because most, if not all, summable series, may be summed on some other principles; *viz.* either by the method of *recurring series*, or by the *differential method*, or by *increments*; while the transformation of a slowly converging series, into another of rapid convergency, is frequently extremely difficult to effect on any other principle than that of Stirling's, or some other tantamount to it.

From what is stated above it appears, that the principal object of enquiry is, in what manner we are to determine a function from the difference between two states of it being given. In the examples we have chosen for illustration, the function whence the difference is derived is extremely obvious; but this in many cases is, as we have before observed, attended with some difficulty. In this respect the summation of series resembles in a great degree the inverse method of fluxions. There is little or no difficulty in any case in finding the fluxions of any proposed quantity; but the finding of a fluent of any given fluxion is far from possessing the same facility. So also in the present case, if the question was to find the difference between two different states of a given function, we should find the operation direct and simple; but the converse, or the finding the function from the difference being known, is indirect, and frequently difficult to be determined.

It is obvious also, that two different functions, which differ from each other only by some constant quantity, will give the same difference, and, consequently, a given difference may give rise to different functions, the same as happen in finding fluents, and it will therefore be necessary in this case, as in that, to have recourse to a *correction*, which will be found in the same manner as is practised in that calculus,

*viz.* by finding the value of the series, when the variable quantity is made equal to zero, or some determined magnitude.

*Of the general Term of a Series.*—With regard to the general term of a series, it is difficult, particularly within our limits, to lay down any fixed or constant rule for its determination; it is besides seldom necessary, as the law of the series is commonly presented in the *terms of the series itself*; we shall leave this determination, therefore, as in fact it must be in most cases, to the ingenuity of the analyst, and shall proceed immediately to the other subjects of investigation.

It may not, however, be amiss to state; that in such series as have any order of their differences vanish, the general term is always of the form

$$A n^m + B n^{m-1} + C n^{m-2} + D n^{m-3} + \&c.$$

where  $m$  denotes the order of the differences that vanish, and  $n$  the number of terms from the beginning. The values of  $A, B, C, D, \&c.$  being found by making  $n$  successively equal to 1, 2, 3, &c., and equating the results with the 1st, 2d, 3d, &c. terms of the series.

*Of the Transformation of a given Function to an equivalent one of a different Form.*—Since we shall confine our investigation only to those series whose terms are either integers or rational fractions, it is obvious that the general term must also be some rational function either of the form,

$$a + bx + cx^2 + dx^3 + \&c. \text{ or}$$

$$\frac{a + bx + cx^2 + dx^3 + \&c.}{a' + b'x + c'x^2 + d'x^3 + \&c.}$$

and our object is to transform either of those general forms into others, whence the general function from which they have been derived may be the more readily determined. Different transformations may be employed for this purpose; but the most general, and that, in fact, to which Stirling principally confines himself, is to transform the above general terms into other equivalent ones of the form

$$A + Bx + Cx(x-1) + Dx(x-1)(x-2) + \&c. \text{ or}$$

$$\frac{A}{x(x+1)} + \frac{B}{x(x+1)(x+2)} + \frac{C}{x(x+1)(x+2)(x+3)}$$

from either of which the general function whence they have been derived may be readily determined. For it is obvious that the first is equal to the difference between the two similar functions

$$Ax + \frac{1}{2}B(x+1)x + \frac{1}{6}C(x+1)x(x-1) + \frac{1}{24}D(x+1)x(x-1)(x-2) + \&c.$$

and

$$A(x-1) + \frac{1}{2}Bx(x-1) + \frac{1}{6}Cx(x-1)(x-2) + \frac{1}{24}Dx(x-1)(x-2)(x-3) + \&c.$$

For by subtracting these one from the other, we have

$$A + Bx + Cx(x-1) + Dx(x-1)(x-2) + \&c.$$

And therefore, from what has been stated, the first of the above formulae will be the general sum of that series of which the general term is

$$A + Bx + Cx(x-1) + Dx(x-1)(x-2) + \&c.$$

And in a similar manner it may be shewn, that the second general form is equal to the difference between the two similar functions

SERIES.

$$\frac{A}{x} + \frac{B}{2x(x+1)} + \frac{C}{3x(x+1)(x+2)} + \frac{D}{4x(x+1)(x+2)(x+3)} + \&c.$$

and

$$\frac{A}{1+x} + \frac{B}{2(x+1)(x+2)} + \frac{C}{3(x+1)(x+2)(x+3)} + \frac{D}{4(x+1)\dots(x+4)} + \&c.$$

For by subtracting these one from the other, we have

$$\frac{A}{x(x+1)} + \frac{B}{x(x+1)(x+2)} + \frac{C}{x(x+1)(x+2)(x+3)} + \&c.$$

and consequently the former is the sum of that series whose general term is

$$\frac{A}{x(x+1)} + \frac{B}{x(x+1)(x+2)} + \frac{C}{x(x+1)(x+2)(x+3)} + \&c.$$

So that the whole difficulty is now reduced to that of transforming any proposed function, expressing the general term of a series into an equivalent function of one or other of the above forms.

To transform a quantity of the form

$$a + bx + cx^2 + dx^3 + ex^4 + \&c.$$

into another of the form

$$A + Bx + Cx(x-1) + Dx(x-1)(x-2) + \&c.$$

By the actual multiplication of the latter formula, we have

$$\begin{aligned} A &= A \\ Bx &= Bx \\ Cx(x-1) &= -Cx + Cx^2 \\ Dx(x-1)(x-2) &= Dx - 3Dx^2 + Dx^3 \end{aligned}$$

And equating the co-efficients of the like powers of  $x$  in this and the original series, we obtain

$$\left. \begin{aligned} d &= D \\ c &= C - 3D \\ b &= B - C + D \\ a &= A \end{aligned} \right\} \text{or} \left\{ \begin{aligned} D &= d \\ C &= c + 3d \\ B &= b + c + 2d \\ A &= a \end{aligned} \right.$$

Whence the values of  $A, B, C, D, \&c.$  are determined by means of the known co-efficient,  $a, b, c, d, \&c.$  And the same method may obviously be employed in any other similar case. The following tablet, however, will facilitate the operation; *viz.*

$$\begin{aligned} x &= x \\ x^2 &= x + x(x-1) \end{aligned}$$

Now

$$\frac{1}{x^2} = \frac{1}{x(x+1)} + \frac{1}{x(x+1)(x+2)} + \frac{1}{x(x+1)(x+2)(x+3)} + \frac{6}{x(x+1)\dots(x+4)} + \&c.$$

$$\frac{1}{x^3} = \frac{1}{x(x+1)(x+2)} + \frac{3}{x(x+1)(x+2)(x+3)} + \frac{11}{x(x+1)\dots(x+4)} + \&c.$$

$$\frac{1}{x^4} = \frac{1}{x(x+1)(x+2)(x+3)} + \&c. \&c.$$

Or by making

$$\begin{aligned} A &= \dots \\ B &= \dots + \gamma \\ C &= 2\delta + \dots - 3\delta + \dots \\ D &= 6\epsilon + 11\delta + \dots - 6\epsilon + \dots \\ E &= 24\zeta + 5\eta + \dots - 35\zeta + 10\eta + \dots \\ F &= 120\zeta + 274\eta + 225\theta + 85\delta + 15\epsilon + \dots \end{aligned}$$

$$\begin{aligned} x &= x + 3x(x-1) + x(x-1)(x-2) \\ x^2 &= x + 7x(x-1) + 6x(x-1)(x-2) + x(x-1)(x-2)(x-3) \\ \&c. &= \&c. \end{aligned}$$

As an example, let

$$1 + 3x + 4x^2$$

be the proposed general term. Here

$$\begin{aligned} 3x &= 3x \\ 4x^2 &= 4x + 4x(x-1) \end{aligned}$$

therefore,

$$1 + 3x + 4x^2 = 1 + 7x + 4x(x-1)$$

which latter is of the form required.

To transform any general term of the form

$$\frac{a + bx + cx^2 + dx^3 + \&c.}{a' + b'x + c'x^2 + d'x^3 + \&c.}$$

into another of the form

$$\frac{A}{x(x+1)} + \frac{B}{x(x+1)(x+2)} + \frac{C}{x(x+1)(x+2)(x+3)} + \&c.$$

The most general method of performing this transformation is, by actual division to reduce it first to the form

$$\frac{\alpha}{x^2} + \frac{\beta}{x^3} + \frac{\gamma}{x^4} + \frac{\delta}{x^5} + \&c.$$

## SERIES.

which values substituted for A, B, C, &c. will give the transformation sought, and which will terminate by one of those expressions becoming zero, when the series is summable, but when it is not the expression itself will become an infinite series, but such that we may give to it almost any degree of convergency at pleasure.

Let us now illustrate what has been said by a few examples, remembering that the sum of a series, whose general term is

$$A + Bx + Cx(x-1) + Dx(x-1)(x-2), =$$

$$Ax + \frac{1}{2}B(x+1)x + \frac{1}{3}C(x+1)x(x-1) + \&c.$$

Let it be proposed to sum the series of odd numbers,

$$1 + 3 + 5 + 7 + \&c.$$

Here the general term is  $2x - 1$ , or  $-1 + 2x$ ; so that  $a = -1$  and  $b = 2$ : whence  $A = -1$ , and  $B = 2$ , and  $C = 0$ ; whence  $Ax + \frac{1}{2}B(x+1)x = -x + x^2 - x = x^2$ , which is the known expression for the sum of  $x$  terms of the above series.

Again, require the sum of the series,

$$1 \cdot 2 + 2 \cdot 3 + 3 \cdot 4 + 4 \cdot 5 + \&c.$$

Here the general term is  $x(x+1)$ , or  $x^2 + x$ : by the preceding tablet,

$$\left. \begin{aligned} x &= x \\ x^2 &= x + x(x-1) \end{aligned} \right\} = 2x + x(x-1).$$

Therefore  $A = 0$ ,  $B = 2$ , and  $C = 1$ ; whence we have

$$\frac{1}{2}B(x+1)x + \frac{1}{3}C(x+1)x(x-1) =$$

$$(x+1)x + \frac{1}{3}(x+1)x(x-1) =$$

$$\frac{1}{3}(x^3 + 3x^2 + 2x), \text{ the sum of } x \text{ terms, as required.}$$

But as there is no advantage gained by the application of this method to series of the above kind, nor indeed to any summable series, as these are commonly more readily resolved by some one of the preceding methods than by this, we shall pass immediately to series of the second kind, in which it possesses a facility of application, which is perhaps unattainable by any other principle at present known.

Here we must observe, that after the general term of any series is reduced to the form,

$$\frac{A}{x(x+1)} + \frac{B}{x(x+1)(x+2)} + \frac{C}{x(x+1)(x+2)(x+3)} + \&c.$$

the sum of that series is expressed by

$$\frac{A}{x} + \frac{B}{2x(x+1)} + \frac{C}{3x(x+1)(x+2)} + \&c.$$

$$\frac{1}{4x(x+1)} + \frac{1}{8x(x+1)(x+2)} + \frac{1 \cdot 3}{16x(x+1)(x+2)(x+3)} + \frac{1 \cdot 3 \cdot 5}{32x(x+1)(x+2)(x+3)(x+4)} + \&c.;$$

where the law of continuation is obvious, and the sum will be expressed by

$$\frac{1}{4x} + \frac{1}{16x(x+1)} + \frac{1 \cdot 3}{48x(x+1)(x+2)} + \frac{1 \cdot 3 \cdot 5}{128x(x+1)(x+2)(x+3)} + \&c.;$$

in which the law is also obvious, the co-efficients in the denominator being  $4 = 2^2$ ,  $16 = 2^4 \times 2$ ,  $48 = 2 \times 3$ ,  $128 = 2^7 \times 4$ , &c.; but the series will not terminate, because the original general term  $\frac{1}{4x(x+\frac{1}{2})}$  includes the fraction  $\frac{1}{2}$ .

1. Let it be proposed to find the sum of the infinite series,

$$\frac{1}{1 \cdot 4 \cdot 7} + \frac{1}{4 \cdot 7 \cdot 10} + \frac{1}{7 \cdot 10 \cdot 13} + \&c.$$

where the general term is

$$\frac{1}{3x(3x+3)(3x+6)} = \frac{1}{27x(x+1)(x+2)};$$

$x$  being successively  $\frac{1}{3}$ ,  $1\frac{1}{3}$ ,  $2\frac{2}{3}$ , &c.

Now this is of the required form,  $A$  being  $= 0$ , and

$$B = \frac{1}{27}; \text{ therefore the required sum is } \frac{1}{54x(x+1)} = \frac{1}{24}$$

by taking  $x = \frac{1}{3}$ , its first value. If we took  $x = 1\frac{1}{3}$ ,

we should have the sum of all the terms of the series, except the first; if  $x = 2\frac{2}{3}$ , we should have the sum of all but the two first terms, and so on: and it is by this means that we are enabled to give so great a degree of convergency in those series that are not summable; for we may assume any one of the values of  $x$ , and by that means give almost any magnitude to the denominators of our converging fractions; observing only, that such of the leading terms of the series as are not included must be summed by themselves, and added to the approximation found as above. As this is the great characteristic of Stirling's method, we shall confine our future remarks to one or two examples, which are not summable, in order to illustrate the nature of his approximations.

Let there be proposed the series,

$$\frac{1}{1 \cdot 2} + \frac{1}{3 \cdot 4} + \frac{1}{5 \cdot 6} + \frac{1}{7 \cdot 8} + \&c.;$$

which is that found by lord Brounker, for the quadrature of the hyperbola.

Here the general term is

$$\frac{1}{2x(2x+1)}, \text{ or } \frac{1}{4x(x+\frac{1}{2})} = \frac{1}{4x^2+2x};$$

taking  $x = \frac{1}{2}$ ,  $1\frac{1}{2}$ ,  $2\frac{1}{2}$ , &c. Now

$$\frac{1}{4x^2+2x} = \frac{1}{4x^2} - \frac{1}{8x^3} + \frac{3}{16x^4} - \frac{1 \cdot 3 \cdot 5}{32x^5} + \&c.;$$

that is,

$$A = \frac{1}{4}, B = \frac{1}{8}, C = \frac{3}{16}, D = \frac{-1 \cdot 3 \cdot 5}{32}, \&c.;$$

whence  $\frac{1}{4x^2+2x}$ , when converted into the required form, is,

The original series has, therefore, been converted into another infinite series, but with this advantage attending the latter, that we may give it almost any degree of convergency at pleasure, according to the value we give to  $x$ . If we assume  $x = 13\frac{1}{2}$ , which is its value in the 14th term, then the preceding series will exhibit the sum of the original series

## SERIES.

series from that term, to which adding the sum of the first 13 terms, we have, for the whole sum,

13 first terms	-	-	= .674285961
9 first terms of the new series			= .0188861219
			= .693147180
Whole sum			= .693147180

This is true to nine places of decimals, which, if we had used the original series, would have required the summation of at least *one hundred million* of its terms.

Hence the advantage of this transformation, which con-

Now, from what has been said, it appears that

$$\frac{1}{x} = \frac{1}{x(x+1)} + \frac{1}{x(x+1)(x+2)} + \frac{1 \cdot 2}{x(x+1)(x+2)(x+3)} + \frac{1 \cdot 2 \cdot 3}{x(x+1)(x+2)(x+3)(x+4)} + \&c.;$$

and consequently the sum will be

$$\frac{1}{x} + \frac{1}{2x(x+1)} + \frac{1 \cdot 2}{3x(x+1)(x+2)} + \frac{1 \cdot 2 \cdot 3}{4x(x+1)(x+2)(x+3)} + \&c.;$$

in which substituting 13 for  $x$ , viz. its 13th value, we find, by summing 13 terms of the new series, and adding that sum = .079957427, to the sum of the first 12 terms of the original series, viz. 1.564976638, we have 1.644934065 for the whole approximate sum, true to nine places of decimals.

Our limits will not allow of our entering farther upon this method, and we shall therefore conclude our illustration of it, by merely giving the author's formula for the summation of those series, in which the successive powers of an

$$x^{z+n} \times \left\{ \frac{a}{(1-x)z} + \frac{b-Ax}{(1-x)z(z+1)} + \frac{c-2Bx}{(1-x)z(z+1)(z+2)} + \frac{d-3Cx}{(1-x)z(z+1)(z+2)(z+3)} + \&c. \right\};$$

where A, B, C, &c. represent the terms immediately preceding those in which they are found.

This latter expression, like those in the preceding propositions, will terminate when the series is summable: in other cases, it will be itself an infinite series, but such that we may give to it any degree of convergency required.

*Simpson's Method of Series.*—In 1743 Simpson published his "Mathematical Dissertations on a variety of Physical and Analytical Subjects," and amongst other interesting researches in that work, there is one relating to the summation of series, which is perhaps as general and complete as any we have yet noticed; at least, if we except (with regard to approximations) that of Stirling's, above explained. This method consists in deriving the sum of one series from that of another being given or known; which former sum is expressed by a finite or infinite formula, according as the successive differences of certain parts of its terms are of definite or indefinite extent; thus, if

$$a^n + b a^{n-1} x + c a^{n-2} x^2 + d a^{n-3} x^3 + \&c.$$

be any power ( $n$ ) of the binomial  $a+x$ ,  $n$  being either integral, fractional, positive, or negative; and the terms of it be respectively multiplied by any series of quantities,  $p, q, r, s, \&c.$ ; and we make  $q-p = D'$ ,  $r-2q+p = D''$ , &c. viz.  $D', D'', D'''$ , &c. being the first terms of the successive orders of differences, then will the sum of

$$a^n p + b a^{n-1} x \cdot q + c a^{n-2} x^2 \cdot r + d a^{n-3} x^3 \cdot s + \&c.$$

be expressed by

$$p(a+x)^n + D' b x (a+x)^{n-1} + D'' c x^2 (a+x)^{n-2} + D''' d x^3 (a+x)^{n-3} + \&c.;$$

which formula will obviously be finite, if any order of the

fits in our being able, by the summation of a few of the leading terms of the original series, to give any degree of convergency to our transformed series, and thereby to perform the same upon a few terms, as would require the labour of ages to effect upon the series in its original form.

As another example, let the series,

$$\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \&c.$$

be proposed, in which the general term is  $\frac{1}{x^2}$ .

indeterminate quantity enter; all those which we have at present considered, having been wholly numerical. The formula for this purpose is as follows.

If the terms of any series be formed by writing any number, differing by unity, for  $z$  in the quantity,

$$x^{z+n} \times \left\{ \frac{a}{z} + \frac{b}{z(z+1)} + \frac{c}{z(z+1)(z+2)} + \&c. \right\};$$

then the sum will be expressed by

differences,  $D', D'', D'''$ , &c. become zero; but, in other cases, the new series will also be infinite, the same as that from which it is derived.

By giving to  $a, x$ , and  $n$  different values, and to the series  $p, q, r, s, \&c.$  different laws, a great variety of particular cases may be deduced, which our limits, however, will not admit of detailing.

Again, representing  $(a+x)^n$ , as before, by

$$a^n + b a^{n-1} x + c a^{n-2} x^2 + d a^{n-3} x^3 + \&c.$$

if  $r$  be any positive number, and we make  $S = (a+x)^{n+r}$  minus its first  $r$  terms, then will the sum of the series

$$\frac{a^n}{1 \cdot 2 \cdot 3 \cdot \dots \cdot r} + \frac{b a^{n-1} x}{2 \cdot 3 \cdot 4 \cdot \dots \cdot (r+1)} + \frac{c a^{n-2} x^2}{3 \cdot 4 \cdot 5 \cdot \dots \cdot (r+2)} + \&c.$$

whether finite or infinite, be expressed by

$$\frac{S}{(n+1)(n+2)(n+3) \cdot \dots \cdot (n+r) r'}$$

From which general formula a great variety of particular cases may be drawn, according to the different values that are given to  $a, x$ , and  $n$ .

Again, let the sum of the series

$$a x^p + b x^{p+n} + c x^{p+2n} + d x^{p+3n} + \&c. = A$$

and the terms be respectively multiplied by the terms of the arithmetical progression  $r, r+n, r+2n$ , then will the sum of the series thence arising (B), viz.

$$r a x^p + (r+n) b x^{p+n} + (r+2n) c x^{p+2n} + \&c.$$

be expressed by the fluxional formula

$$(r - p) A + \frac{x \dot{A}}{x} = B;$$

where, because it is given in finite terms,  $\dot{A}$  will always likewise be had in finite terms, and consequently, also, the value of  $B$ . And in the same manner as we have

$$a x^p + b x^{p+n} + c x^{p+2n} + \&c. = A$$

$$r a x^p + (r + n) b x^{p+n} + (r + 2n) c x^{p+2n} + \&c. =$$

$$(r - p) A + \frac{x \dot{A}}{x} = B;$$

so also

$$r s a x + (r + n) (s + n) b x^{p+n} + (r + 2n) (s + 2n) c x^{p+2n} + \&c. =$$

$$(s - p) B + \frac{x \dot{B}}{x} = C \&c. \&c.$$

The three preceding cases are the first, second, and third propositions in the author's chapter on series, which contains four other propositions equally general and important; but for these we must refer the reader to the tract itself.

Since the publication of Simpson's work above referred to, a variety of other treatises have appeared either wholly or in part devoted to this subject, besides numerous memoirs in all the principal academies and learned societies in Europe. It will be impossible to enter upon these at any considerable length within the limits of this article, and we shall therefore merely select two or three of the principal authors whose methods are the most eligible for the purposes of general summation.

Euler, in this, as in every other branch of analysis, has distinguished himself by the many new lights he has thrown upon this theory, and the general and elegant investigations that he has given of many very interesting problems relating to this doctrine. These investigations are found in various memoirs in the *Acta Petrop.* and in his "Institutiones calculi differentialis," as also in the first volume of his "Introduction in Analysin Infinitorum;" many of these, however, may be referred to the *Method of INCREMENTS and RECURRING SERIES*, which have been already treated of under those articles; the theory of circular series is also handled in his usually masterly manner, but for our purpose we shall prefer adopting the method employed by Landen in his "Mathematical Lucubrations," and shall therefore, in this place, limit our observations to Euler's differential method.

*Euler's Differential Method of Series.*—Let there be proposed the general series

$$S = a x + b x^2 + c x^3 + d x^4 + \&c.$$

in which  $a, b, c, d, \&c.$  are constant and positive quantities,  $x$  being indeterminate. This series Euler transforms into the following equivalent series, *viz.*

$$S = \frac{x}{1-x} a + \frac{x^2}{(1-x)^2} \Delta a + \frac{x^3}{(1-x)^3} \Delta^2 a + \frac{x^4}{(1-x)^4} \Delta^3 a + \&c.$$

In which  $\Delta a, \Delta^2 a, \Delta^3 a,$  denote the first terms of the first, second, third, &c. differences of  $a, b, c, \&c.$  observing that the leading term is always supposed to be taken from the following, so that when the terms diminish, this difference will be negative. It is obvious here, as in the other differential series we have had occasion to notice, that when

any order of differences vanish, the transformed series will be finite, but in other cases infinite, the same as that whence it is derived.

Let, for example, the series

$$S = x + 2x^2 + 3x^3 + 4x^4 + \&c.$$

be the one proposed. Here the first differences are  $1, 1, 1, \&c.$  and, consequently, the second differences are zero; that is, we have  $a = 1,$  and  $\Delta a = 1;$  so that we have

$$S = \frac{x}{1-x} a + \frac{x^2}{(1-x)^2} \Delta a = \frac{x}{(1-x)^2}.$$

Hence, by substituting  $x = 1, \frac{1}{2}, \frac{1}{3}, \&c.$  we obtain

$$x = 1; S = 1 + 2 + 3 + 4 + \&c. = \frac{1}{(1-1)^2} = \infty$$

$$x = \frac{1}{2}; S = \frac{1}{2} + \frac{2}{4} + \frac{3}{8} + \frac{4}{16} + \&c. = \frac{\frac{1}{2}}{(1-\frac{1}{2})^2} = 2$$

$$x = \frac{1}{3}; S = \frac{1}{3} + \frac{2}{9} + \frac{3}{27} + \frac{4}{81} + \&c. = \frac{\frac{1}{3}}{(1-\frac{1}{3})^2} = \frac{3}{4}$$

&c. &c. &c.

Again, let the proposed series be

$$S = x + 3x^2 + 5x^3 + 7x^4 + \&c.$$

Here  $a = 1, \Delta a = 2, \Delta^2 a = 0;$  therefore

$$S = \frac{x}{1-x} a + \frac{x^2}{(1-x)^2} \Delta a = \frac{x^2 + x}{(1-x)^2}.$$

Making therefore, as before,  $x = 1, \frac{1}{2}, \frac{1}{3}, \&c.$  we have

$$x = 1; S = 1 + 3 + 5 + 7 + \&c. = \frac{1+1}{(1-1)^2} = \infty$$

$$x = \frac{1}{2}; S = \frac{1}{2} + \frac{3}{4} + \frac{5}{8} + \frac{7}{16} + \&c. = \frac{\frac{1}{2} + \frac{1}{2}}{(1-\frac{1}{2})^2} = 3$$

$$x = \frac{1}{3}; S = \frac{1}{3} + \frac{3}{9} + \frac{5}{27} + \frac{7}{81} + \&c. = \frac{\frac{1}{3} + \frac{1}{3}}{(1-\frac{1}{3})^2} = 1$$

Without farther examples, it is obvious, that a most extensive class of summable series may be drawn from this one simple principle, by merely changing the values of  $x;$  and those of  $a, b, c, d, \&c.$  being so assumed, that a certain order of their difference may vanish, which will always happen, if they be made to represent any order of polygonal or figurate numbers, or any order of powers whatever. This method, however, is not limited to finding summable series, it may frequently be employed to great advantage in approximating towards the real value of slowly converging series that are not summable in any finite form, as for example, the series

$$1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} - \frac{1}{6} + \&c. = \text{hyp. log. } 2;$$

putting this under the form

$$S = x + \frac{1}{2} x + \frac{1}{3} x^2 + \frac{1}{4} x^3 + \&c.$$

we have  $a = 1, \Delta a = -\frac{1}{2}, \Delta^2 a = \frac{1}{3}, \Delta^3 a = -\frac{1}{4} \&c.$

whence

$$S = \frac{x}{1-x} a + \frac{x^2}{(1-x)^2} \Delta a + \frac{x^3}{(1-x)^3} \Delta^2 a + \&c.$$

will

will become, by making  $x = -1$ ,

$$S = \frac{-1}{2} - \frac{1}{2 \cdot 4} - \frac{1}{3 \cdot 8} - \frac{1}{4 \cdot 16} - \frac{1}{5 \cdot 32} - \dots = -1 + \frac{1}{2} - \frac{1}{3} + \frac{1}{4} - \frac{1}{5} + \dots$$

whence, by changing signs, we have

$$1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} - \dots = \text{hyp. log. } 2$$

$$= \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 4} + \frac{1}{3 \cdot 8} + \frac{1}{4 \cdot 16} + \frac{1}{5 \cdot 32} + \dots$$

which latter series, though indefinite like the first, is so much more converging, that 25 terms of it will give a result as true as 10,000 terms of the original series.

The same formula is also applicable to certain diverging series, but we can only give some of the most remarkable results, as

$$1 - 1 + 1 - 1 + 1 - 1 + \dots = \frac{1}{2}$$

$$1 - 2 + 3 - 4 + 5 - 6 + \dots = \frac{1}{4}$$

$$1 - 4 + 9 - 16 + 25 - \dots = 0$$

$$1 - 3 + 9 - 27 + 81 - \dots = \frac{1}{4}$$

$$1 - 1 \cdot 2 + 1 \cdot 2 \cdot 3 - 1 \cdot 2 \cdot 3 \cdot 4 + 1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 - \dots = 0.5963473621237$$

Euler also employed other methods for summable series, which we have not referred to either in the above article, or in the articles INCREMENTS OR RECURRING SERIES, one of the most general of which is by means of certain fluxional operations; but as this has been carried to a greater extent by Lorgna, in his tract "de Seriebus convergentibus," we shall defer any further mention of it till we come to an explanation of Lorgna's method.

We ought to give here some account of the differential method of Maferes and Hutton, but our article having already been carried to a greater extent than is usual for mathematical subjects, we must limit ourselves to giving merely the theorems, and leave the application of them to the ingenuity of the reader.

8. *Maferes differential Formula for slowly converging Series.*

Let  $a + bx + cx^2 + dx^3 + \dots$

represent any series, and  $D'$ ,  $D''$ ,  $D'''$ , &c. the first terms of the successive order of differences of the co-efficients  $a, b, c, d$ , &c. which are supposed continually to diminish, then will the sum of the above series be expressed by the differential series

$$a - \frac{b}{1+x} - \frac{D'x^2}{(1+x)^2} - \frac{D''x^3}{(1+x)^3} - \dots$$

which is necessarily converging, provided  $x$  be equal to, or greater than unity. By means of this series, the author finds the circumference of the circle from the series

$$1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \dots$$

true to seven places of decimals, by the summation of ten terms, whereas, in its original form, 10,000 of its terms will only give two decimals correct. For a further illustration of this method, the reader is referred to the Phil. Transf. for 1775, or to the author's Treatise on Converging Series.

9. *Hutton's Method for slowly converging Series.*—This method applies only to those series whose terms are alternately plus and minus, as  $a - b + c - d + \dots$  the total sum of which series is given alternately in excess and defect,

by the successive quantities  $\frac{a}{2}, \frac{3a-b}{4}, \frac{7a-4b+c}{8}, \frac{15a-11b+3c-d}{16}, \frac{31a-26b+16c-6d+c}{32}$ , &c.

&c.; each of these quantities, as we have itated above, is an approximation towards the whole sum; the first in excess, the second in defect, the third in excess, and so on; but each is a nearer approximation than the preceding. The general formula for  $n$  terms is

$$\frac{1}{2^n} \left\{ (2^n - 1)a - (A - n)b - \left( B - \frac{n(n-1)}{1 \cdot 2} \right) c - \left( C - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} \right) d - \dots \right\}$$

The method of applying this formula to computation, however, is such, that we must refer the reader for an explanation of it to the author's Miscellaneous Tracts, published in 4to. in 1778, or to the new edition of the same in 3 vols. 8vo. published in 1812.

10. *Lorgna's Method of Series.*—This consists in multiplying the terms of the proposed series by such powers of an indeterminate quantity, that the fluxion of the whole series being taken, and then divided by  $x$ , there shall result a known series, from which the sum of the original one may be readily derived. Thus, let there be proposed the series,

$$\frac{1}{p+q} + \frac{1}{p+2q} + \frac{1}{p+3q} + \dots$$

Multiply each term successively by

$$x^{\frac{p}{q}+1}, x^{\frac{p}{q}+2}, x^{\frac{p}{q}+3}, \dots$$

and there results

$$\frac{x^{\frac{p}{q}+1}}{p+q} + \frac{x^{\frac{p}{q}+2}}{p+2q} + \frac{x^{\frac{p}{q}+3}}{p+3q} + \dots$$

Make the sum of this series =  $S$ , and then taking the fluxion on both sides, we have

$$\frac{q \dot{S}}{x} = x^{\frac{p}{q}} + x^{\frac{p}{q}+1} + x^{\frac{p}{q}+2} + x^{\frac{p}{q}+3} + \dots$$

$$\text{or } \frac{q \dot{S}}{x^{\frac{p}{q}+1}} = 1 + x + x^2 + x^3 + \dots = \frac{1}{1-x};$$

whence  $\dot{S} = \frac{x^{\frac{p}{q}+1}}{q(1-x)}$ ; and consequently,

$$S = \int \frac{x^{\frac{p}{q}+1}}{1-x} = \frac{x^{\frac{p}{q}+1}}{p+q} + \frac{x^{\frac{p}{q}+2}}{p+2q} + \frac{x^{\frac{p}{q}+3}}{p+3q};$$

which, by making  $x = 1$ , becomes the same as the series originally proposed, viz.

$$\frac{1}{p+q} + \frac{1}{p+2q} + \frac{1}{p+3q} + \frac{1}{p+4q} + \dots$$

It must be observed, however, that in all such expressions, the fluent must be so taken, as to vanish when  $x = 0$ , and to be perfectly integral when  $x = 1$ .

By a similar process, the author finds the sum of the series,

$$\frac{1}{p+q} - \frac{1}{p+2q} + \frac{1}{p+3q} - \frac{1}{p+4q} + \dots$$

to be equal to  $\frac{1}{q} \int \frac{x^{\frac{p}{q}} \dot{x}}{1+x}$ ; the fluent being taken under

the same restriction as before. And in nearly the same way he finds the sum of  $n$  terms of the former to be

$$\Sigma = \frac{1}{q} \left\{ \int \frac{x^{\frac{p}{q}} \dot{x}}{1-x} - \int \frac{x^{\frac{p+qn}{q}} \dot{x}}{1-x} \right\}$$

and the latter,

$$\Sigma = \frac{1}{q} \left\{ \int \frac{x^{\frac{p}{q}} \dot{x}}{1+x} - \int \frac{x^{\frac{p+qn}{q}} \dot{x}}{1+x} \right\}$$

In a similar manner, M. Lorgna finds for the infinite sum of

$$\frac{1}{(p+q)m} \pm \frac{1}{(p+2q)m^2} + \frac{1}{(p+3q)m^3} \pm \&c. -$$

$$S = \frac{1}{q} \int \frac{x^{\frac{p}{q}} \dot{x}}{m \pm x}$$

$$\Sigma = \frac{1}{q} \int \frac{(m^n - x^n) x^{\frac{p}{q}} \dot{x}}{m^n (m - x)}, \text{ when the signs are all plus;}$$

$$\text{and } \Sigma = \frac{1}{q} \int \frac{(m^{2n} - x^{2n}) x^{\frac{p}{q}} \dot{x}}{m^{2n} (m + x)}, \text{ when alternately plus}$$

and minus.

For a farther illustration of this method, we refer the reader to Clarke's translation of Lorgna's treatise, "De Seriebus Convergentibus," 4to. 1779.

11. *Circular Series.*—We have stated, when illustrating the methods of summation employed by the Bernoullis, that James, although he had discovered several curious properties of the series,

$$\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \&c.$$

had not been able to find its sum; but this his brother John afterwards effected, and the solution of it is published in the 4th volume of his "Opera Omnia." Bernoulli found this sum to depend upon the rectification of the circle, shewing that it is equal to one-sixth of the square of the semi-circumference of a circle, whose radius = 1. This result he drew from the known series, which expresses the fine of an arc in terms of the arc, viz.

$$\text{fin. } x = x - \frac{x^3}{2 \cdot 3} + \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{x^7}{2 \cdot 3 \cdot \dots \cdot 7} + \&c.;$$

which, when fin.  $x = 0$ , becomes, after dividing by  $x$ ,

$$0 = 1 - \frac{1}{2 \cdot 3} x^2 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} x^4 - \frac{1}{2 \cdot 3 \cdot \dots \cdot 7} x^6 + \&c.$$

Or writing  $x = \frac{1}{z}$ ;

$$0 = 1 - \frac{1}{2 \cdot 3 z^2} + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5 z^4} - \frac{1}{2 \cdot 3 \cdot \dots \cdot 7 z^6} + \&c.$$

Again, multiplying by  $z^{2n}$ ,

$$0 = z^{2n} - \frac{1}{2 \cdot 3} z^{2n-2} + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} z^{2n-4} - \&c.$$

Now the sum of the roots of every equation of this form

being equal to the co-efficient of the second term with its sign changed, we have

$$z'^2 + z''^2 + z'''^2 + \&c.,$$

$$\text{or } \frac{1}{z'^2} + \frac{1}{z''^2} + \frac{1}{z'''^2} + \&c. = \frac{1}{6};$$

denoting by  $z'^2, z''^2, z'''^2, \&c.$ , or  $\frac{1}{z'^2}, \frac{1}{z''^2}, \frac{1}{z'''^2}, \&c.$  the successive roots of the above equation.

But we know that the values of  $x$ , answering to the case of fin.  $x = 0$ , are  $\pi, 2\pi, 3\pi, 4\pi, \&c.$ ;  $\pi$  denoting the semi-circumference: substituting, therefore, these successive values of  $x$ , we have

$$\frac{1}{\pi^2} + \frac{1}{2^2 \pi^2} + \frac{1}{4^2 \pi^2} + \frac{1}{3^2 \pi^2} + \frac{1}{4^2 \pi^2} + \&c. = \frac{1}{6},$$

$$\text{or } \frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \&c. = \frac{\pi^2}{6}.$$

Landen's method depends upon exactly the same principles; but he has rendered it more general, and exhibits several very remarkable series of this kind. He first deduces the formulæ for expressing the sums of the several powers of the roots,  $a, b, c, \&c.$  of any equation

$$x^n + A x^{n-1} + B x^{n-2} + C x^{n-3} + \&c. = 0;$$

$$\text{viz. if } S' = a + b + c + \&c.$$

$$S'' = a^2 + b^2 + c^2 + \&c.$$

$$S''' = a^3 + b^3 + c^3 + \&c.$$

$$\text{then } S' = -A$$

$$S'' = -2B - A S'$$

$$S''' = -3C - B S' - A S''$$

$$S^{\text{iv}} = -4D - C S' - B S'' - A S'''$$

$$\&c. \quad \&c.$$

Then from the two series for the sine and cosine of any arc  $x$ , viz.

$$\text{fin. } x = x - \frac{x^3}{2 \cdot 3} + \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{x^7}{2 \cdot 3 \cdot \dots \cdot 7} + \&c.$$

$$\text{cof. } x = 1 - \frac{x^2}{2} + \frac{x^4}{2 \cdot 3 \cdot 4} - \frac{x^6}{2 \cdot 3 \cdot \dots \cdot 6} + \&c.$$

he derives the sum of their roots, when fin.  $x = 0$ , and cof.  $x = 0$ ; and then, from the preceding formula for the sums of the squares, cubes, &c. of the roots of an equation, draws the values of the several powers of those quantities.

Thus in the series for the cosine, when cof.  $x = 0$ , we have for the several roots, (denoting the quadrant or  $\frac{\pi}{2}$  by  $\phi$ .)

$$\left. \begin{aligned} &\frac{1}{\phi^2} + \frac{1}{3^2 \phi^2} + \frac{1}{5^2 \phi^2} + \frac{1}{7^2 \phi^2} \\ & - \frac{1}{\phi^4} - \frac{1}{3^2 \phi^4} - \frac{1}{5^2 \phi^4} - \frac{1}{7^2 \phi^4} \end{aligned} \right\} = 0;$$

there being no second term, but the sum of these squared, viz.

$$\left. \begin{aligned} &\frac{1}{\phi^2} + \frac{1}{3^2 \phi^2} + \frac{1}{5^2 \phi^2} + \frac{1}{7^2 \phi^2} \\ & \frac{1}{\phi^4} + \frac{1}{3^2 \phi^4} + \frac{1}{5^2 \phi^4} + \frac{1}{7^2 \phi^4} \end{aligned} \right\} =$$

# SERIES.

$$\frac{2}{\phi} + \frac{2}{2^2 \phi^2} + \frac{2}{5^2 \phi^2} + \frac{2}{7^2 \phi^2} = S'' = \frac{1}{6^2} \approx$$

$$1 + \frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} = \frac{\phi^2}{2}.$$

In a similar manner we have

$$\frac{1}{1^4} + \frac{1}{3^4} + \frac{1}{5^4} + \frac{1}{7^4} + \&c. \frac{\phi^4}{6^4};$$

and on the same principle, the sum of the series,

$$1 + \frac{1}{3^{2n}} + \frac{1}{5^{2n}} + \frac{1}{7^{2n}} + \&c.$$

may be found,  $n$  being any positive number whatever.

Euler's method is still more general than Landen's, but it depends upon principles of very nearly the same origin; we must, however, limit ourselves to giving a few of the principal results. Representing by  $\pi$  the semi-circumference to radius 1, he shews that

$$1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \&c. = \frac{2^0}{1 \cdot 2 \cdot 3} \cdot \frac{1}{1} \pi^2$$

$$1 + \frac{1}{2^4} + \frac{1}{3^4} + \frac{1}{4^4} + \&c. = \frac{2^0}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} \cdot \frac{1}{3} \pi^4$$

$$1 + \frac{1}{2^6} + \frac{1}{3^6} + \frac{1}{4^6} + \&c. = \frac{2^1}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} \cdot \frac{1}{3} \pi^6$$

$$\&c. \qquad \&c. \qquad \qquad \qquad = \qquad \&c.$$

where the law of the first multiplier is obvious, but the coefficients of  $\pi^2$ ,  $\pi^4$ , &c. are not so easily seen: those for the

following powers are  $\frac{3}{5} \pi^8$ ,  $\frac{5}{3} \pi^{10}$ ,  $\frac{691}{105} \pi^{12}$ , &c.

If each of these series be multiplied by their first fraction, they give

$$\frac{1}{2^2} + \frac{1}{4^2} + \frac{1}{6^2} + \&c. = \frac{1}{2^2} \cdot \frac{2^0}{1 \cdot 2 \cdot 3} \cdot \frac{1}{1} \pi^2$$

$$\frac{1}{2^4} + \frac{1}{4^4} + \frac{1}{6^4} + \&c. = \frac{1}{2^4} \cdot \frac{2^2}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} \cdot \frac{1}{3} \pi^4$$

$$\&c. \qquad \&c. \qquad \qquad \qquad = \qquad \&c.;$$

and subtracting these from the first, we have

$$1 + \frac{1}{3^2} + \frac{1}{5^2} + \&c. = \frac{2^2 - 1}{2^2} \cdot \frac{2^0}{1 \cdot 2 \cdot 3} \cdot \frac{1}{1} \pi^2$$

$$1 + \frac{1}{3^4} + \frac{1}{5^4} + \&c. = \frac{2^4 - 1}{2^4} \cdot \frac{2^2}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} \cdot \frac{1}{3} \pi^4$$

$$\&c. \qquad \&c. \qquad \qquad \qquad = \qquad \&c.$$

Again, subtracting the first from these last, we find the sum of the powers under the alternate signs plus and minus, and so on, almost in endless variety.

Other series, whose sums are found in nearly the same manner, are as follows, *viz.*

$$1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \&c. = \frac{\pi}{4}$$

$$1 + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \&c. = \frac{\pi^2}{8}$$

$$1 - \frac{1}{3^3} + \frac{1}{5^3} - \frac{1}{7^3} + \&c. = \frac{\pi^3}{3^2}$$

$$1 + \frac{1}{3^4} + \frac{1}{5^4} + \frac{1}{7^4} + \&c. = \frac{\pi^4}{96}$$

$$\&c. \qquad \qquad \qquad \&c. \qquad \qquad \qquad = \qquad \&c.$$

For a great variety of other series of this kind, see Euler's "Introductio in Analysin Infinitorum," and his "Institutiones Calculi Differentialis." See also Spence's "Essay on the Theory of the various Orders of Logarithmic Transcendents," 4to. 1809; in which several series, somewhat similar to the above, but which were not summable by Euler's method, are treated of, and investigated in a very able manner.

We ought perhaps to apologize to such of our readers who are not interested in mathematical enquiries, for the length to which we have extended this article; but those who are, will not, we presume, be displeased to find in a condensed form a general view of the first introduction, and successive improvements, which have been made in this important branch of analysis. We have, of course, been obliged to pass over in silence many authors who have written on this subject; but we have endeavoured to include all those who have introduced into the doctrine any methods distinctly different from those who preceded them, at least, if we except Mr. Spence's method, published in his "Logarithmic Transcendents," and that of M. Arbogast, given in his "Calcul des Derivations." We had indeed, in the first instance, intended to give an illustration of the principles of these two authors; but the length to which the article has already extended, and the nature of their notation, which render necessary a considerable degree of previous explanation, put it out of our power to execute this part of our plan, and we can therefore do nothing more than refer the reader for information to the works themselves; we refer him also to the "Calcul des Differences Finies," by La Croix, and to an ingenious memoir by professor Vince, in the 72d volume of the Philosophical Transactions.

As the preceding article is arranged wholly with reference to the historical order of the subject, we intend, in conclusion, to furnish the reader with a general synopsis of the doctrine of series for the advantages of practical operations.

12. *General Synopsis for the Summation of Series.*—In the following tablet,  $S$  denotes the sum of a finite number of terms ( $n$ ), and  $\Sigma$  the sum of an infinite number.

1. To find whether the sum of any proposed series be finite or infinite; let  $p, q, r$ , be any three equidistant terms; then, if  $p(q-r) > r(p-q)$ , the sum is finite; but if  $p(q-r) < r(p-q)$ , it is infinite.

2. The general term of a series, when any order  $m$  of its differences vanish, is of the form,

$$T = A n^m + B n^{m-1} + C n^{m-2} + \&c.$$

and its sum of the form,

$$\Sigma = A' n^{m+1} + B' n^m + C' n^{m-1} + \&c.$$

the values  $A, B, C$ , &c. being found as stated in art 5, and those of  $A', B', C'$ , &c. in a similar manner.

### 3. Simple arithmetical Series.

$$a + (a+d) + (a+2d) + (a+3d) \dots a + (n-1)d$$

$$(\Sigma) \text{ Infinite } (S) = \frac{n}{2} (2a + (n-1)d).$$

If the series decrease, then  $d$  is negative, and

$$(S) = \frac{n}{2} (2a - (n-1)d).$$

### 4. Simple geometrical Series.

$$a + ra + r^2a + r^3a \dots r^{n-1}a$$

$$(\Sigma) = \frac{a}{1-r} \cdot (S) = \frac{r^n - 1}{r - 1} a$$

### 5. Powers

# SERIES.

## 5. Powers of Arithmetics.

$$(S) = \frac{n^{r+1}}{(r+1)p} + \frac{n^r}{2} + \frac{p r n^{r-1}}{3 \cdot 4} - \frac{r(r-1)(r-2)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} p^3 n^{r-3} \\ + \frac{1}{6} \frac{r(r-1)(r-2)(r-3)(r-4)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} p^5 n^{r-5} - \frac{1}{30} \frac{r(r-1)(r-2) \dots (r-6)}{2 \cdot 3 \dots 8} p^7 n^{r-7} \\ + \frac{1}{42} \frac{r(r-1)(r-2) \dots (r-8)}{2 \cdot 3 \dots 9} p^9 n^{r-9} - \&c. \\ - \frac{m^{r+1}}{(r+1)p} - \frac{m^r}{2} - \frac{r p m^{r-1}}{3 \cdot 4} + \frac{r(r-1)(r-2)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} p^3 m^{r-3} - \&c$$

continued till they terminate. The co-efficients are the same as  $\frac{1}{A}$ ,  $\frac{1}{B}$ , &c. N<sup>o</sup> 11.

This form includes all the powers of the natural series, of which we have given the particular forms to the fifth power, under art. 3.

## 6. Series of figurate Numbers.

$$1 + m + \frac{m(m+1)}{1 \cdot 2} + \frac{m(m+1)(n+2)}{1 \cdot 2 \cdot 3} + \frac{m(m+1)(m+2)(m+3)}{1 \cdot 2 \cdot 3 \cdot 4} + \&c \\ (S) = \frac{n(n+1)(n+2)(n+3) \text{ to } m \text{ terms,}}{1 \cdot 2 \cdot 3 \cdot 4 \text{ to } m \text{ terms.}}$$

See particular results, art. 3.

## 7. Series of compound Arithmetics.

$$(m+e)(p+e) + (m+2e)(p+2e) + \dots + (m+ne)(p+ne) \\ (S) = nmp + \frac{n+1}{2} (m+p)e + \frac{(n+1)(2n+1)}{6} e^2$$

## 8. Series of compound geometrical Numbers.

$$(b-m)(c-p)e^e + (b-2m)(c-2p)e^{e+p} + (b-3m)(c-3p)e^{e+2p} + \&c. \\ (\Sigma) = \frac{e^e}{1-e^e} \left\{ bc - \frac{b p + c m}{1-e^e} + \frac{m p (1+e^e)}{(1-e^e)^2} \right\} \\ (S) = (\Sigma) - \frac{e^{e+pn}}{1-e^e} \left\{ (b-mn)(c-pn) - \frac{(b-mn)n + (c-pn)m}{1-e^e} + \frac{m p (1+e^e)}{(1-e^e)^2} \right\}$$

## 9. Series of compound figurate Numbers.

$$1 + mx + \frac{m(m+1)}{1 \cdot 2} x^2 + \frac{m(m+1)(m+2)}{1 \cdot 2 \cdot 3} x^3 + \frac{m(m+1)(m+2)(m+3)}{1 \cdot 2 \cdot 3 \cdot 4} + \&c. \\ (\Sigma) = \frac{1}{(1-x)^m}$$

## 10. Series of the Reciprocals of figurate Numbers.

$$1 + \frac{1}{m} + \frac{1 \cdot 2}{m(m+1)} + \frac{1 \cdot 2 \cdot 3}{m(m+1)(m+2)} + \frac{1 \cdot 2 \cdot 3 \cdot 4}{m(m+1)(m+2)(m+3)} + \&c. \\ (\Sigma) = \frac{m-1}{m-2}$$

## 11. Reciprocals of the Powers of Arithmetics.

$$\frac{1}{a^n} + \frac{1}{(a+d)^n} + \frac{1}{(a+2d)^n} + \frac{1}{(a+3d)^n} + \dots + \frac{1}{(a+(n-1)d)^n} \\ (S) = \frac{p^{n-1} \curvearrowright 1}{(m-1)a^{n-1}d} - \frac{p^m \curvearrowright 1}{2a^m} + \frac{(p^{m-1} \curvearrowright 1)md}{2 \cdot A \cdot a^{i+1}} - \frac{(p^{n+3} \curvearrowright 1)m(m+1)(m+2)d^3}{2 \cdot 3 \cdot 4 \dots B a^{n+3}} \\ + \frac{(p^{m+5} \curvearrowright 1)m(m+1)(m+2) \dots (m+4)d^5}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \dots C a^{n+5}} - \&c.$$

where the law of continuation is obvious,  $p$  being  $= \frac{a}{a+n}$ , and the values of  $\frac{1}{A}$ ,  $\frac{1}{B}$ ,  $\frac{1}{C}$ , &c. being derived as follows,

*viz.* denoting these respectively by  $\frac{1}{1\phi}$ ,  $\frac{1}{2\phi}$ ,  $\frac{1}{3\phi}$ , &c.

$$\frac{1}{1\phi} = \frac{1}{6}$$

$$\frac{1}{2\phi} = \frac{3}{10} - 2 \cdot \frac{1}{1\phi}$$

$$\frac{1}{3\phi} = \frac{5}{14} - 3 \cdot \frac{1}{2\phi} + 5 \cdot \frac{1}{1\phi}$$

$\frac{1}{4\phi}$  = &c. &c. and generally

$$\frac{1}{n\phi} = \frac{n}{2n+4} - \frac{n+1}{2} \frac{1}{1\phi} + \frac{(n+1)n(n-1)}{2 \cdot 3 \cdot 4} \frac{1}{2\phi} - \frac{(n+1)n(n-1)(n-2)(n-3)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} \frac{1}{3\phi} \text{ \&c.}$$

### 12. Fractional Series of the following Form.

$$(1.) \frac{m}{\beta} + \frac{m(m+p)}{\beta(\beta+p)} + \frac{m(m+p)(m+2p)}{\beta(\beta+p)(\beta+2p)} + \dots + \frac{m(m+p) \dots (m+(n-1)p)}{\beta(\beta+p) \dots (\beta+(n-1)p)}$$

$$(\Sigma) = \frac{m}{\beta - p - m}$$

$$(2.) \frac{1}{(p+q)(m+r)} \pm \frac{1}{(p+2q)(m+2r)} + \frac{1}{(p+3q)(m+3r)} \pm \text{\&c.} \frac{1}{(p+nq)(m+nr)}$$

$$(\Sigma) = \frac{1}{pqr} \times \int \frac{(x^p - x^q)^n x^r}{1+x}$$

$$(3.) \frac{1}{(p+q)\beta} \pm \frac{1}{(p+2q)\beta^2} + \frac{1}{(p+3q)\beta^3} \pm \text{\&c.} \dots \frac{1}{(p+nq)\beta^n}$$

$$(\Sigma) = \frac{1}{q} \int \frac{(\beta^n - x^n) x^p}{\beta^n (\beta+x)} \cdot (\Sigma) = \frac{1}{q} \int \frac{x^p}{\beta+x}$$

where  $\beta$  must be affirmative, and not less than unity.

$$(4.) \frac{a}{b(b+c)} + \frac{a}{(b+c)(b+2c)} + \frac{a}{(b+2c)(b+3c)} + \text{\&c.} \dots \frac{a}{(b+(n+1)c)(b+nc)}$$

$$(\Sigma) = \frac{na}{b(b+nc)} \cdot (\Sigma) = \frac{a}{bc}$$

$$(5.) \frac{a}{b(b+c)(b+2c)} + \frac{a+c}{(b+c)(b+2c)(b+3c)} + \frac{a+2c}{(b+2c)(b+3c)(b+4c)}$$

$$+ \text{\&c.} \dots \frac{a+(n+1)c}{\left\{ b+(n-1)c \right\} (b+nc) \left\{ b+(n+1)c \right\}}$$

$$(\Sigma) = \frac{(2ab+ac-bc)n + (ac+bc)n^2}{2b(b+c)(b+nc)(b+(n+1)c)}$$

$$(6.) \frac{a}{a+1} + \frac{a+b}{(a+1)(a+1+b)} + \frac{a+2b}{(a+1)(a+1+b)(a+1+2b)}$$

$$+ \text{\&c.} \dots \frac{a+(n-1)b}{(a+1)(a+1+b) \dots (a+1+(n-1)b)}$$

$$(\Sigma) = 1 - \frac{1}{(a+1)(a+1+b) \dots (a+1+(n-1)b)}$$

$$(7.) a \cdot c + (a+b)cq + (a+2b)cq^2 + (a+3b)cq^3 + \text{\&c.}$$

$$(\Sigma) = \frac{ac(q^n-1) + nbcq^n}{q-1} - \frac{bcq(q^n-1)}{(q-1)^2}$$

$$(8.) \frac{a}{c} + \frac{a+b}{cq} + \frac{a+2b}{cq^2} + \frac{a+3b}{cq^3} + \&c.$$

$$(S) = \frac{\{a(q-1) + b\} (q^n - 1) - nb(q-1)}{cq^{n-1}(q-1)^2}$$

For a great variety of other fractional series, see Clarke's translation of Lorgna's Series; for the several differential formulæ, our articles 3, 6, 7, 8, and 9; for the summation of RECURRING Series, see that article; for the most useful logarithmic series, see LOGARITHMS; and for various trigonometrical series, see the articles SINES, and TRIGONOMETRY.

SERIGNAC, in *Geography*, a town of France, in the department of the Finistère; 10 miles N. of Carhaix.

SERIGNAN, a town of France, in the department of the Hérault; 6 miles S. of Beziers.

SERIGNI, a sea-port town of the island of Java, in the straits of Sunda, belonging to the king of Bantam.

SERIGO. See CERIGO.

SERIGO, a town of Italy, on the lake Como; 27 miles N. of Como.

SERJIHEYODOUC, a town of Chinese Tartary, in the country of the Monguls. N. lat.  $42^{\circ} 15'$ . E. long.  $102^{\circ} 34'$ .

SERIKOTCHE, a town of Persia, in the province of Chorasan or Khorassan; 195 miles N. of Herat.

SERIMSAH, a town of Egypt; 16 miles S. of Damietta.

SERIN, or SERAIN, a river of France, which runs into the Yonne, between Auxerre and Joigny.

SERIN, or *Serinus*, in *Ornithology*, the name of a small bird; a species of the Fringilla in the Linnæan system, common in Germany and Italy, and called by the Austrians *baerngril*, or *birngryl*. Its back is of a reddish-brown, and its head yellow; the colour being deeper in the male, and paler in the female; the rump is of a beautiful yellowish-green, as is also the breast; the belly is white, and the sides have some oblong blackish spots; the tail, and long feathers of the wings, are black, and a little greenish at their extremities; the beak is very thick, strong, and short, and is very sharp at the point. It is kept in cages, and sings very sweetly.

SERIN of Surinam. See PIPRA *Cristata*.

SERIN of the Canaries. See FRINGILLA *Canaria*.

SERIN of Jamaica. See FRINGILLA *Canis*.

SERINDA, in *Ancient Geography*, a town of India, on this side of the Ganges, the inhabitants of which paid great respect to the emperor Julian.

SERINE, in *Geography*, a town of European Turkey, in the province of Macedonia; 44 miles S.E. of Saloniki.

SERINEAH, a town of Bengal, 18 miles S. of Purneah.

SERINETTE, a bird organ, said in the Encyclopédie to be an invention of Barbary. The pitch is very high, being in unison with the larigot stop in French organs, and with our 15th. It is used to teach birds little tunes, by those unable to play on the flageolet. Its compass is only an octave, or 13 pipes, as no base is ever wanted.

SERINGAPATAM, in *Geography*, a city of Hindoostan, and capital of Myfore, situated on an island in the Cauvery, which is here about five feet deep, and runs over a rocky channel, about 290 or 300 miles from Madras. The length of this isle is about four miles, and its breadth about four and a half miles; the western side being allotted to the fortrefs,

which occupied 2000 yards, distinguished by regular outworks, magnificent palaces, and lofty mosks; for Tippoo and his father were both Mahometans, nor were they averse from the persecution of the Hindoos and Christians. The environs were decorated with noble gardens; and among other means of defence was the "bound hedge," as it was called, consisting of every thorny tree and caustic plant of the climate, planted to the breadth of from 30 to 50 feet. Covered on the north and south by the river, this fortress was defended till the peace of 1792 by a single rampart; the east and west faces being much weaker, were strengthened by double walls and ditches, by outworks before the gates, by a circular work upon the south-east angle, and by several formidable cavaliers within and upon the southern rampart. The rampart, which is thick and strong, varies in height from 20 to 35 feet and upwards; the whole of the revêtement, except the north-west bastion, is composed of granite cut in large oblong pieces, laid in cement, transversely in the walls. The ditches are cut out of the solid rock; a stone glacis extends along the north face. But the interior of the fort has few good buildings, and the town in general is mean. The old Myfore palace being in a ruined state, has been converted into a military storehouse. The sultan's palace is a magnificent edifice, in the Asiatic style, but much disfigured by a high wall, and a number of unfinished buildings round it. The great mosk is covered with the finest chunam (or polished cement), and ornamented with lofty minarets. In the year 1792, lord Cornwallis laid siege to this city, and compelled Tippoo, king of Myfore, to a peace, by which he made a cession of great part of his dominions, and agreed to pay three crores and thirty lacks of rupees towards the expenses of the war. In the year 1799, the British troops, after a short siege of a few days, took it by assault. The loss of the besiegers amounted to 22 officers killed, and 45 wounded, 181 Europeans rank and file killed, 622 wounded, and 22 missing; 119 natives killed, 420 wounded, and 100 missing. There were in the fort 13,739 regular infantry; and without the fort and in the intrenchments of the island 8100. The loss must have been very great, as in the assault only, 24 principal officers were killed, and seven wounded, besides Tippoo himself, who received a shot in his head. There were found in the forts 373 brass guns, 60 mortars, 11 howitzers, 466 iron guns, and 12 mortars, 424,400 round shot, 520,000 lbs. of gunpowder, and 99,000 muskets, carbines, &c. Within the fort there were 11 large powder magazines, 72 expence magazines, 11 armouries, two cannon foundries, three buildings with magazines for boring guns and muskets, four large arsenals, and 17 other storehouses, containing accoutrements, swords, and other articles, besides many granaries abundantly stored with provisions of all kinds. Of treasure and jewels the total value was 2,535,804 star pagodas, or 1,143,216l. sterling. The fall of this city put the whole kingdom of Myfore, with all its resources, into the power of the British government. Tippoo's tons surrendered on the fall of Seringapatam. When the strength of the fortifications of all kinds of this place, and the number of Tippoo's troops and artillery are considered, our repeated successes afford a convincing proof that no climate or fortrefs can overcome British courage, conduct, and perseverance. N. lat.  $12^{\circ} 31' 45''$ . E. long.  $76^{\circ} 46' 45''$ .

SERINGHAM, an island of Hindoostan, in the river Cauvery, on which are two pagodas, much venerated by the Hindoos, and one peculiarly the object of devotion. In 1751 the French took possession of this pagoda, and in the following year it was taken by the English under major Lawrence; 4 miles N.E. of Trichinopoly.

**SERINHAEM**, a river of Brasil, which runs into the Atlantic, S. lat.  $12^{\circ} 50'$ .

**SERINO**, a town of Naples, in Principato Ultra; 19 miles S. of Benevento.

**SERINPALE**, a town of Africa, in the country of Cayor, on the left bank of the Senegal. N. lat.  $16^{\circ} 50'$ . W. long.  $15^{\circ} 50'$ .

**SERINPETA**, an island in the river Senegal, where the canoes of the country are constructed.

**SERIO**, a river of Italy, which runs into the Adda, at Pizzighitone.—Also, a department of Italy, composed of part of the Bergamasco; it contains 195,803 inhabitants, who elect 15 deputies. Its capital is Bergamo.

**SERIOIA**, in *Botany*, said by De Theis to be the diminutive of *σείρις*, the ancient appellation of *Succory* or *Endive*, which this plant resembles, especially in its leaves.—Linn. Gen. 404. Schreb. 533. Willd. Sp. Pl. v. 3. 1619. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 465. Juss. 171. Lamarck Illustr. t. 656. Gært. t. 159.—Class and order. *Syngenesia Polygamia Æqualis*. Nat. Ord. *Compositæ Semiflosculosæ*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Common calyx* simple, composed of linear, nearly equal, erect leaves. *Cor.* compound, imbricated, uniform, composed of numerous, equal, perfect flowers; proper of one ligulate, linear, truncated, five-toothed petal. *Stam.* Filaments five, capillary, very short; anthers cylindrical, tubular. *Pist.* Germen ovate; style thread-shaped, the length of the stamens; stigmas two, reflexed. *Peric.* none, except the unchanged calyx. *Seeds* oblong, the length of the calyx. Down capillary, feathered, with ten rays hairy at the sides. *Recept.* chaffy, deciduous, as long as the calyx.

Ess. Ch. Receptacle chaffy. Calyx simple. Seed-down rather hairy.

1. *S. lavigata*. Smooth Seriola. Linn. Sp. Pl. 1139. Desfont. Atlant. v. 2. 237. t. 216.—Herb smoothish. Leaves obovate, toothed.—Found in the fissures of rocks in Barbary, and in the island of Candia. It flowers, as indeed do all the rest, in July and August. *Roots* perennial, long, twisted, scaly at the top. *Stem* none. *Leaves* radical, in a circular cluster, stalked, smooth, remotely toothed, decurrent. *Flower-stalks* erect, slender, a little streaked, slightly branched, sometimes simple, almost leafless, mostly single-flowered. *Flowers* yellow.

2. *S. athenensis*. Rough Seriola. Linn. Sp. Pl. 1139. Desfont. Atlant. v. 2. 237. “Jacq. Obs. v. 4. 3. t. 79.”—Herb rough. Leaves obovate, slightly toothed.—Native of Italy, and near Mafcar in Barbary. *Root* annual. *Stems* branched, erect, hairy. *Leaves* hairy, stalked; upper ones sessile, embracing the stem. *Flower-stalks* erect, hairy, leafless above, unequal, single-flowered. *Flowers* yellow, forming a sort of corymbose panicle.

3. *S. cretensis*. Cretan Seriola. Linn. Sp. Pl. 1139. (“*Achyrophorus lufatus*, dentis leomis folio leviter dentato; Vaill. Act. 740.”)—Herb rough with hairs. Leaves runcinate.—Native of the island of Candia or Crete. We know not of any figure or description of this species. It rests on the above quoted authorities.

4. *S. urens*. Stinging Seriola. Linn. Sp. Pl. 1139. Allion. Pedem. t. 29. f. 1. “Schmüdel. Ic. t. 32.”—Herb stinging. Leaves toothed. Stem branched.—Native of Sicily and the south of Europe. *Root* annual, small, fibrous. *Stem* none. *Leaves* in a circular cluster, hairy, fringed. *Flower-stalks* erect, hairy, slightly branched. *Flowers* yellow. Linnæus discovered that the scales of the calyx are sharp with pungent little prickles, whence indeed the specific name.

VOL. XXXII.

**SERIPALA**, in *Ancient Geography*, a town of India, on this side of the Ganges, in the number of those which were situated to the east of the river Numadus, according to Ptolemy.

**SERIPHIIUM**, in *Botany*, a name applied to this genus on account of the analogy, in its habit and foliage, with *Artemisa pontica* of Pliny, called by the Greeks *Σερπίδιον*. The origin of this name may be traced to *Seriphion*, or, as it is now called, *Serpho*, an island in the Ægean sea, whose soil is of so dry and sterile a nature, as only to abound in plants of this rough kind. “This island,” says De Theis, “covered with rocks and mountains, has always been regarded as a melancholy retreat. A Greek once demanded of one of its inhabitants, what crime they punished with banishment? Perjury, was the answer. Why then, says the Greek, don’t you always perjure yourselves, in order that you may escape from such a horrible residence?” The French name *Armoiselle*, from *Armoise*, Worn wood, is expressive of its natural affinity to that genus.—Linn. Gen. 454. Schreb. 594. Mart. Mill. Dict. v. 4. Juss. 180. Lamarck Illustr. t. 722. Gært. t. 167.—Class and order. *Syngenesia Polygamia Segregata*. Nat. Ord. *Compositæ Nomenclatae*, Linn. *Corymbiferae*, Juss.

Obs. Willdenow and the editor of *Hortus Kewensis* have not adopted this genus. They refer the several species of it to *Artemisia* and *Stæbe*.

Gen. Ch. *Cal.* Perianth double; outer of five, roundish, imbricated, downy leaves; inner of five, erect, acuminate, awl-shaped, smooth, scaly leaves, which are twice as long as the outer ones, single-flowered. *Cor.* of one petal, funnel-shaped, shorter than the inner calyx; limb five-toothed. *Stam.* Filaments five, capillary; anthers cylindrical. *Pist.* Germen between the calyx and the flower; style thread-shaped; stigma rather cloven. *Peric.* none, except the unchanged, closed calyx. *Seed* solitary, oblong.

Ess. Ch. Calyx double, imbricated. Corolla of one petal, regular. Seed solitary, oblong, below the corolla.

1. *S. cinereum*. Heath-leaved Seriphium. Linn. Sp. Pl. 1316. (Stæbe cinerea; Willd. Sp. Pl. v. 3. 2406. Tamariscus æthiopicus, Coridis folio glabro; Pluk. Mant. 178. t. 297. f. 1.)—Flowers in whorled spikes. Leaves spreading.—Native of the Cape of Good Hope, as indeed are all the remaining species. They flower from July to September. *Stem* upright, branched. *Leaves* spreading, small, lanceolate, crowded, recurved, gibbous at the base, hoary. *Flowers* in lengthened spikes, like a fox’s tail, pale red, interrupted. Scales of the calyx almost bristly.

2. *S. plumosum*. Feathered Seriphium. Linn. Sp. Pl. 1316. Mant. 481. (Stæbe plumosa; Willd. Sp. Pl. v. 3. 2407.)—Flowers about six in a whorl, spiked. Leaves clustered, awl-shaped.—Leaves thread-shaped, granulated. *Flowers* lateral, sessile, imbricated.

3. *S. fuscum*. Brown Seriphium. Linn. Sp. Pl. 1317. Mant. 481. (Stæbe fusca; Willd. Sp. Pl. v. 3. 2407.)—Flowers in terminal heads. Leaves linear, awnless, downy. *Stems* branched, wavy. *Leaves* ash-coloured. *Flowers* sessile, terminal, clustered.

4. *S. ambiguum*. Doubtful Seriphium. Linn. Syst. Veg. ed. 14. 799. (Artemisia ambigua; Linn. Sp. Pl. 1190. Willd. Sp. Pl. v. 3. 1815.)—Flowers about three together, spiked. Leaves linear. *Stem* shrubby, procumbent, branched, ash-coloured. *Leaves* simple, linear, clustered. *Flowers* in long, terminal spikes.

The seed-down of this species being feathered at the tip, induced Linnæus to make it a *Seriphium*.

**SERIPHUS**, or **SERPHUS**, in *Ancient Geography*, an island in the Archipelago, and one of the Cyclades, according

ording to Herodotus, the inhabitants of which took the part of the Greeks against Xerxes. Some authors, however, place Seriphus in the rank of the Sporades. It is situated west of Paros, and south of Cythnus. It presents the appearance of a rock, but is inhabited. The Romans sent thence certain criminals.

SERIPPO, a town of Hispania, in Bætica. Pliny.

SERI SOMTOU, in *Geography*, a district of Thibet, situated between E. long.  $95^{\circ}$  and  $96^{\circ}$ , and between N. lat.  $30^{\circ}$  and  $31^{\circ}$ .

SERISSA, in *Botany*, a genus of Jussieu's, and by that author correctly separated from *Lycium*. Loureiro calls it *Dyfoda*, from *δυσωδός*, *sinking*, because of its remarkably fetid smell.—Juss. Gen. 209. Willd. Sp. Pl. v. 1. 1061. Ait. Hort. Kew. v. 1. 376. Lamarck Illustr. t. 151. (*Dyfoda*; Loureir. Cochinch. 145. *Buchozia*; L'Herit. Monogr.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juss.

Gen. Ch. Cal. Perianth superior, divided into five, awl-shaped, erect segments. Cor. of one petal, funnel-shaped; tube short; limb broad, reflexed, five-cleft; segments trifid, acute. Stam. Filaments five, very short, below the mouth of the tube; anthers oblong, incumbent. Pist. Germen inferior, roundish; style thread-shaped, the length of the corolla; stigma oblong, villous, cloven, reflexed. Peric. Berry roundish, small, of one cell. Seeds numerous, (according to L'Heritier and Brown only two,) ovate, small.

Eff. Ch. Corolla funnel-shaped, fringed at the mouth. Segments of the limb mostly three-lobed. Berry inferior, with two seeds.

1. *S. fatida*. Japanese Seriffa. Willd. n. r. Ait. Hort. Kew. v. 1. 376. (*Lycium japonicum*; Curt. Mag. t. 361.)—Native of China and Japan, flowering throughout the summer.—Stem shrubby, much divided, about two feet high, erect. Branches ascending. Leaves sessile, oblong, ovate, entire, flat, small, clustered together. Flowers solitary or clustered, generally terminal, white.

This elegant little shrub produces numerous white flowers, which have the appearance of those of Jasmine, but are without scent, as indeed is the whole plant, until it be squeezed or bruised, when it emits a highly disgusting smell. A variety with double flowers is not uncommon in the gardens about London.

SERIUM, in *Ancient Geography*, a town of European Sarmatia, in the vicinity of the Borythenes. Ptolemy.

SERKA, in *Geography*, a town of Nubia; 200 miles S. of Sennaar.

SERKEISK, a town of Russia, in the government of Kaluga; 44 miles W.S.W. of Kaluga. N. lat.  $54^{\circ} 16'$ . E. long.  $34^{\circ} 34'$ .

SERKES. See TSEKESH.

SERKIS, a town of Asiatic Turkey, in Caramania; 50 miles W. of Cogni.

SERLIO, SEBASTIANO, in *Biography*, an eminent architect, was a native of Bologna, who flourished in the early part of the sixteenth century at Venice, in the character of an architect. He afterwards travelled through Italy, and resided a considerable time at Rome, where he studied the fine arts, and made many drawings of edifices, ancient and modern, and he is said to have been the first who examined, with the eye of a man of science, the remains of ancient architecture. The knowledge which he acquired was given to the public in a complete treatise of architecture, of which he planned several books, and the first that appeared was the fourth in order, comprehending the general rules of architecture, which he printed at Venice in

1537, dedicated to Hercules II. duke of Ferrara. The other six books appeared successively at different intervals, and the different editions made of them prove their popularity. Serlio, in 1541, was invited to France by Francis I. and was by that sovereign employed in the erections at Fontainebleau, where he thenceforth resided, and where he died, at an advanced age, in 1578. Though as an author he was much attached to the principles of Vitruvius in his designs as an artist, he very much neglected them. His school of St. Roch, and palace Grimani at Venice, are built in a grand and magnificent style. Gen. Biog.

SERMAISE, in *Geography*, a town of France, in the department of the Marne; 19 miles S. of Menehould.

SERMAISES, a town of France, in the department of the Loiret; 7 miles N. of Pithiviers.

SERMAKI, a town of Sweden, in the province of Tavastland; 170 miles N. of Tavasthus.

SERMANICOMAGUS, in *Ancient Geography*, a town of Gaul, which, according to the tables of Peutinger, was situated in Aquitania secunda. It was on the right of the Charente, at some distance N. of Iculisna, according to M. d'Anville; it is the present Chermes.

SERMATIA, in *Geography*, a town of Hindoostan, in the subah of Agra; 25 miles N.E. of Kerowly.

SERMATTA, an island in the East Indian sea, about 22 miles long, and six broad. S. lat.  $8^{\circ} 9'$ . E. long.  $129^{\circ} 13'$ .

SERMESOK, an island near the W. coast of Greenland. N. lat.  $61^{\circ} 50'$ . W. long.  $47^{\circ} 47'$ .

SERMIA, a river which rises near Montegio, in the state of Genoa, and after passing by Scerravalle, Tortona, &c. runs into the Tanaro.

SERMIN, a town of Iltria; 2 miles N.E. of Capo d'Iltria.

SERMIONE, a town and castle of Italy, in the Veronese, on a neck of land running into lake Garda, the harbour of which may be shut by means of chains, defended by a castle. This was the native place of the poet Catullus; 16 miles W. of Verona.

SERMOCINATION, SERMOCINATIO, in *Rhetoric*, denotes discourse in general, whether held by a person alone, or in company, and is the same with what is otherwise called dialogism.

SERMOLOGUS, SERMOLOGUE, an ecclesiastical book composed of sermons, or homilies of popes, and other persons of eminence and sanctity, formerly read at the feasts of the Confessors, the Purification, All Saints, and on every day from Christmas to the octave of the Epiphany. See HOMILY.

SERMON, a discourse delivered in public, for the purpose of religious instruction and improvement: or a persuasive oration.

As to the choice of subjects for a sermon, they should be such as in the judgment of the preacher seem to be the most useful, and the best accommodated to the circumstances of his audience. The unmeaning applause which the ignorant give to what is above their capacity, common sense and common probity must teach every man to despise. Usefulness and true eloquence are inseparable, nor can any man be justly deemed a good preacher, who is not an useful one. In a sermon, considered as a peculiar species of composition, the first object of attention is its unity; by which we mean, that there should be some one main point, to which the whole train of a sermon should refer. This unity, however, does not require that there should be no separate heads or divisions in the discourse, or that one thought should again and again be presented to the hearer in different lights. Separate divisions or distinct heads, provided that they are not too numerous

## SERMON.

numerous and too minute, serve to aid the composer and the hearer of a sermon. In order to render sermons more striking, and consequently more useful, the subject of them should be precise and particular. General subjects, though often chosen by young preachers, because they offer a more ample supply of matter, without much labour of thought, and a wider scope for the display of showy talents, are by no means the most favourable for producing the high effects of preaching. These subjects, often recurred to, admit of little diversity and variety. The attention of the hearer is more certainly engaged and fixed, by seizing some particular view of a great subject, some single interesting topic, and directing to that point the whole force of argument and eloquence. Here indeed the execution is more difficult, but the merit and the effect are higher. Moreover, the composer of a sermon should never study to say all that can be said upon a subject: no error can be greater than this. On the other hand, the preacher should select the most useful, striking, and persuasive topics which the text suggests; and with this view he should consider, that discourses for the pulpit are intended less for information than persuasion, and that nothing is more opposite to persuasion than an unnecessary and tedious fulness. Again, in studying a sermon, the preacher ought to place himself in the situation of a serious hearer; and derive his principal materials from those views of a subject, and those arguments and reflections which would operate most favourably and most effectually on his own mind. Above all things, the preacher should study to render his instructions interesting to the hearers. In this respect, much depends on the delivery of a discourse, but much will also depend on the composition of it. Correct language and elegant description are but the secondary instruments of preaching in an interesting manner. The great secret lies, in bringing home all that is said to the hearts of the hearers, so that every man may be led to think that the preacher is addressing him in particular. It is hardly necessary to subjoin a caution here, that personality should be avoided. For the attainment of the end now alluded to, the preacher should avoid all intricate reasonings, and expressing himself in general speculative propositions, or laying down practical truths in an abstract metaphysical manner. As much as possible, the discourse ought to be carried on in the strain of direct address to the audience; not in the strain of one writing an essay, but of one speaking to a multitude, and studying to mix what is called application, or what has an immediate reference to practice, with the doctrinal and didactic parts of the sermon. In this connection we may add, that the preacher should adapt his discourses, with a view of making them interesting, to the different ages, characters, and conditions of men, and that he should avail himself of any personal or domestic occurrence, for imparting either instruction or consolation. Some of the most impressive discourses are those that delineate and exhibit examples founded on historical facts, and drawn from real life. Many of these may be found in scripture, which, when they are well chosen, command a high degree of attention. Bishop Butler's sermon on the "character of Balaam," affords a specimen of this kind of preaching. It is of importance to observe, farther, that the preacher should be cautious not to take his model from particular fashions that chance to have the vogue. It is the universal taste of mankind, which is subject to no changing modes, that alone is entitled to possess any authority: and this will never give its sanction to any strain of preaching that is not founded in human nature, connected with usefulness, adapted to the proper idea of a sermon, as a serious persuasive oration, delivered to a multitude, in order to make them better men. Let the preacher form himself upon this

standard, and he will attain reputation and success much more than by a servile compliance with any popular taste, or transient humour of his hearers.

As to the style of sermons, it should in the first place be very perspicuous. Plainness and simplicity should prevail; and of course all unusual, swollen, or high-sounding words should be avoided; and especially those that are merely poetical, or merely philosophical. Dignity of expression is indeed indispensable; but this dignity is perfectly consistent with simplicity, and also with a lively and animated style, dictated by the earnestness which a preacher ought really to feel, and not merely to affect, and justified by the grandeur and importance of his subjects. He not only may employ metaphors and comparisons, but, on proper occasions, may apostrophise the saint or the sinner, may personify inanimate objects, break out into bold exclamations, and, in general, command the most passionate figures of speech.

The language of scripture, properly employed, is a great ornament to sermons; and it may be employed either in the way of quotation or allusion. But the allusions which the preacher uses should be natural and easy, for if they seem forced, they approach to the nature of conceits. In a sermon, no points or conceits should appear, no affected smartness and quaintness of expression; which derogate much from the dignity of the pulpit. It is a strong expressive style, rather than a sparkling one, that ought to be studied. Epithets have often great beauty and force, but it is a great error to imagine, that we render style strong and expressive, by a constant and multiplied use of epithets.

As to the question, whether it be most proper to write sermons fully, and commit them accurately to memory, or to study only the matter and thoughts, and trust the expression, in part at least, to the delivery, Dr. Blair is of opinion that no universal rule can be given. Preachers must adopt either of these methods, according to their different genius, and we may add according to the situation where they are settled, and the rank or character of the assembly which they address. It is proper, however, to begin, at least, the practice of preaching, with writing as accurately as possible. He thinks it also proper to continue, as long as the habits of industry last, in the practice both of writing and committing to memory. The practice of reading sermons is, as our author says, one of the greatest obstacles to the eloquence of the pulpit in Great Britain, where alone this practice prevails. No discourse which is designed to be persuasive can have the same force when read as when spoken. We are of opinion, however, that sermons from memory have little advantage, in point of effect, above those that are read. An extemporary sermon has this advantage in an eminent degree; but few excel, and many discourses of this kind are such as would disgust a judicious, though candid, hearer.

The French and English writers of sermons proceed upon very different ideas of the eloquence of the pulpit. A French sermon is, for the most part, a warm animated exhortation; an English one, a piece of cool instructive reasoning. The French preachers address themselves chiefly to the imagination and the passions: the English, almost solely to the understanding. The union of these two kinds of composition, of the French earnestness and warmth with the English accuracy and reasoning, would form, in Dr. Blair's judgment, the model of a perfect sermon. The censure which, in fact, the French critics pass on the English preachers is, that they are philosophers and logicians, but not orators. Among the French Protestant divines, Saurin is the most distinguished; and the late Mr. Robinson of Cambridge has done a public service by translating many of his discourses into the English language.

Saurin is copious, eloquent, and devout, though, in his manner, too ostentatious. Among the Roman Catholics, the two most eminent are Bourdaloue and Massillon. The French critics differ in their opinion to which of these preachers the preference is due. To Bourdaloue they attribute more solidity and close reasoning; to Massillon, a more pleasing and engaging manner. The former is a great reasoner, and inculcates his doctrines with much zeal, piety, and earnestness; but his style is verbose, and abounding with quotations from the fathers, and he wants imagination. Massillon has more grace, more sentiment, and, as Dr. Blair thinks, may have more genius. He discovers much knowledge, both of the world and of the human heart; he is pathetic and persuasive, and is perhaps the most eloquent writer of sermons which modern times have produced. During the period that preceded the restoration of Charles II., the sermons of the English divines abounded with scholastic casuistical theology, but in their application they adopted more pathetic addresses to the consciences of the hearers. Upon the restoration, preaching assumed a more correct and polished form. Whatever was earnest and passionate, either in the composition or delivery of sermons, was reckoned enthusiastic and fanatical; and hence that argumentative manner, bordering on the dry and unperceptive, which is too generally the character of English sermons. Dr. Clark, who excels in a variety of respects, may be esteemed a very instructive composer of sermons, but he is deficient in the power of interesting and seizing the heart. Tillotson's manner is more free and warm, and he approaches nearer than most of the English divines to the character of popular speaking; and he is, even now, one of the best models for preaching. Dr. Barrow is admirable for the prodigious fecundity of his inventions, and the concurrence, strength, and force of his conceptions; but less happy in execution, or composition. Atterbury deserves to be particularly mentioned as a model of correct and beautiful style, besides having the merit of a warmer and more eloquent strain of writing in some of his sermons, than is commonly met with. If Buller had given us more sermons in the strain of those upon self-deceit and the character of Balaam, in the room of abstract philosophical essays, he might have been distinguished for that species of characteristical sermons above recommended.

The parts of a sermon, discourse, or regular formed oration, are the following six; *viz.* the exordium or introduction, the state and division of the subject, narration, and explication, reasoning, or arguments, the pathetic part, and the conclusion. (See each under its proper head.) The introduction of an English sermon is too often stiff and formal, whereas those of the French preachers are very splendid and lively. Common-place topics should be avoided: variety should be studied; and in some cases the discourse may commence without an introduction. Explanatory introductions from the context are not uncommon, they are appropriate and instructive; but they should not be too long. An historical introduction has, generally, a happy effect in causing attention. To the proposition or enunciation of the subject generally succeeds the division; but it has been questioned, whether this method of laying down heads, as it is called, be the best method of preaching. Archbishop Cambray declares strongly against it; alleging, that it is a modern invention, that it was never practised by the fathers of the church, and that it took its rise from the schoolmen. But we are of opinion, with Dr. Blair, that it serves useful purposes, and ought not to be laid aside. (See the preceding part of this article.) But in any discourse or sermon, there are certain rules which should be observed, *e. g.* the several parts into which the subject is divided should be really dis-

tinged from one another: the order of nature should be followed, beginning with the simplest points, or those that are most easily apprehended and necessary to be first discussed, and then proceeding to those which are built upon the former, and which suppose them to be known:—the several members of a division ought to exhaust the subject:—the terms in which the partitions are expressed should be as concise as possible:—and the number of heads should not be needlessly multiplied. Another part of a discourse or sermon is narration. This part must be concise, clear, and distinct, and in a style correct and elegant, rather than highly adorned. The argumentative part is succeeded by the pathetic, in which, if any where, eloquence reigns, and exerts its power. (See PATHETIC.) In sermons, inferences from what has been said make a common conclusion. With regard to these care should be taken, not only that they rise naturally, but that they should so much agree with the strain of sentiment throughout the discourse, as not to break the unity of the sermon. The precise time of concluding a discourse is an object of importance. It should be so adjusted that our discourse is brought to a point; neither ending abruptly and unexpectedly; nor disappointing the expectation of the hearers, when they look for the close; and continuing to hover round and round the conclusion, till they become heartily tired of us. We should endeavour to go off with a good grace; not to end with a languishing and drawing sentence; but to rise with dignity and spirit, that we may leave the minds of the hearers warm; and dismiss them with a favourable impression of the subject, and of the speaker. Blair's Lectures, vol. ii. See ELOCUTION of the Pulpit, and PREACHING.

SERMON, *Funeral*. See FUNERAL.

SERMONES, the title which Horace gives his Satires. See SATIRE.

Critics are divided about the reason of the name; the opinion of father Bosiu seems best grounded. A mere observance of feet and measure, such as we find in Terence, Plautus, and in Horace's Satires, he thinks is not sufficient to constitute verse, to determine the work to be poetical, or to distinguish it from prose; unless it have some farther air, or character of poetry; somewhat of the fable or the sublime.

Hence he judges it is, that Horace calls his Satires *prose*, or *sermons*: his Odes have quite another air, and are therefore called *poems, carmina*.

SERMONETTA, in *Geography*, a town of Italy, in the Campagna, situated on a mountain difficult of access. Some say that it occupies the site of the ancient Sora; but others say that it occupies the spot on which Sulmo stood; 13 miles S. of Veletri.

SERMONIUM, in *Old Records*, a kind of interlude or historical play, which the inferior orders of clergy, assisted by boys, &c. used at times to act in the body of the church, suitable to the solemnity of some festival or high procession day.

This is supposed to have been the origin of the modern drama.

SERMOUNTAIN, in *Botany*, a species of the laserwort in the Linnæan system, and, according to others, of the *seseli*, or wild spignel, which grows wild in some of the southern parts of Europe, is raised with us in gardens, and flowers in June.

The seeds of this plant are the part directed for use in our pharmacopœias, and the roots appear to be useful aromatics, though not regarded in practice; of an agreeable smell, and a warm glowing sweetish taste; the roots have the greatest warmth and pungency; the seeds the greatest sweetness, and the most pleasant flavour. A spirituous extract

tract of the feeds is a very elegant aromatic sweet. Lewis. See *SESELI Sæd.*

**SERMUR**, in *Geography*, a town of France, in the department of the Creuse; 6 miles S.S.W. of Anzance.

**SERNA**, LA, a town of Spain, in the province of Leon; 24 miles N. of Palencia.

**SERNANCHELLA**, a town of Portugal, in the province of Beira; 19 miles S.E. of Lamego.

**SERNETTY**, a town of Bengal; 30 miles E.S.E. of Calcutta.

**SERNICIUM**, in *Ancient Geography*, a town of Italy, on the route from Milan to Colonne, in passing through Picenum, according to the Itinerary of Antonine, in which it is marked between *Aufidena Civit.*, and *Bovianum Civit.*

**SERNON**, in *Geography*, a town of France, in the department of the Var; 7 miles N.W. of Grasse.

**SERNST**, a town of Switzerland, in the canton of Glaris, near a river of the same name; 3 miles S. of Glaris. The river runs into the Sundbach at this place.

**SEROGLAZOVSKAIA**, a fortress of Russia, in the government of Caucasus, on the Volga; 24 miles N.W. of Atrachan.

**SEROLZECK**, a town of the duchy of Warsaw, at the union of the rivers Narew and Bug; 20 miles N. of Warsaw.

**SERON**, a town of Spain, in the province of Grenada; 7 miles W. of Purchena.

**SERON** of *Almonds*, is the quantity of two hundred weight; of anise-seed, it is from three to four hundred; of Castile soap, from two hundred and a half to three hundred and three quarters.

**SERONGE**, in *Geography*, a town of Hindoostan, in the Malwa country, celebrated for its manufacture of printed cottons and chintzes; 132 miles N.E. of Ougein. N. lat.  $24^{\circ} 5'$ . E. long.  $78^{\circ} 4'$ .

**SEROOR**, a town of Hindoostan, in Dowlatabad; 24 miles S.S.W. of Amednagar.

**SEROS**, LOS, a town of the island of Cuba; 38 miles N. of Trinidad.

**SEROSITY**, the watery part of the blood, or *serum*. See *BLOOD*.

**SEROTA**, in *Ancient Geography*, a town of Pannonia, between Lentuli and Mariniæ.

**SEROUGE**, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 80 miles S.W. of Diarbekir.

**SEROWRA**, a town of Hindoostan, in Oude; 4 miles N. of Lucknow.

**SERPA**, a town on the E. coast of the island of Corfu; 8 miles N. of Corfu.—Also, a town of Portugal, in Alentejo, containing two churches, and about 4000 inhabitants; 12 miles S.W. of Mourao.

**SERPA**, in *Ancient Geography*, a town of Hispania, in Bætica, on the left of the river Anas, and nearly E. of Pax-Julia.

**SERPEGER**, in the *Manege*, was used to denote the riding a horse in the serpentine way, or in a tread with waved turnings like the posture of a serpent's body; but is now become obsolete.

**SERPENTARA**, in *Geography*, a small island near the E. coast of Sardinia. N. lat.  $39^{\circ} 18'$ . E. long.  $10^{\circ} 2'$ .

**SERPENTARIA**, in *Botany*, a name applied by the older botanical and medical writers, to various plants, either on account of the serpent-like form of their roots, as in *Polygonum Biflorum*, their spotted stems, as in *Arum Dracunculus*, or some other fanciful resemblance. The same name has likewise been given to plants supposed to cure the

bites of serpents, as *Aristolochia Serpentaria*, or Virginian Snake-root. For a similar reason certain species of *Plantago* have been denominated *Serpentina*.

**SERPENTARIUS**, in *Astronomy*, a constellation of the northern hemisphere, called also *Ophiuchus*, and anciently *Æsculapius*.

The stars in the constellation Serpentarius, in Ptolemy's catalogue are 29; in Tycho's, 15; in Hevelius's, 40; in the Britannic catalogue, they are 74. See *CONSTELLATION*.

**SERPENTES**, **SERPENTS**, in *Zoology*, the second order in the Linnæan class Amphibia, which are thus commonly characterized: they are footless; their eggs are connected in a chain; the penis is double, and mucicate.

These animals are sufficiently distinguished from reptiles by their total want of feet, moving by the assistance of their scales, and their general powers of contortion. The distinction of species in this numerous tribe is, according to Dr. Shaw, frequently very difficult. Linnæus thought that an infallible criterion might be found in the number of scaly plates on the abdomen, and beneath the tail; and accordingly attempted, in the *Systema Naturæ*, to discriminate the species by this mark alone. This is now found to be, by much, too uncertain and variable for a specific test. The colour is indeed frequently variable, but the pattern, or general distribution of markings in each species, appears to be more constant; the relative size of the head, the length of the body and tail, the size, smoothness, or roughness of the scales, as well as their shape in different parts of the animal, often afford tolerably certain specific marks.

The distinction of serpents into poisonous and innocuous, can only be known by an accurate examination of their teeth; the fangs, or poisoning teeth, being always of a tubular structure, and calculated for the conveyance or injection of the poisonous fluid from a peculiar reservoir, communicating with the fang on each side of the head; the fangs are always situated in the anterior and exterior part of the upper jaw, and are generally, but not always, of much larger size than the other teeth; they are also frequently accompanied by some smaller or subsidiary fangs, apparently destined to supply the principal ones, when lost either by age or accident. The fangs are situated in a peculiar bone, so articulated with the rest of the jaw, as to elevate or depress them at the pleasure of the animal. In a quiescent state, they are recumbent, with their points directed inwards or backwards; but when the animal is inclined to use them as weapons of offence, their position is altered by the peculiar mechanism of the above-mentioned bone, in which they are rooted, and they become almost perpendicular.

A general rule for the determination of the existence or non-existence of these organs, in any species of serpent, was proposed by Dr. Gray, in the *Transactions of the Royal Society* for the year 1788. According to this author, the fangs may be distinguished with great ease, by the following simple method. When it is discovered that there is something like teeth in the anterior and exterior part of the upper jaw, which situation he considers as the only one in which venomous fangs are ever found, let a pin, or other hard body, be drawn from that part of the jaw to the angle of the mouth. If no more teeth be felt in that line, it may be fairly concluded that those first discovered are fangs, and that the serpent consequently is venomous: if, on the contrary, the teeth first discovered be observed not to stand alone, but to be only part of a complete row, it may as certainly be concluded that the serpent is not venomous. This rule, however, like most other general rules, may have its exceptions; and perhaps the most legitimate test of real fangs

fangs in a serpent is their tubular structure, which may always be easily detected by the assistance of a proper magnifier. It is to be observed, that all serpents, whether poisonous or not, have, besides the teeth, whether fangs or simple teeth, in the sides of the upper jaw, two additional or interior rows, which are generally much smaller than the rest, and frequently scarcely visible. The general rule, therefore, is, that all venomous serpents have only two rows of true or proper teeth in the upper jaw, and that all others have four.

A head entirely covered with small scales is, in some degree, a character, but by no means an universal one, of poisonous serpents; as are also carinated scales on the head and body, or such as are furnished with a prominent middle line. All serpents cast their skins at certain periods: in the temperate regions, annually; in the warmer climates, perhaps more frequently. The serpents of the temperate and cold climate also conceal themselves, during winter, in cavities beneath the surface of the ground, or in some other convenient places of retirement, and pass the winter in a state more or less approaching, in the different species, to complete torpidity. Some serpents are viviparous, as the rattle-snake, the viper, and many other of the poisonous kind; while the common snake, and probably the greater part of the innoxious serpents, are oviparous, depositing, as we have already observed, their eggs, in a kind of string or chain, in any warm and close situation, where they are afterwards hatched. The broad undivided laminae, or scaly plates, on the bellies of serpents, are termed scuta; and the smaller or divided plates, beneath the tail, are called sub-caudal scales; and from these different kinds of laminae, the Linnæan genera of serpents are chiefly instituted. In the edition of the *Systema Naturæ* by Gmelin, seven genera are enumerated and described, *viz.*

Acrochordus,	Cæcilia,
Amphibæna,	Coluber,
Anguis,	Crotalus.
Boa,	

Having, in our alphabetical arrangement, omitted a description of some of the above genera, and referred to the species of others which have not yet been given, we shall take the opportunity which the order itself gives us, of making up for the defects that have escaped our notice, beginning with

**ACROCHORDUS**, of which the generic character is, that it has tubercles covering the whole body. Gmelin gives but a single species, *viz.* the javanicus; but Dr. Shaw has described three

#### Species.

**JAVANICUS**; or Warty Snake. Brown, beneath paler; the sides obscurely variegated with whitish.

This, as its specific name denotes, inhabits Java, chiefly among the pepper plantations; it grows sometimes to the length of seven or eight feet. The warts or prominences appear, by a magnifying glass, to be convex carinate scales, and the smaller ones are furnished with two smaller prominences, one on each side the larger. The head is somewhat flattened, hardly wider than the neck; the body is gradually thicker towards the middle, and suddenly contracting near the tail, which is short and slightly acuminate.

This remarkable snake, which gave rise to the institution of the genus, was first described by Mr. Hornsted, in the Swedish Transactions for the year 1787. It was found in a large pepper-ground near Sangasan, in the year 1784, and measured eight feet in length. Its neck was six inches thick, that of the largest part of the body ten inches, and that of

the tail an inch and a half; the colour of the upper part of the animal was blackish, and of the under part whitish; the sides are marked with dusky spots; the head is truncated, depressed, and scaly; the jaws equal, the superior being emarginated beneath, the inferior curved; the eyes lateral, on the fore part of the head, the irides livid; the nostrils circular, small, approximated, and situated above the tip of the snout; the body was entirely covered, as well as the tail, with rough tri-carinated warts; the vent is small, the body very suddenly tapering towards the tail. This animal was secured by a Chinese, by means of a split bamboo passed over its neck, and thus carried to Batavia, where, on being skinned and opened, exclusive of a quantity of undigested fruit, were found completely formed five young, measuring nine inches each; the flesh of the animal was eaten by the Chinese, who affirmed that it was excellent food, and the skin being preserved in spirits, was brought over to Europe by Mr. Hornsted, and deposited in the museum of the king of Sweden.

**DUBIUS**, or Brown Acrochordus, has a carinated abdomen, and its sides are spotted with black. In its general appearance and proportion, this very nearly resembles the javanicus just described; but the head of the dubius is covered with very minute rough or warty scales, differing in size alone from those on other parts of the animal. It is not more than about three feet in length; its colour is of an obscure brown, with some ill-defined clouds and patches of a darker colour, dispersed along the sides and abdomen. The specimen from which this description is taken, is in the British Museum; but its native place is not ascertained.

**FASCIATUS**, or Fuliginous Acrochordus, called also the *Hydrus granulatus*, has a carinated abdomen, with whitish ascendant lateral bands. This is so much allied to the dubius, that it may be doubted whether it really differs in any other respect than age, size, and in the cast of colours, measuring about eighteen inches in length, and being of a dusky brown colour, with several paler fasciæ, which take their rise from the abdomen, and ascend on the sides; the abdomen is carinated as in the former. "This," says Dr. Shaw, "is certainly the *Hydrus granulatus* of Mr. Schneider, who, in his work on the Amphibia, describes it as a water-snake, though, seemingly, without any other foundation than its having a carinated abdomen; its other characters by no means agreeing with those of the genuine *Hydri*." Its native place is not known. A specimen is preserved in the British Museum.

**ANGUIS**, or Snake. This genus of serpents was noticed in its place, and the names of the species enumerated, with the intention of describing each species in the alphabetical order: after this the plan of the work was somewhat altered, and the species will now be given with their appropriate description. The generic character is, scales on the belly and scales under the tail.

#### Species.

**STRIATUS**. The scales of the belly are 179 in number; those of the tail seven; the body is surrounded with transverse lines.

**MELEAGRIS**. The scales on the belly of this are 165; those of the tail 32. It inhabits South America and some parts of India. It resembles the *Lacerta bipes* (see *LIZARD*); it is glaucous, with numerous longitudinal rows of black dots. There are two varieties, one dotted with brown, and one characterized by its long tail.

**COLUBRINUS**. Scales of the belly 180; of the tail 18. It inhabits Egypt: is varied with brown and pale ochre.

**MILIARIS**. Scales of the belly 170; of the tail 32.

Found

## SERPENTES.

Found near the Caspian sea: it is 14 inches long, and is about as thick as one's finger; black, with numerous pale scales or dots on the sides, and grey ones on the back; the head is grey, sprinkled with black; the tail is two inches long, much thinner than the body, cylindrical, obtuse, varied with white.

**JACULUS.** The scales of the belly of this species are 186, those of the tail 23; it inhabits Egypt.

**MACULATUS.** There are on this 200 abdominal scales; 12 subcaudal ones. It inhabits America; above it is yellow, with a brown dorsal stripe and linear bands. A variety is deflated with red bands dotted with black. It inhabits Asia.

**RETICULATA.** Scales on the belly 177; of the tail 37. This is an American snake. The scales are brown with a white disk.

**CRASTES.** Abdominal scales 200; subcaudal 15. It is found in Egypt.

**NASUTUS.** On the belly of this are 218 scales; on the tail 22. It is about a foot long; the colour is of a greenish-black; beneath, at the sides, on the tip of the head, a broad band on the tail, and dots on the tip, all yellow. The snout is prominent; it has no teeth; the eyes are on the top of the head, not lateral; the trunk is surrounded with 20 rows of hexagonal scales; the tail not quite half an inch long, with minute scales, and obtuse, rigid at the tip.

**LUMBRICALIS.** In this the scales of the belly are 230; those of the tail seven; it inhabits America. In colour it is whitish, inclining to yellow.

**LATICAUDA.** The abdominal scales are 200; the subcaudal 50. This is found at Surinam; the tail is compressed, sharp, pale, with brown bands.

**SCYTALE.** Scales of the belly 240; of the tail 13. As Dr. Shaw calls all the species of this genus by the English name flow-worm, so he denominates this the painted flow-worm, from its singular beauty; its general length is from eighteen inches to two feet, and its diameter in proportion; the ground colour is a rich yellowish-ferruginous or orange, on which are disposed throughout the whole length of the animal, numerous, moderately broad, equidistant, jet-black transverse bands, not continued entirely round the body, but alternating with each other, and terminating in rounded extremities; the scales on the intermediate parts are generally tipped with brown, exhibiting more or less of a speckled appearance on the skin. When this animal has been preserved a considerable length of time in spirits, many of its fine colours fade into white, in consequence of which, the specimens usually seen in museums, appear variegated only with black and white; the head is small, and the tail is very short, being not more than the twentieth of the whole length, and terminating obtusely. This species is a native of South America, and some of the West Indian islands.

\* **ERYX;** Aberdeen Snake. The scales on this species of the belly are 126; those on the tail 136. It inhabits America and England. Above it is cinereous, with black lines the whole length, beneath it is lead-colour, with white spots. It has been thought to be only a variety of the next species.

\* **FRAGILIS;** Blind Worm. Scales of the belly 135, and the same number on the tail. This species is found in almost all parts of Europe, in our own islands, and in Siberia, in similar situations with the common snake. It is a perfectly innoxious animal, living on worms and insects; its usual length is from ten to twelve inches, and sometimes even more; its colour is pale rufous-brown above, with three narrow longitudinal dorsal streaks of a darker cast; and beneath a deep lead-colour. The head is rather small, and

covered in front with large scales, as in most other innoxious serpents; the eyes are very small; the tail measures more than half the length of the animal, and terminates rather suddenly in a slightly acuminate tip. It is a viviparous animal, and sometimes produces a very numerous offspring; like other serpents, it varies in the intensity of its colours at different periods, and the young are commonly of a deeper cast than the parent; the general motions of this animal are rather slow than otherwise, except when endeavouring to escape, and the young seem to move more slowly than those that are full-grown. Slow-worms can, however, exert a considerable degree of swiftness, and can readily penetrate the loose soil, in order to conceal themselves from pursuit; they are often found in considerable numbers, during the winter season, at some depth beneath the surface, retiring on the approach of winter, and lying in a state of torpidity, and again emerging from their concealments on the approach of spring, when they cast their skin and recover their former liveliness. It has been observed by some naturalists, that if the individuals of this species, and of some others likewise, be struck with any degree of violence, the body not only breaks abruptly on the struck part, but even frequently at different parts; the skin is remarkably strong, and the animal, when handled or irritated, has a mode of stiffening itself by stretching to its utmost length, in which state, if any part of the skin be injured, the separation soon takes place in consequence of this rigidity. The fragments will live a long time after their separation.

**VENTRALIS.** Abdominal scales 127; subcaudal 223. This is an inhabitant of South Carolina. The body is of an ashy-green, striate: lateral band black; belly short, and appearing as if annexed by a hollow future; the tail is verticillate, three times as long as the body. A small blow will cause the animal to break into several pieces, the muscles being articulated quite through the vertebrae.

**PLATURUS.** Tail compressed, obtuse. It is a native of the shores of Pine island, in the Pacific ocean. The body is a foot and a half long; above it is black, and beneath it is white; the scales are minute, sub-orbicular, not imbricate; head oblong; it is toothless, smoothish; the back is subcarinate; the tail is variegated with black and white.

**LINEATUS.** Blackish, but on the upper part it is white: a curved line runs down the whole body.

**CLIVICUS.** Cinereous-brown; the plate of the front is larger and heart-shaped. It is found in some parts of Germany.

**ANNULATUS.** White, with straight brown bands meeting beneath, tail tapering, beneath with a double row of imbricate scales.

**SCUTATUS.** This is a very slender species; waved with white and black bands; plates of the head broad; tail sharpish. This is found at Surinam. The belly and tail beneath with transverse broad scales, like the boa. Gmelin thinks it does not belong to this species.

**CORALLINUS.** This is named by Shaw the pale-red flow-worm, with blood-red variegations, and by Seba it is called the red Brazilian serpent, so named probably from its colour, it being red with paler bands; the scales are tipped with black. This is a very elegant species; it is about a foot and a half long, the thickness is very considerable; the ground-colour is of a pale-red, with very broad, alternating fasciae, and variegations of a deep coral red; the scales are moderately large, and of a rounded form, and the head and tail are remarkably obtuse. This highly beautiful animal is a native of the warmer parts of South America, where it is said to be found in woods, and to derive its sustenance from the larger

## SERPENTES.

larger insects, as *Icolopendræ*, &c.; in colour it sometimes varies, a mixture of black in different proportions being blended with the red on the sides, and the bands are also more numerous in some specimens than in others.

**ATER.** This, as its name denotes, is black with white bands; scales tipped with black. This is nearly allied in general appearance to the *corallinus*, but differing in colour; being white with black bands; the abdominal scales are dilated according to Seba's figure, on the authority of which, a beautiful engraving of it is given by Shaw. It is a native of South America.

**RUFUS.** Tawny, with transverse but interrupted white lines; beneath it is variegated. This is found at Surinam.

**HEPATICUS.** Line on the top of the back, and a waved line on each side, of liver-colour, the spaces between paler, with roundish whitish spots. It inhabits Surinam.

**TESSELLATUS.** This species is of a saffron colour, with numerous bands, and three stripes: the head is white, and spotted with brown. It inhabits Paraguay.

**ALBUS.** The individuals of this species are entirely white; tapering towards each end.

**BOA**, another genus of the serpent race, has been generally described in the alphabetical arrangement, with references to the species, which having been neglected in their places, must be noticed now. (See *BOA*.) The genus, according to Gmelin, includes ten species, but Shaw mentions others; we shall first mention those given by Gmelin.

### Species.

**CONTORTRIX;** Hog-nosed Boa. The plates of the belly are 150 in number, and those on the tail 40. It inhabits Carolina; it is broad, and its back is convex; it is cinereous, with lateral round spots; it has a poisonous bag, but no fangs; the tail is about half the length of the body.

**CANINA.** This species has 203 plates on the belly, and 77 on the tail. It inhabits America. By Shaw it is named the Green Boa, with transverse, undulated, white dorsal bands. It is a highly beautiful snake, measuring, when full-grown, about four feet in length, and of a proportionable thickness; the head is large, and shaped like that of a dog; the colour of the whole animal on the upper parts is a most beautiful Saxon green, with several short, undulating, transverse white bars down the back, the edges of which are of a deeper or stronger green than the ground-colour of the body; the under or abdominal part is white. There is a specimen of this species in the British Museum.

A variety of this species is described by Seba; the ground-colour is of a bright orange, the dorsal bands are of a pale yellow, edged with red, and the abdomen is of a pale yellow. It is a native of the East Indies, differing merely in colour from the former.

**HIPNALE.** The plates on the belly are 179; those on the tail 120. It is found at Siam, and is of a yellowish colour, with white ocellate spots on the back.

**CONSTRUCTOR.** This, by some naturalists, is denominated the yellowish-grey boa, with a large chestnut-coloured chain-like pattern down the back, and subtriangular spots on the sides. Dr. Shaw gives the generic character thus: scuta, or undivided plates, both on the abdomen and beneath the tail. But by Gmelin it is characterized simply by the 240 plates on the belly, and 60 on the tail.

Of all the boæ, the most conspicuous is the *B. constructor*, which is at once pre-eminent, from superiority of size, and beauty of colours; in this respect it appears to be subject to considerable variation from age, sex, and climate, but may be distinguished in every state from the rest of its tribe

by the peculiar pattern or disposition of its variegations. The ground-colour of the whole animal in the younger specimens is a yellowish-grey, and sometimes even a bright yellow; on which is disposed along the whole length of the back, a series of large, chain-like, reddish-brown, and sometimes perfectly red variegations, leaving large, open, oval spaces of the ground-colour at regular intervals: the largest or principal marks composing the chain-like pattern above-mentioned are of a squarish form, accompanied on their exterior sides by large triangular spots, with their points directed downwards; between these larger marks are disposed many smaller ones of uncertain forms, and more or less numerous in different parts: the ground-colour itself is also scattered over by a great many small specks of the same colour with the variegations; the exterior edges of all the larger spots and markings are commonly blackish, or of a much deeper cast than the middle part, and the ground-colour immediately accompanying the outward edges of the spots is, on the contrary, lighter than on other parts, or even whitish, thus constituting a general richness of pattern, of which nothing but an actual view of a highly-coloured specimen of the animal itself can convey a complete idea. In the larger specimens, the yellow tinge is often lost in an uniform grey cast, and the red tinge of the variegations sinks into a deep chestnut; and in some the general regularity of the pattern before described is disturbed by a kind of confluent appearance: the head is always marked above by a large longitudinal dark band, and by a narrower lateral band passing across the eye towards the neck.

The *boa constrictor* is a native of Africa, India, the larger Indian islands, and South America, where it chiefly resides in the most retired situations in woody and marshy regions.

It was, in all probability, an enormous specimen of this very serpent that once diffused so violent a terror amongst the most valiant of mankind, and threw a whole Roman army into dismay. Historians relate this surprising event in terms of considerable luxuriance. Valerius Maximus mentions it from Livy, in one of the lost books of whose history it was related more at large, and the learned Frieshemius, in his *Supplementa Liviana*, has attempted a more ample and circumstantial narrative of the same event, of which the following is a quotation.

“ In the mean time *Regulus*, every where victorious, led his army into a region watered by the river *Bagrada*, near which an unlooked-for misfortune awaited them, and at once affected the Roman camp with considerable loss, and with apprehensions still more terrible; for a serpent of prodigious size attacked the soldiers who were sent for water, and while they were overwhelmed with terror, and unequal to the conflict, engulfed several of them in its enormous mouth, and killed others by writhing round them with its spires, and bruising them with the strokes of its tail: and some were even destroyed by the pestilential effluvia proceeding from its breath: it caused so much trouble to *Regulus*, that he found it necessary to contest the possession of the river with it, by employing the whole force of his army; during which a considerable number of soldiers were lost, while the serpent could neither be vanquished nor wounded; the strong armour of its scales easily repelling the force of all the weapons that were directed against it; upon which recourse was had to battering engines, with which the animal was attacked in the manner of a fortified tower, and was thus at length overpowered. Several discharges were made against it without success, till its back being broken by an immense stone, the formidable monster began to lose its powers, and was yet with difficulty destroyed; after having diffused such a horror

horror among the army, that they confessed they would rather attack Carthage itself than such another monster: nor could the camp continue any longer in the same station, but was obliged to fly; the water and the whole adjacent region being tainted with the pestiferous effluvia. A most mortifying humiliation to human pride! Here at least was an instance of a whole Roman army, under the command of Regulus, and universally victorious both by sea and land, opposed by a single snake, which conflicted with it when living, and even when dead obliged it to depart. The proconsul, therefore, thought it no diminution to his dignity to send the spoils of such an enemy to Rome, and to confess at once the greatness of his victory and his terror, by this public memorial: for he caused the skin of the snake to be taken off and sent to the city; which is said to have measured 120 feet: it was suspended in a temple, and remained till the time of the Numantine war."

**CENCHRIS**, the Rufescent Boa, with large dusky dorsal rings, and blackish kidney-shaped lateral spots with white centres; it has 265 plates on the belly, and 57 on the tail. It inhabits Surinam; it is greenish, with white ocellate spots; the irids are grey.

**OPHYRAS**, or Brown Boa, has on its belly 281 plates, on the tail 84; the body is brown, and in appearance it resembles the *B. constrictor*.

**ENYDRIS**; or Water Boa. This species is variegated with different shades of grey; the teeth in the lower jaw are longer than usual in this genus; the number of abdominal scuta is 270, and of those on the tail 105. It is very like the hortulana, hereafter to be described.

**MURINA**; Grey Boa. This species has 254 plates on the belly, and about 65 on the tail. It inhabits America. It is glaucous, with round black spots.

**SCYTALE**; Spotted Boa. Cinereous, with large orbicular black dorsal spots, and annulated lateral ones, with white centres; it has 250 plates on the belly, and 70 on the tail.

This is scarcely inferior in size to the *B. constrictor*, and is of similar manners, destroying, like that animal, goats, sheep, deer, &c.; it is generally of a grey or glaucous colour, marked with large orbicular black spots on the back, and with smaller ones of a similar form, but with centres, on the sides; while on the abdomen are scattered several oblong spots, and marks interspersed with smaller specks and variegations. It is a native of several parts of South America, and like other large snakes is occasionally eaten by the Indians.

**HORTULANA**; Garden Boa. This is of a yellowish-grey, with brown variegations, those on the head resembling lace; the body sub-compressed, and the sides marked by wedge-shaped spots; it has 290 plates of the belly, of the tail 128.

This very elegant serpent, which is of a moderate size, measuring only a few feet in length, and being of a slender form, has obtained its specific name from the singular variegations on the head, which represent the form of a parterre in an old-fashioned garden; the variegations on the body are, like those on the head, of a blackish-brown, on a pale ferruginous or yellowish ground; they are disposed into large circular, and sometimes angular patches on the sides, the centres of some being open, and of others marked by an oblong spot; besides these there are others interspersed of smaller size and of different forms; the abdomen is commonly yellowish, with dusky specks and patches; the ground-colour of the whole snake is sometimes of a pale violet, and the variegations of a dark purplish-brown; but in all its varieties this species may be easily distinguished by the rich

embroidered appearance of the pattern, and more particularly by that on the top of the head; the head is also broader, and the neck more slender in proportion, than in most of the other box, the body slightly compressed, and the tail slender. It is a native of South America.

Such are the Linnæan species given by Gmelin; the following are additional ones, described by Dr. Shaw in his *General Zoology*.

**REGIA**; Royal Boa. With longitudinal striped neck, and body variegated either with brown and grey, or orange and rose-colour. This species, which is described by Seba, is, in its general shape, most allied to the canina and the phrygia. It varies very much with respect to colour, the ground-work being white, but the variegations sometimes dusky or chestnut, and sometimes of an elegant orange-red, accompanied by a tinge of blossom-colour on the lighter parts of the pattern; the top of the head is filled by a large patch, from which run two long parallel stripes to a considerable distance on each side the neck, leaving a wider stripe of the ground-colour along the upper part, and which afterwards ceasing, forms a part of the general variegation, which consists of a large chain-like dorsal band running down on each side, at moderately distant intervals, into obtuse processes, or situations regularly bordered by the white ground-colour, the intervening lateral spaces being much lighter, and each is marked by a dusky patch on the upper part; the under parts of the body and tail are white, the head is covered in front with large scales, the tail is extremely short, and tapers rather suddenly.

**PHRYGIA**; Embroidered Boa. White, with a greyish cast on the back; the body is most elegantly marked with black lace-like variegations.

This is unquestionably one of the most elegant species of the whole serpent tribe; its variegations are so conducted, as to bear a striking resemblance to an embroidery in needlework. It is a native of the East Indies, where divine worship is paid to it.

**FASCIATA**; Fasciated Boa. With subtriangular body annulated with blue; is a native of India, and most generally found in the country of Bengal. It is of a yellow colour, marked with numerous dusky-blue transverse bands, continued at equal distances throughout the whole length of the animal, each band completely investing the body; the body is of a trigonal form, the sides sloping very considerably; along the ridge of the back runs a continued series of hexagonal scales. This snake is among the number of poisonous species, and its bite is considered by the Indians as fatal. A specimen was brought to Dr. Ruffel in the month of November 1788, in an apparently very weak and languid state. Being set at liberty, it shewed no disposition to bite; it suffered a chicken to get on its back, without noticing it; but the thigh of the bird being put within its jaws, it shewed immediate symptoms of having been poisoned, and it expired in the course of half an hour. This was the only experiment which was made, the snake dying the next day; but from the languid state in which it appeared, and the effect of its bite on the chicken, it may be concluded that, when in full vigour, it must be an animal of a highly dangerous nature.

**VIPERINA**; Viperine Boa. Grey, with a black, undulating, dorsal band, edged with white; and the sides spotted with black. It is about a foot and a half in length, and of a moderately brown colour. It is said to produce by its bite a slow wasting of the fingers and toes, similar to what happens in some leprous cases. A living specimen, however, was obtained in 1778, and though in good health, yet its bite was not followed by any deleterious effects.

**LINEATA**, Lineated Boa, called also Geedi Paragoodoo,

is of a slender form, with the general appearance of a coluber rather than a boa. It is of an extremely dark blue colour, so as to appear almost black in certain lights, and is marked throughout the whole length of the upper part by several transverse curved and dotted white lines at unequal distances, and varying in number in different individuals, from about 42 to 50: they are so disposed, as almost to represent for many large spotted circles. Dr. Shaw has given an account of some experiments on this animal, to whose work we refer our readers. See General Zoology, vol. iii. part ii.

**HORATTA.** This is of a dark brown, with a waving yellow band on each side, and a row of dorsal spots. This is one of the smaller species, measuring only about fifteen inches in length. The fangs, or poisoning organs of this snake, shew that it is noxious, but in what degree has never been ascertained; it is, however, said to be one of the most fatal.

**PALPEBROSA.** Whitish, obscurely fasciated with grey; with prominent eye-lids; this has 112 abdominal scuta, and 51 on the tail.

**ANNULATA.** Subferruginous, with black, orbicular, dorsal spots included in rings; reniform, ocellated, lateral spots, and abdomen undulated with dusky variegations. This is about two feet long, and in its general appearance it is allied to the *B. hortularia* and *enydris*. It is a native of South America.

**SERPENTS**, in *Astronomy*, a constellation in the northern hemisphere, called more particularly *Serpens Ophiuchi*. The stars in the constellation *Serpens*, in Ptolemy's catalogue, are 18; in Tycho's, 13; in Hevelius's, 22; and in the Britannic catalogue, 64. See **CONSTELLATION**.

**SERPENT Cucumber**, in *Botany*. See **TRICHOSANTHES**.

**SERPENS Hypnoticus**. See **HYPNOTICUS**.

**SERPENS Marinus**. See **SEA SNAKE**.

**SERPENS Rubescens**, the *red serpent-fish*, in *Ichthyology*, the name of a fish, properly of the *tænia* kind.

It resembles the common snake in figure, and is of a fine strong red in colour, and marked with oblique lines all down the sides, and long ones from the gills to the tail, one on each side; its mouth is but small, and its teeth sharp and ferrated; and it has all over its back a number of fine capillaments, set at distances from one another, even to the tail, and the same on the belly; its tail ends in a single fin.

**SERPENS Terrenus**, the *earth-serpent*, a name given by some of the chemical writers to nitre. It was originally given to the nitre of the ancients, a salt very different from that which we call nitre, but it has since been applied also to that salt.

**SERPENT-Stones**. See **SNAKE-Stones**.

**SERPENT'S-Tongue**, in *Botany*, a genus of the *cryptogamia filices* class; comprehending five species. See **ADDER'S-tongue**.

**SERPENTS' Tongues**. The island of Malta abounds with glossopetræ, or the petrified teeth of sharks, which, from their resemblance to a tongue, are by the vulgar supposed to be the tongues of serpents turned into stone by some miracle of St. Paul, when he was there. This island abounds not only with these, but with *buzonitæ*, and vast numbers of other remains of sea productions.

Augustino Scilla, who has written at large on the fossils of this island, gives a very rational account of their being the real remains of animals, which, according to his system, it is no way wonderful to find there.

In regard to the island of Malta, which so abounds with them at this time, he supposes that long since the time of the creation, and even without the assistance of the general

deluge, it may have been formed out of the sea, and that it appears plainly to have been at first no other than a mass of soft mud, with an immense number of sea-shells, teeth of fishes, and other remains of sea-animals mingled among it; and that these subsiding as low as they could among that thickening matter, have made the island what we now find it, that is, a heap of earth with these things in vast quantities buried in it, and at different depths. *Philos. Transf.* N<sup>o</sup> 219, p. 182.

And though there are found among these teeth, &c. in the island of Malta, great quantities of shells, of such species as are not natives of those seas, this is no objection to the opinion; since it is well known, that the winds, when violent, as they probably were about the time of the formation of that island, will bring such light bodies as shells a vast way in water.

The mountains of Sicily afford some few glossopetræ, or snakes' tongues, but they are few in number, and worse prepared than those of the island of Malta; which is probably owing to the high ground of those mountains being less likely to receive the refuse of the sea, and its soil, which is sandy, being less fitted to preserve them when there than the marle, of which the island of Malta consists.

The *echini marini*, or sea-eggs, and their species, which are very frequent among the serpents' tongues of Malta, all lie upon the surface of the ground, or near it; whereas the glossopetræ lie deeper, though at no great depth. This is a plain effect of all these things having been really animal bodies, and having floated in the mud, of which that island was formed; for in this it could not be otherwise, but that the glossopetræ, or serpents' tongues, being heavy, would subside in the water, while the light shells of these other animals would float on or near the surface.

Whenever the glossopetræ are taken carefully up out of the earth in Malta, the marle or earth, which served for their bed, is found to contain all their minutest traces and lineaments, like wax from a seal. This is a proof that the marle was as soft as melted wax when they were put into it, and that they were of the full size and growth when placed there, not having grown, or had any increase in that place.

The apophyses, or processes in the glossopetræ, are also a strong proof of their being no other than real sharks' teeth, since they exactly answer to those in the teeth of recent sharks, by which every tooth is received or inserted into its neighbour in the jaw. Nay, whereas sharks' teeth are mortified into one another in such a manner, that a man may easily tell which belongs to each side, which lie near the throat, and which near the front of the mouth; and whereas, in a shark's mouth, the teeth on the left side will not fit on the right, nor those above serve below, but that on seeing a recent tooth, a person of judgment will be able to say what part of the mouth it belonged to; so in the fossil sharks' teeth, or glossopetræ, there is not any one which may not be referred to the particular part of the mouth of the living animal, and could have belonged to no other. *Augustino Scilla, de Petrificac.* See **GLOSSOPETRA**.

**SERPENT**, in *Music*, a wind instrument of the bassoon kind, blown by a mouth-piece. It has its name from its serpentine figure; and is composed of two pieces of walnut-tree-wood, and covered with thin leather or shagreen.

This instrument has six holes, which give it a compass of twenty-seven notes. The mouth-piece is fixed in a socket of copper or silver. Its neck is curved, and its mouth-piece is of wood or ivory.

It is held in such a manner, as that the fore-finger, the middle-finger, and the ring-finger of the left hand, can stop the

the holes 1, 2, and 3; and the same fingers of the right hand, stop the holes 4, 5, and 6.

The abbé de Bœuf, in his History of Auxerre, tom. i. p. 643, says that, about the year 1590, Edmond Guillaume, a canon of Auxerre, found the means of boring and turning a cornet in the form of a serpent, which was used in concerts at his house, and the instrument having been perfected became common in the great churches. For the scale and compass of the serpent, see Laborde.

In France, the serpent used to be confined to the military bands; at present, says M. Laborde, it is confined to the church and processions. In cathedrals there is one on each side the choir.

Merfennus, who had studied this instrument, says, that if unfolded and straight, it would be more than six feet long. Laborde says eight feet. The compass of the instrument is now probably extended, which in the scale given in the folio Encyclopédie is from double B flat in the bass, to F in the first space of the treble.

Merfennus, who has particularly described this instrument, mentions some peculiar properties of it, *e. g.* that the sound of it is strong enough to drown twenty robust voices, being animated merely by the breath of a boy, and yet the sound of it may be attuned to the softness of the sweetest voice. Another peculiarity of this instrument is, that great as the distance between the third and fourth holes appears, yet, whether the third hole be open or shut, the difference is but a tone.

SERPENT, in *Mythology*, was a very common symbol of the sun, and he is represented biting his tail, and with his body formed into a circle, in order to indicate the ordinary course of this luminary; and under this form it was an emblem of time and eternity.

The serpent was also the symbol of medicine, and of the gods which presided over it, as of Apollo and Æsculapius: and this animal was the object of very ancient and general worship, under various appellations and characters. In most of the ancient rites we find some allusion to the serpent, under the several titles of Ob, Ops, Python, &c.

The idolatry is alluded to by Moses, Lev. xx. 27. The woman of Endor, who had a familiar spirit, is called *Oub*, or *Ob*, and it is interpreted Pythonissa: the place where she resided, says the learned Mr. Bryant, seems to have been named from the worship then instituted; for Endor is compounded of *En-ador*; and signifies *sons pitbonis*, the fountain of light, the oracle of the god Ador; which oracle was probably founded by the Canaanites, and had never been totally suppressed. His pillar was also called *Abbadir*, or *Abadir*, compounded of *ab* and *adir*, and meaning the serpent deity *Addir*, the same as *Adorus*.

In the orgies of Bacchus, the persons who partook of the ceremony, used to carry serpents in their hands, and with horrid screams call upon Eva! Eva!

Eva being, according to the writer just mentioned, the same as epha, or opha, which the Greeks rendered *ophis*, and by it denoted a serpent.

These ceremonies, and this symbolic worship, began among the Magi, who were the sons of Chus; and by them they were propagated in various parts. Wherever the Ammonians founded any places of worship, and introduced their rites, there was generally some story of a serpent. There was a legend about a serpent at Colchis, at Thebes, and at Delphi; and likewise in other places. The Greeks called Apollo himself *Python*, which is the same as *Oupis*, *Opis*, or *Oub*.

In Egypt there was a serpent named *Thermuthis*, which

was looked upon as very sacred; and the natives are said to have made use of it as a royal tiara, with which they ornamented the statues of Isis. The kings of Egypt wore high bonnets, terminating in a round hall, and surrounded with figures of asps; and the priests likewise had the representation of serpents upon their bonnets.

Abaddon, or Abaddon, mentioned in the Revelations. xx. 2. is supposed by Mr. Bryant to have been the name of the Ophite god, with whose worship the world had been so long infected. This worship began among the people of Chaldea, who built the city of Ophis upon the Tigris, and were greatly addicted to divination, and to the worship of the serpent. From Chaldea the worship passed into Egypt, where the *Serpent* deity was called *Canoph*, *Can-eph*, and *C'neph*; it also had the name of *Ob* or *Oub*, and was the same as the *Basiliscus*, or *royal Serpent*, the same as the *Thermuthis*, and made use of by way of ornament to the statues of their gods. The chief deity of Egypt is said to have been Vulcan, who was styled *Opas*; he was the same as *Ophis*, the *Sun*, and hence was often called *Ob-el*, or *Pytho sol*; and there were pillars sacred to him, with curious hieroglyphical inscriptions, bearing the same name, whence among the Greeks, who copied from the Egyptians, every thing gradually tapering to a point was styled *obelos*, or *obeliscus*.

As the worship of the serpent began among the sons of Chus, Mr. Bryant conjectures, that from thence they were denominated *Ethiopiens* and *Aithiopiens*, from *Ath-ope*, or *Ath-opes*, the god whom they worshipped, and not from their complexion: the Ethiopes brought these rites into Greece, and called the island where they first established them, *Ellopie*, *Solis Serpentis insula*, the same with *Eubœa*, or *Onbaia*, *i. e.* the *Serpent-island*.

The same learned writer discovers traces of the serpent worship among the Hyperboreans, at Rhodes, named Ophiusa, in Phrygia, and upon the Hellespont, in the island Cyprus, in Crete, among the Athenians, in the name of *Cecrops*, among the natives of Thebes in Bœotia, among the Lacedæmonians, in Italy, in Syria, &c. and in the names of many places, as well as the people where the Ophites settled. One of the most early heresies introduced into the Christian church was that of the Ophites. Bryant's Analysis of Ancient Myth. vol. i. p. 47, &c. p. 473, &c.

SERPENT *Islands*, in *Geography*, small islands near the N. coast of lake Huron. N. lat. 46° 2'. W. long. 82° 45'.

SERPENTS, *Island of*. See SZALGEN.

SERPENTINA, in *Botany*. See SERPENTARIA.

SERPENTINE, in *Chemistry*, a worm, or pipe of copper or pewter, twisted into a spiral, and ascending from the bottom of the alembic to the capital, and serving in the distillation of rectified spirit of wine.

SERPENTINE, in *Mineralogy*, a stone, which derives its name from the variety of its colours, supposed to resemble those of the serpent. The ancients called this stone *ophites*, from the Greek *οφις*, *serpent*, as being speckled like a serpent's skin. The most prevailing colour is green of different shades, spotted with red, or with dark green, and also clouded and veiny. Some serpentines are red, varying from a peach-bloom to a blood-red or scarlet. In rich variety of colours, this stone far exceeds any other of the great rock-formations. It will receive a high polish, and is nearly indestructible by fire or acids, and is therefore eminently suited for ornamental sculpture or architecture. The hardness of serpentine is variable: some kinds scarcely yield to the knife, others are easily worked. It is insubible by the blowpipe; the fracture is splintery, passing into small conchoidal;

## SERPENTINE.

choidal; the fragments are translucent at the edges; the lustre is somewhat resinous, and when powdered, it has an unctuous soapy feel. The specific gravity varies from about 2.6 to 2.7. Serpentine seems nearly allied to the mineral called *hornblende*, from which it differs in its constituent parts by containing more magnesia and less iron. Chrome has been found in some serpentines. The analysis of different serpentines shews a considerable variation in the proportion of their constituent parts,

from 45	to 29	Silex,
18	23	Alumine,
23	34	Magnesia,
3	4	Iron,
11	10	Water and loss.

Some serpentines contain 6 *per cent.* of lime.

The disciples of Werner divide serpentine into two species, the one called the noble serpentine, the other the common serpentine; the former they consider as older, and having a different geological position to the common serpentine; but for this distinction there does not appear sufficient reason, as the same beds will furnish specimens of both kinds. The noble serpentine has the richest variety of colours and the greatest degree of translucency. Serpentine, though not very rare in many alpine districts, is by no means so common as granite, slate, and limestone. Serpentine occurs in beds in gneiss and primary limestone, and in mica-slate: it also covers many rocks in amorphous masses, and may be observed graduating into chlorite or talc-slate. Serpentine has been remarked to exist generally at a low level in alpine districts; but there are some remarkable exceptions to this, particularly in the summits which surround the central parts of mount Rofa, in Switzerland. These summits have an elevation of more than 1700 fathoms, formed of beds of serpentine lying in a position generally horizontal.

Serpentine is more abundant in Europe, than any other part of the globe that has been yet explored. The whole front of the Alps facing Italy contains serpentine almost in every part, although there is very little in the side towards Switzerland. It extends through Italy, where it is called *gabbio*. One of the finest varieties is at the hills of *Impronetta*, near Florence: it contains much of that green, semitransparent, and fatty substance, which Saussure calls *smaragdite*, on account of its fine emerald-green colour. France has some mountains of serpentine, especially in *Limousin*.

The finest serpentines of Spain are from *Sierra Nevada*; two leagues from *Grenada*, they have a green base filled with glittering plates of a yellow colour. Superb columns have been made of it, which decorate the churches and palaces of *Madrid*. According to *Patrin*, serpentine is almost entirely wanting in northern Asia, with the exception of the eastern part of the *Ural mountains*, which separate Europe from Asia. There are some hills of serpentine, which at great intervals accompany their base, following their direction from north to south; there are also some detached branches which appear near *Tobolsk*, which is not far from these mountains. But from hence to the river *Amur*, a space of about three thousand miles, scarcely any vestiges are found either in the great chains of *Altai*, *Sayennes*, or the mountains of *Daouria*. The serpentines most known in Europe are those of *Saldbergh* in Sweden, and *Zeoblitz* in Saxony, from which vases of every kind are turned and exported to distant countries. The serpentine of *Bayreuth* is filled with garnets of the size of a pea, dispersed equally through the mass. When the stone is polished, they present a pleasing mixture of fine red spots

in a green base. Trinkets and other ornaments are made of it.

The mountain called *Roth Horn*, or *Red Horn*, which faces mount *Rofa* towards Italy, is elevated 1506 fathoms; it is composed of immense masses of serpentine of an irregular shape. The surface of this serpentine becomes a deep red by the action of the atmosphere, which oxygenates the iron it contains. It is this colour, and the elongated form, that have occasioned the mountain to be called *Red Horn*.

The serpentine of this mountain is covered by a *steatite* of a sea-green colour, mixed with carbonate of lime and grains of *felspar*. On this serpentine are laid beds of micaceous schist, intermixed with limestone, composed of more than one half of mica. These are again covered by serpentine: all the beds are nearly horizontal, rising a little towards mount *Rofa*.

Mount *Crevin*, another mountain near mount *Rofa*, is an inaccessible obelisk of a triangular form, which is elevated 2309 fathoms above the sea. It is composed of three distinct masses; the uppermost, which forms the summit, is of a yellow isabella colour. It is composed of serpentine mixed with micaceous schist, containing limestone and quartz. The middle is of gneiss and micaceous schist, and the lower one or base of the pyramid is serpentine; but the most remarkable hill of serpentine is in the chain of mountains that separates the *marggravate* of *Bayreuth* from the *Upper Palatinate*. Its elevation above the plain is about 300 feet; it extends in a direction from east to west. The rocks which crown the summit are of very pure serpentine, divided into beds, and resting on gneiss and hornblende. *M. Humboldt* having brought his compass near these rocks of serpentine, saw with surprise, that the north pole of the needle flew round to the south. He further observed, that the rocks on the northern and southern declivities have opposite poles. The eastern and western extremities of the hill do not exert any action on the magnetic needle, though the appearance of the stone is the same as on the north and south declivities. In the magnetic parts of the hill certain rocks are also observed, which are not magnetic in junction with similar rocks, that exert a strong action on the needle, some of them at the distance of 22 feet. The mountain not only exerts its action on the needle in its whole mass, like some other hills, it is manifest even in small fragments.

*Humboldt* observed, that minute fragments are briskly moved on presenting them to the point of a weak magnet; but they have not the least attraction for iron not magnetized. *Humboldt* convinced himself that this serpentine does not contain an atom of magnetic iron, all which it contains is in the state of oxyd. Its specific gravity is much less than that of other serpentines, scarcely reaching to 2000, that of common serpentine being upwards of 2700. This mountain of serpentine, taken in the aggregate, may be regarded as one large natural magnet, having two poles, the part equidistant from each displaying no signs of magnetic power, as is the case with small natural and artificial magnets. Like them too, if a fragment be broken from the mass, each small piece has its north and south pole, and a central part, which is not magnetic. That particular kind of soft serpentine, which is capable of being turned into vessels that resist the action of the fire, is called *pot-stone*, and has been already described. See *POT-STONE*.

*Steatite* and *amianthus*, a fibrous asbestos, are almost always associated with serpentine. (See *ASBESTUS* and *STEATITE*.) The finest amianthus occurs in *Corfica* forming

ing beautiful white silky threads of two or more feet in length, and is so abundant, that Dolomieu made use of it instead of flax to pack his minerals in when in that island.

Serpentine exists in various parts of the highlands of Scotland and the Hebrides; it is found both pure and alternating with mica-slate and limestone.

No well-characterized rocks of serpentine are known in South Britain, except in Cornwall and the Isle of Anglesea. The serpentine of Cornwall is not particularly distinguished for the beauty of its colours. Rocks of this mineral extend to the Lizard Point.

The most beautiful variety of serpentine in Great Britain, or perhaps in Europe, is that on the western side of Anglesea. It occurs at a low elevation associated with rocks of talcous slate. The beds are of considerable size, and divided by seams of asbestos. Some of the serpentine is intermixed with white crystalline limestone, like the verde antique from Italy; but the particles of white are generally smaller. Veins of quartz and feldspar, with brilliant laminae of schiller spar, also occur in some of the beds. It is sufficiently hard to resist the point of a copper tool, and takes a high polish. The colours are various shades of light and dark green and red, varying from a peach-bloom to a blood-red scarlet. The colours are intermixed and distributed in an infinite variety of spots and clouds, the effects of which are heightened by polishing.

Messrs. Bullock and Co. in Oxford-street, have established a manufacture of chimney-pieces, columns, and other ornamental articles of this stone, which has the advantage, being raised in vast blocks, to as to form columns and slabs in one piece, from 12 to 20 feet in length, and of proportionate diameter and breadth. A column of 12 feet in one shaft, composed of red serpentine, which we measured at Messrs. Bullock's manufactory, weighed two tons, and had no perceptible flaw or blemish in the whole piece. This is the most durable as well as the richest of British stones applied to ornamental sculpture, and is not exceeded in the variety or freshness of its colours by any of the costly marbles of Italy.

The Mona marble, as this serpentine is called by the proprietors, is not liable to have its colours injured by common fire, which is the case with many marbles, when made into chimney pieces; neither are the colours affected by acids, air, or moisture.

With such a valuable material for ornamental sculpture in our own island, it is greatly to be regretted, that such large sums should be annually paid to foreign nations in the purchase of stone for similar purposes, which is less durable and less beautiful. It would surely be more patriotic to encourage the proper application of the mineral treasures of our own country.

The stone called verde antique is a mixture of green serpentine with white granular limestone. See VERDE ANTIQUE.

SERPENTINE, in the *Manege*. A horse is said to have a serpentine tongue, if it is always frisking and moving, and sometimes passing over the bit, instead of keeping in the void space, called the liberty of the tongue.

The Romans, in breaking and dressing their horses, used to work them in *waving* or *serpentine* lines, as the practice is, or ought to be, at present. The French call this riding a horse *en serpentant*. The Greeks and Romans know it by the term of riding in *Mæanders*, in allusion to the windings and doublings of the celebrated river which bore that name.

SERPENTINE Column. See COLUMN.

SERPENTINE *Verfes*, are such as begin and end with the same word. As,

“Ambo florentes atatibus, Arcades ambo.”

SERPHERANT, in *Geography*, a village of Syria, supposed to be the ancient *Sarepta* (which see); 14 miles S.S.W. of Saide.

SERPHERO, the ancient *Seriphus*, an island in the Grecian Archipelago, about 36 miles in circumference. Its mountains are so rugged and steep that the poets feigned the natives to have been transformed into stone by Perseus. Here are mines of iron and loadstone. The inhabitants belong to the Greek church: they pay 800 crowns to the grand seignior, for the capitation and land-tax. The produce is but small. The onions are in high estimation. It was made a place of exile by the ancient Romans. N. lat. 37° 10'. E. long. 24° 34'.

SERPHERO *Poulo*, a small island, five miles N.E. of the former.

SERPI, *Grotta del*. See GROTTA.

SERPICULA, in *Botany*, derived from *serpo*, to creep, a name given by Linnæus to the present genus, in allusion to its creeping habit and diminutive stature.—Linn. Mant. 16. Schreb. 628. Willd. Sp. Pl. v. 4. 329. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 257. Pursh v. 1. 33. Juss. 318. Lamarek Illustr. t. 758. (*Laurembergia*; Berg. Cap. 350. Elodea; Michaux Boreal-Amer. v. 1. 20.)—Class and order, *Monocotyledon Tetrandria*. Nat. Ord. *Inundata*, Linn. *Onagra*, Juss.

Gen. Ch. Male, *Cal.* Perianth minute, four-toothed, erect, acute, permanent. *Cor.* Petals four, oblong, acute, sessile. *Stam.* Filaments four, very short; anthers oblong, about equal to the petals.

Female, on the same plant. *Cal.* Perianth superior, minute, in four deep permanent segments. *Cor.* Petals three, or none. *Pist.* Germen inferior, ovate, furrowed; style short; stigma obtuse. *Peric.* Nut cylindrical, furrowed, of one cell, deciduous. *Seed* one, or more, oblong.

Ess. Ch. Male, Calyx four-toothed. Petals four. Female, Calyx in four deep segments. Nut.

Obs. The second species differs widely from the original generic characters, being dioecious, with three-cleft flowers, and several seeds. The whole wants revision.

1. *S. repens*. Cape Serpicula. Linn. Mant. 124. Suppl. 416. Willd. n. 1. Ait. n. 1. (*Laurembergia repens*; Berg. Cap. 350. t. 5. f. 10.)—Leaves scattered, lanceolate, entire.—Native of the Cape of Good Hope. Sent to Kew, by Mr. Masson, in 1789. It is a perennial, herbaceous, greenhouse plant, flowering in July and August. *Stem* branched, leafy, creeping by fibrous radicles. *Leaves* acute, three-quarters of an inch long. *Flowers* axillary, two to four together; the males are described by Bergius and Linnæus as stalked.

2. *S. verticillata*. East Indian Serpicula. Linn. Suppl. 416. Willd. n. 2. Roxb. Coromand. v. 2. 33. t. 164.—Flowers three-cleft. Leaves whorled, finely serrated.—Native of clear standing sweet water in the East Indies, flowering during the cold season. This is dioecious. The male flowers are sessile, and without a tube, but the female ones have a long tube, and a sheath-like calyx. Both male and female are three-cleft. The seed-vessel seems an oblong capsule, with four seeds, one over another.

3. *S. veronicifolia*. Bourbon Serpicula. Willd. n. 3.—“Leaves opposite, ovate, toothed at the summit.”—Native of rocks in the isle of Bourbon. *Bory de St. Vincent*.—Stems creeping, slender, red. *Leaves* thickish, a line, or line and half,

half, long, resembling those of *Veronica agrestis*. Flowers monoecious, four-cleft, reddish, very minute.

4. *S. occidentalis*. American Serpicula. Pursh n. 1. (Elo-dea canadensis; Michaux Boreal-Amer. v. 1. 20.)—"Flowers united. Stigmas ligulate, cloven, reflexed. Leaves ternate, linear, acute."—Frequent in stagnant waters, from Canada to Virginia, flowering in July. Perennial. Flowers white, very small and delicate. Leaves when magnified very finely ferrulated. In the early part of the season they are, as Michaux describes, oblong and obtuse, but at the flowering time long, linear, and acute. Pursh.

SERPIGO, in *Medicine*, from *serpere*, to creep, is nearly synonymous with *herpes*, and signifies, in the language of the older writers, any spreading tetter, or excoriation of the skin. When the tetter is stationary, according to Forestus, it is called *impetigo*; but when it spreads and creeps from one place to another, it is called *serpigo*. (See Forest. Obs. Chirurg. lib. ii. obs. 11.) It is the property, however, of many eruptive diseases to spread in this manner, though very different in their nature from each other; whence in the more accurate nomenclature of the present day, the term *serpigo* is not used. It would be applicable, in fact, to diseases of every class, pustular, scaly, papular, and vesicular; to the diseases called impetigo, lepra, psoriasis, lichen, herpes, eczema, &c. It is, therefore, justly exploded.

SERPUCHOV, in *Geography*, a town of Russia, in the government of Moscow; 40 miles S. of Moscow. N. lat. 55°. E. long. 37° 2'.

SERPULA, in *Conchology*, a genus of the order Testacea, of which the generic character is, animal a terebella: shell univalve, tubular, and generally adhering to other substances; often separated internally by divisions at uncertain distances. There are about fifty species included in this genus, of which several are found in our own country.

#### Species.

NAUTILOIDES. Shell flattish, minute, confluent, verrucose, spiral, with very thin semilunar internal divisions. It is found in the seas about Norway, adhering to the *Madrepora prolifera*, is very minute, brownish, or white; of an uncertain figure, sometimes rather oblong, sometimes more orbicular; the divisions are parallel, the aperture very narrow.

SEMILUNUM. The shell of this is regular, loose, glabrous. It is found in the Adriatic and Red seas, and sometimes it is obtained fossil. The shell is scarcely larger than a grain of sand, white and yellowish; the whorls are pressed close together; the aperture is narrow, and compressed.

PLANORBIS. In this species the shell is orbicular, regular, flat, equal. It is found adhering to shells. The shell resembles a round scale, and when broken horizontally it exhibits the appearance of a spire in minute concentric circles.

SPIRILLUM. Shell regular, spiral, orbicular, pellucid, with round gradually decreasing whorls. It inhabits the ocean, on zoophytes, *fertularia*, and other marine substances; it resembles the next, which is a native of this country, but is much less than it.

\* SPIROBIS. Shell regular, spiral, orbicular, the whorls slightly caniculate above and inwardly, and growing gradually less towards the centre. It inhabits most seas, adhering to fungi and zoophytes. There is a variety; the shell is white, without polish, not complicated, but disposed singly on the substance to which it is attached; the aperture is circular.

\* TRIQUETRA. The shell of this is creeping, flexuous, triangular. It inhabits the ocean, adhering to marine substances, stones, and the bottoms of ships; is from half an inch to an inch long. The shell is white, pellucid, irregularly twisted, carinate on the back, sometimes denticulate, with a narrow circular aperture.

\* INTRICATA. Shell filiform, rough, round, intricately twisted. It inhabits the European and Indian seas, and often on our own coasts, upon shells. The shell is of a greenish-white, a little rugged and coarse.

FILOCRANA. Shell capillary, fasciculate, in branched complications, and cancellate. It inhabits the Mediterranean; is four inches long, and forms a beautiful kind of network.

GRANULATA. The shell of this is round, spiral, glomerate, with elevated ribs on the upper side. It inhabits the North seas, in large masses, adhering to stones, shells, &c. The shell is white, and the size of a coriander seed.

\* CONTORTUPLICATA. The shell is angular, rugged, and irregularly entwined. It is found in the European and American seas, and on our own coasts; is from three to four inches long; and sometimes it is as large as a goose-quill; the shell is white, cinereous, or yellowish-brown; within it is smooth, transversely striate.

GLOMERATA. The shell of this species is round, glomerate, with decussate wrinkles. It inhabits the European and Atlantic seas, in large masses. The shell is white, grey, or brownish; within it is smooth.

LUMBRICALIS. The shell of this is round, flexuous, with a spiral acute tip. There are three varieties of this species, which are found in the Atlantic and Indian seas, in large masses. The shell is from three to five inches long, transversely ribbed and longitudinally wrinkled.

POLYTHALAMIA. The shell of this is likewise round, diaphanous, smooth, straightish, with numerous internal divisions. It inhabits the Mediterranean and Indian seas, under the sand. The shell is outwardly white, transversely wrinkled, and annulate; the inside is separated by imperforated convex and concave divisions, making it appear as if it consisted of numerous united tubes.

ARENARIA. Shell jointed, entire, distinct, flattish beneath. It is found in India, and divers parts of the coast of Africa. It is probably a teredo, hereafter to be described. The shell is white, with pale brown undulate rays, or whitish; the outside cancellate, within it is smooth; spirally twisted: there are about a hundred striae, which are sometimes nodulous.

ANGUINA. Shell roundish, sub-spiral, with a longitudinal jointed cleft. It inhabits the Indian ocean; varies much in figure, being sometimes round and sometimes angular; it is more or less flexuous, glabrous or rough, with the joints of the cleft often obsolete. There is a variety of this species.

\* VERMICULARIS. Shell round, tapering, curved, wrinkled. It inhabits the European seas, and is from two to three inches long. The shell is whitish, ending in an obtuse point; the inhabitant is of a bright scarlet, with elegantly feathered tentacula, from the middle of which arises a trumpet-shaped tube, and a lesser simple one.

PENIS. The shell of this is round, straight, taper, with a dilated radiate larger extremity; the disk is covered with cylindrical pores. This is denominated the *watering-pot*. It is found chiefly in the Indian ocean. The shell is white or cinereous, with a faint shade of red; smoothish, tapering, and open at the small end; the dilated margin at the larger end

## SERPULA.

end terminating in numerous small tubes; the disk is convex, and covered with round perforations, with a longitudinal one in the middle.

**ECHINATA.** Shell roundish, flexuous, rosy, with numerous rows of prickles, obtuse at the end. It is the size of a crow's quill; the aperture is margined.

**OCREA.** The shell of this is roundish, striate, brown. It inhabits the Indian ocean, usually affixed to corals.

**PROTENSA.** Shell polished, smoothish, with annulate plaits, a little tapering towards the end. It is found in the Indian and American seas, and is the size of a quill. The shell is ivory, whitish or blueish, either straight or partly bent.

**DECUSSATA.** Shell round, with decussate striæ, slightly wrinkled, flexuous, red, within smooth and white.

**PROBOSCIDEA.** The shell is smooth and white; the broader part is straight and transversely plaited. The shell is from two to four inches long, white, or of a dusky brown.

**AFRA.** Shell sub-striate, yellowish-brown, round, twisted into three whorls, with a central tip. It is found about the coasts of the island of Goree.

**CEREOLUS.** Shell round, smooth, yellowish, many times twisted. It inhabits America. The shell is long and narrow.

**CORNUCOPIÆ.** Shell conic, spirally twisted, yellowish, with brown bands; the middle is round and twisted; the aperture is orbicular. The shell, as to its form, is obtuse at the tip.

**GOREENSIS.** The shell is round, cancellate, yellow, within horny. It is found at Goree, fixed to testaceous substances and wood; is from eight to nine inches long, with elevated striæ; the longitudinal ones are crowded.

**INTESTINALIS.** Shell triangular, twisted, fragile, tuberculate, with hollow dots. This is found on the African coast. The shell is whitish, singularly twisted, sub-umbilicate, within glabrous.

**INFUNDIBULUM.** The shell is round, white, transversely striate, and thrice twisted; the first bend appearing as if composed of five funnels placed on each other.

**PYRAMIDALIS.** Shell cinereous, above convex, beneath flat, pyramidal, hence its specific name, and it is many times twisted, the bends decreasing inwardly. It is found in the Indian sea, adhering to testaceous substances about an inch long, open at the narrower end; sometimes it is straightish, or a little bent.

**DENTICULATA.** The shell of this is white, round, subulate, straight, toothed at the sides, with a longitudinal glabrous rib in the middle; the tip is a little incurved and glabrous. It is found adhering to the *Lepas tintinnabulum*, and is about three-quarters of an inch long.

**MELITENSIS.** Shell roundish, twisted, umbilicate, with decussate striæ, and longitudinal nodulous ribs, within smooth, with numerous divisions. It is found fossil in Malta. The two first bends are placed on each other.

**NORWEGICA.** The shell of this is round, smooth, incurved, with a nearly obsolete undulate base: the mouth is obliquely truncate. It is found, as its specific name denotes, in Norway.

**PORRECTA.** Shell round, smooth, polished, ascending in a flexuous manner from the spiral base. It inhabits the North seas. The shell resembles the *S. spirillum*, but is whiter, pellucid, and not rugged; the inhabitant is short, with a red back and paler sides.

**VITREA.** The shell is round, regular, spiral, orbicular, pellucid, shining, wrinkled, with a thickened aperture. This

species is found in the Greenland seas, on *fertulariæ*, *fuci*, *stones*, and divers marine subterraneous. It resembles the *S. glomerata*; the shell is thick, umbilicate, not a line in diameter, and sometimes it is of a reddish colour.

**CANCELLATA.** Shell spiral, glomerate, with three grooves, the lower groove interrupted by transverse lines. It inhabits the Greenland seas, and resembles the *S. granulata*. Shell white, grey or greenish, the aperture is two-toothed.

**STELLARIS.** Shell sub-orbicular, umbilicate, convex, radiate with wrinkles. This also is found in the Greenland seas, on *fertulariæ* and *stones*. The shell is scarcely larger than a needle, violet, reddish-brown, or yellowish radiate with white; beneath it is flat, with a single whorl or bend; the aperture is very minute.

**GIGANTEA.** The shell of this is somewhat triangular, with a little bend, gradually tapering, violet, within smooth, pale yellow, the aperture is white, with undulate striæ, and armed with a conic tooth. It inhabits Africa and America, attached to rocks and corals. The shell is six inches high, and as thick as the little finger. The inhabitant is whitish.

**CINEREA.** The shell is filiform, glabrous, conglomerate, perforated. It inhabits the shores of Massilia; it is glabrous, of a greyish-white, and flexuous.

\* **SULCATA.** Shell with two whorls, deeply and spirally grooved. It inhabits the coasts of Pembroke-shire, on the roots of the *Fucus digitatus*. It is a minute shell, of a greenish colour.

\* **OVALIS.** Shell sub-oval, imperforated. It is found at Tenby. The shell has two bends, which form an oval; it is never perforated, and is minute.

\* **REFLEXA.** The shell is regular, rounded, with a reflected margin at the aperture. This is found on the Pembroke-shire sands. It is minute; shell glossy, white, perforated; the aperture is above the plane of the spire.

\* **CORNEA.** The shell is regular, rounded, and pellucid, with three whorls. This also is an inhabitant on the Pembroke-shire coast. It is brown and horny.

\* **BICORNIS.** Shell femiunar, ventricose, white, opaque, glossy. It is found at Sandwich and Reculver, and is minute.

\* **PERFORATA.** Shell femiunar, perforated, white, opaque, glossy. It inhabits Sandwich, as do all those that will be hereafter described. This is, however, as well as the next, very rare and minute.

\* **LACTEA.** The shell is ovate, thin, smooth, pellucid, with milky veins.

\* **LAGENA.** Shell rounded, striate, grooved, with a narrow neck. This is described, as are all those which are found in this country, in Adams's work on the Microscope. The shell of this is exactly shaped like an oil-flask, and is whitish.

\* **RETORTA.** Shell rounded, margined, with a slender recurved neck. The shell is white, opaque, shaped something like the retort used by chemists.

**INCURVATA.** The shell is straight, with three close whorls at the smaller end. The shell is white and transparent, and resembles, in some respects, the *Nautilus femi-litius*.

**SERPYPILLUM**, in *Botany*, sometimes written *Serpillum*, so called from its humble creeping mode of growth. See **THYMUS**.

**SERQUEUX**, in *Geography*, a town of France, in the department of the Upper Marne; 3 miles N. of Bour-bonne.

**SERRA,**

SERRA, PAOLO, in *Biography*, author of an elaborate treatise on solmifiation, published at Rome in 1768, small folio, entitled "Introduzione Armonica Sopra la nuova ferie de' Suoni modulati oggidì, e modo di rettamente, e piu facilmente intonarla;" or, "Harmonical Introduction to a new series of modulated sounds, and a method for accurately, and with greater facility, learning to name and produce them with the voice."

The author begins, cap. 1, with the origin of music, its utility, and the different modes of naming the notes in singing. After endeavouring to rob Guido of the invention of the hexachord and solmifiation, and condemning its use, he proposes a new method of naming the notes in learning to sing; assigning a specific name to every sound in the scale ending with the vowels A, E, I; as *ca* for a flat note, *ce* for a natural note, and *ci* for a sharp note; beginning each sound with the letters now in use in the Septenary, by which means the student is disembarassed from all mutations, and every sound in the scale has a specific and invariable name appropriated to it.

The image shows two staves of musical notation. The first staff is for the scale C-D-E-F. Above the notes are the letters C, D, E, F. Below the notes are the syllables CA CE CI, DA DE DI, EA EE EI, FA FE FI. The second staff is for the scale G-A-B. Above the notes are the letters G, A, B. Below the notes are the syllables GA GE GI, A AO AU, BA BE BI. The notes are represented by circles on a five-line staff, with a treble clef on the left.

This method had the approbation of several of the best masters in Rome, who have signed a certificate of its effect upon the studies of a young singer of the name of Benedetti, who was rendered capable by it, in less than a year, of fingering at sight any vocal music that was put before him, even without accompaniment. Benedetti has since sung the first man's part in the operas of several of the principal cities of Italy; and, perhaps, his genius may be such, as would have enabled him to have done the same by any other method, with equal study and practice. Instrumental performers, at present, are not plagued with the ancient names of the notes and mutations, but learn them by the simple letters of the alphabet; and yet we have never heard of one that has been able to play at sight in a year's time.

Upon the whole, the alphabetic names of the notes seem the most simple and useful for every purpose but that of exercising the voice, which is best done by the vowels; and it may be said, that to *syllabize* in quick passages is little more than to speak, but to *vocalize* is to sing. However, we were told by a scholar of the famous Durante, that while he was in the conservatorio of St. Onofrio, at Naples, when the boys used to be tormenting themselves about the mutations, and the names of notes in transposed keys, with double flats and sharps, Durante cried out, "Queste note intonate, chiamate poi anche diavole se volete, ma intonate." Meaning, that if they did but hit the intervals right, and in tune, he did not care what they were called. And, perhaps, what Pope says of different forms of government, may be more justly applied to these several methods of singing.

"Whate'er is best administer'd is best."

As, in the use of any of them, whoever has the best matter,

and second his instructions with the greatest degree of intelligence and industry, will be the most likely to succeed. And when we recollect the great abilities and enchanting powers of many singers of past times, who have been obliged to articulate every note of their *solfeggi* in the most rapid movements, we may apply to the new systems what M. Rousseau said with respect to his own: "That the public has done very wisely to reject them, and to send their authors to the land of vain speculations." For innovators will always find, that a bad method, already known, will be preferred to a good method that is to learn.

SERRA, in *Botany*, a genus of plants, so called in the *Flora Peruviana*, after a Spanish botanist of the same name, who has studied the plants of Minorca. *De Theis*.

SERRA, in *Geography*, a town of France, in the department of the Jemappe, and chief place of a canton, in the district of Corté. The canton contains 2171 inhabitants.

SERRA, a town of Corfica; 11 miles S.S.W. of Cervione.

SERRA de *Azenhao*, mountains of Portugal, in Alentejo; 4 miles N. of Monfort.

SERRA d'*Alkoba*, mountains of Portugal, in the province of Beira, between Viseu and Bragança Nova.

SERRA de *Bouzeno*, mountains of Portugal, in Alentejo; 4 miles S. of Portalegre.

SERRA de *Culdeiras*, mountains of Portugal, between Algarva and Alentejo.

SERRA da *Estrica*, mountains of Portugal, in the province of Entre Duero e Minho; 18 miles N. of Bragança.

SERRA *Falperra*, a town of Portugal, in Tras los Montes; 15 miles W. of Mirandela.

SERRA de *Marã*, a mountain of Portugal, in the province of Tras los Montes; 10 miles S. of Chaves.

SERRA de *Monchique*, mountains of Portugal, between Alentejo and Algarva.

SERRA de *Momil*, mountains of Portugal, between Mirandela and Torre de Moncorvo.

SERRA de *Querera*, a town of Africa, in Lower Guinea, on the river Camarones.

SERRA de *Reboardaos*, mountains of Portugal, south of Bragança, in Tras los Montes.

SERRA de *St. Miguel*, mountains of Portugal, in Alentejo, on the south side of the Tagus; 15 miles N.N.W. of Castello de Vide.

SERRA de *Salvador*, mountains of Portugal, in Alentejo; 8 miles E. of Arronches.

SERRA *Piscis*, in *Ichthyology*, a name given by many authors to the *pristis*, or *jacw-fish*.

SERRA is also a name given by Pliny to a species of the balites, called by the generality of writers *scelopax*. It is distinguished by Ardeidi by the name of the balites, with two spines in the place of the belly-fins, and one behind the anus. See TRUMPET-fish.

SERRAE, in *Geography*, a town of European Turkey, in Macedonia, the see of a Greek archbishop; 36 miles E.N.E. of Saloniki.

SERRAIN, a town of Arabia, in the province of Hedjas; 40 miles S.W. of Mecca. N. lat. 21° 5'.

SERRANA, or *Pearl Island*, a small island in the Caribbean sea, so called from Serrana, the commander of a Spanish vessel in the time of Charles V., who was shipwrecked on the coast. N. lat. 14° 5'. W. long. 78° 50'.

SERRANILLA ISLANDS, a cluster of small islands in the bay of Honduras. N. lat. 16° 10'. W. long. 80° 10'.

SERRAPETRONA, a town of Italy; 7 miles S.W. of Ancona.

**SERRATA**, a name given by some of the Roman authors to the plant which the Gauls, according to Pliny, had named *betonica*, and which the Greeks called *cestrum-psuchrotrophon* and *priorites*. This was evidently the same plant with our *ferratula*, or saw-wort; but besides this there was another plant called by this name, and which, according to Pliny, was the *chamædry*s or germander of the Greeks.

Diofcorides fays nothing of the *chamædry*s, but that its leaves were small. And it is much more probable, that the world should take the idea of a saw from the leaves of the *ferratula* than from those of this plant, they being much less nicely denticulated than those. So that those who have been influenced by Pliny, to suppose the germander and *ferratula* of the ancients to be the same plant, are in the wrong, though they have the countenance of this so generally reputed authentic author for it.

**SERRATE FLIES**, in *Natural History*, a name given by authors to certain flies, distinguished from all the other kinds by their having a weapon resembling a double saw, placed at the hinder part of the body; this serves several species of them to make holes in the branches of trees, in which they deposit their eggs; but there are some of them which do not seem to make any use of this curious instrument, though they have it. See *ROSE-FLY*.

The fly of this kind that lays its eggs on the gooseberry-bush, deposits them only on the surface of the middle rib of the leaf; and the osier-fly, which is one of this genus, produced from a bastard caterpillar of the osier, lays its eggs on the intermediate surface of the leaves between the ribs.

There appears to be no use made of this curious instrument in the depositing of these eggs, since they are only laid in rows upon the leaves, and fixed to them by means of a viscous fluid which covers them. It is a very remarkable property in the eggs of this genus of flies, that they grow much larger after they are laid. This is observable in the eggs of the common rose-fly, which are at first buried in the wood, and by their growth force out the surface into tumours of an oval figure; but in those of the osier-fly it is most beautifully seen, and the whole growth of the foetus in them is clearly seen, on examining them at different times of their growth, which may be easily done without disturbing them, as they lie naked on the surface of the leaf.

There seems a plain proof that the egg receives some sort of benefit, and that a very essential one to its preservation, from the juices of the plant on which it is deposited, since, if those leaves be pulled off from the plant, and left to dry, the eggs always dry up with them, and perish; whereas, if the ends of these leaves be put into water, and the leaf be by that means preserved fresh and juicy, the creature hatches from it as well as if it was left upon the tree. Reaumur's *Hist. Inf.* vol. ix. p. 164.

**SERRATED LEAF**, in *Botany*. See *LEAF*.

**SERRATI**, in the *History of Coinage*, a name anciently given to Syrian, Roman consular, and some few other coins, which were ornamented by cutting out regular notches on the edges. Tacitus fays, that the Germans preferred these to other Roman coins. But the old forgers imitated this kind of incision, which was intended to prevent forgery, by shewing the inside of the metal.

**SERRATULA**, in *Botany*, so called by the early writers on plants, from the fine serratures of the leaves, in the original species, which stands first on our list.—*Bauh. Pin.* 235. *Linn. Gen.* 408. *Schreb.* 542. *Willd. Sp. Pl.* v. 3. 1638. *Mart. Mill. Dict.* v. 4. *Sm. Fl. Brit.* 845. *Prodr. Fl. Græc. Sibth.* v. 2. 148. *Ait. Hort. Kew.* v. 4. 472. *Dill. Gill. t.* 8. *Juss.* 174. *Lamarck Illustr. t.* 666. f. 1. *Gært.* t. 162?—Class and order, *Syngenesia*

*Polygamia-aqualis*. Nat. Ord. *Compositæ capitata*, Linn. *Cinara-cephale*, Juss.

Gen. Ch. *Common Calyx* oblong, nearly cylindrical, closely imbricated, with numerous, lanceolate, erect, unarmed scales. *Cor.* compound, tubular, uniform. Florets numerous, equal, all perfect, of one petal, funnel-shaped; the tube inflexed; limb tumid, five-cleft. *Stam.* Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen obovate; style thread-shaped, the length of the stamens; stigmas two, oblong, revolute. *Peric.* none, except the unchanged calyx. *Seeds* solitary, obovate. Down sessile, toothed or feathery. *Recept.* chaffy or hairy.

Ess. Ch. Receptacle chaffy or hairy. Calyx imbricated, cylindrical, unarmed. Seed-down feathery or toothed.

Obs. *Carduus* and *Cnicus* are distinguished from this genus by their more swelling, or nearly globose, calyx, with spinous scales. We know not what Gærtner has procured for the *Carduus cyanoides*, which he represents with unarmed scales, and therefore properly refers to *Serratula*; but the true Linnæan plant has spinous scales. This learned author would remove to the present genus a number of species from *Cnicus*, *Carduus*, and *Centaurea*, of which he names but two, *Cnicus centauroides*, and *Centaurea Rhaiponticum*, certainly very remarkable plants, and strictly akin, but in our opinion they answer very imperfectly to the idea of a *Serratula*. We content ourselves with following Willdenow in the main, though well aware of the ambiguity of some of the species, too prone to approach *Carduus* in their calyx, or *Centaurea* occasionally in their marginal florets. We persist, however, in excluding *S. arvensis*, which is, in character and habit, a most evident and certain *Carduus*, or rather *Cnicus*, as Mr. Curtis long ago demonstrated. Willdenow could scarcely have been acquainted with this common species, for he marks it as biennial, though no weed is more notorious for its deeply creeping, almost indestructible, roots. See *Fl. Brit.* 851, and *Curt. Lond. fasc.* 6. t. 57.—Two genera, with a naked receptacle, and other differences of character, are properly separated by Schreber, Willdenow, and others, from *Serratula*. See *LIATRIS* and *VERNONIA*.

1. *S. tinctoria*. Common Saw-wort. Linn. *Sp. Pl.* 1144. *Willd. n.* 1. *Fl. Brit. n.* 1. *Ait. n.* 1. *Fl. Dan.* t. 281. *Engl. Bot.* t. 38. (*Serratula*; *Ger. Em.* 713. *Matth. Valgr.* v. 2. 295. *Camer. Epit.* 652.)—Leaves sharply serrated, somewhat ciliated, more or less pinnatifid at the lower part. Corymb level-topped. Florets uniform. Seed-down fringed.—Native of groves and bushy places, chiefly in the north of Europe; though the Abbé Scellini told Dr. Sibthorp he had gathered this plant near Constantinople. It is perennial, with a brown woody root, and flowers in July and August. The stem is upright, straight, stiff, leafy, angular, reddish, about two feet high, not much branched. Leaves alternate, smooth, of a deep shining green, with elegant, sharp, hair-pointed teeth; the radical ones stalked, undivided; the upperly, or variously pinnatifid. Flowers corymbose. Calyx purpleish-brown, now and then downy. Corolla crimson, occasionally white. This herb serves in Sweden to give a yellow colour to coarse woollen cloth.

2. *S. coronata*. Siberian Saw-wort. Linn. *Sp. Pl.* 1144. *Ait. n.* 2. (*S. præalta centauroides montana italica*; *Bocc. Mat.* 45. t. 37? *Carduus n.* 41; *Gmel. Sib.* v. 2. 49. t. 20.)—Leaves sharply serrated, somewhat ciliated, deeply pinnatifid. Corymb level-topped. Florets of the circumference female, longer than the rest.—Native of moist parts of Siberia, flowering in the end of June. If *Boccon's* synonym be right, the plant grows also on mountains in

## SERRATULA.

Italy. Gmelin says it is used in the former country for dyeing yellow, birch-leaves being superadded. This species is thrice as large as the *tinctoria*; the *leaves* always deeply pinnatifid; the *flowers* much larger, furnished with radiating marginal florets, which, though destitute of *stamens*, produce *seed*.

3. *S. quinquefolia*. Five-leaved Saw-wort. Willd. n. 3. Ait. n. 3.—Leaves ferrated, deeply pinnatifid, five or seven-lobed. Flowers simply corymbose. Inner scales of the calyx elongated and coloured.—Native of the north of Persia. Introduced into the gardens of England by Mr. Bush, in 1804. A hardy perennial, flowering in July and August. Very like the last, but the *leaves* have only two or three pair of lobes; the *calyx* is rather smaller, and not downy, its long coloured inner scales resembling a radiant *corolla*. *Florets* uniform. *Willdenow*. The specific name is exceptional, for, by this author's own account, the *leaves* are only pinnatifid.

4. *S. humilis*. Humble Saw-wort. Desfont. Atlant. v. 2. 244. t. 220. Willd. n. 4. (*Jacea lupina*, *carlinæ capitulo acule, tota incana*; Bocc. Mus. 146? *J. incana chamaeleonis capitulo*; *ibid.* t. 109?)—Leaves pinnatifid, with oblong entire segments; downy beneath. Flower solitary. Calyx hoary, with spreading-pointed scales.—Native of Sicily and Barbary, flowering in summer. An elegant little perennial plant, with several spreading radical *leaves*, either simply or interruptedly, but always very deeply, pinnatifid; smooth above. *Flower* rose-coloured. Its *stalk* appears to vary in length, being sometimes nearly wanting.

5. *S. mollis*. Soft-leaved Saw-wort. Cavan. Ic. v. 1. 62. t. 90. f. 1. Willd. n. 5.—Leaves pinnatifid, with oblong, obtuse, entire segments; downy beneath. Flower solitary. Calyx downy, with erect scales.—Native of hills in Spain, flowering in June. Cavanilles says the root is annual, but Willdenow thought it seemed perennial. The latter, who had seen dried specimens of this and the last, was persuaded of their being distinct, and, besides the characters given above, he remarks that the *seed-down* of the present species is most feathery.

6. *S. pygmaea*. Dwarf Linear Saw-wort. Jacq. Antr. v. 5. 20. t. 440. Willd. n. 6. (*Cnicus pygmaeus*; Linn. Sp. Pl. 1156.)—Leaves nearly linear, revolute, loosely hairy. Stem leafy, hairy, single-flowered. Calyx-scales ovato-lanceolate, erect.—Found by Jacquin on the celebrated Austrian mountain called *Schneeberg*, in 1761. Clusius appears to have gathered the same in Hungary, and Scopoli in Carniola. The perennial *root*, furnished with long black fibres, is crowned with a tuft of numerous spreading *leaves*, each two or three inches long, not half an inch wide, green on both sides, though clothed with loose scattered white hairs; their margin either entire, or distantly toothed. Similar, though rather shorter, *leaves* clothe the simple *stem*, which is from two to five inches high, hollow, hairy, bearing one upright purplish *flower*, with prominent violet *anthers*. The scales of the *calyx* are broad, flat, purplish and downy. This is one of the rarest alpine plants, nearly related to the following, but certainly distinct.

7. *S. alpina*. Alpine Saw-wort. Linn. Sp. Pl. 1145. Willd. n. 7. Fl. Brit. n. 2. Engl. Bot. t. 599. Lightf. Scot. 448. t. 19. (*Cirsium montanum humile, cynoglossæ folio, polyanthemum*; Dill. Elth. 82. t. 70.)

8. *S. discolor*. Willd. n. 8. (*Cirsium* n. 179; Hall. Hist. v. 1. 77. t. 6. C. n. 52; Gmel. Sib. v. 2. 67. t. 26, Herb. Linn. from the author. *Carduus mollis, foliis latius*; Ger Em. 1184.)

Leaves cottony and white beneath, toothed, pointed, ovato-lanceolate, undivided; the radical ones somewhat ovate or heart-shaped. Flowers corymbose. Calyx clothed with soft hairs.—Native of the highest mountains of Europe, particularly Siberia, Wales, Scotland, and Switzerland, flowering in July and August. There can be no doubt that all the synonyms here cited belong to one species, nor is it easy to mark the limits of even its varieties. The *root* is perennial, tough, and woody. *Stem* from three to twelve inches, or more, in height, simple, leafy, striated, cottony, crowned with a level-topped tuft of elegant *flowers*, on stalks of various lengths. *Calyx* of many soft, brown, hairy scales. *Florets* pink, with blue or violet anthers. The *leaves* are excessively variable in shape, from lanceolate to broadly heart-shaped; their margin toothed, sometimes wavy; their *footstalks* long and slender, short and thick, or altogether wanting. The upper surface of each *leaf* is green, smooth, and nearly or quite naked; the under covered with dense, white, cottony down. The narrowest-leaved specimens grow in rich ground, amongst other plants.

8. *S. angustifolia*. Narrow-leaved Saw-wort. Willd. n. 9. (*S. alpina*  $\delta$ , *angustifolia*; Linn. Sp. Pl. 1145. *Cirsium* n. 59; Gmel. Sib. v. 2. 78. t. 33. Herb. Linn. from the author.)—Leaves linear, revolute, entire; rather hairy beneath. Flowers somewhat racemose. Bractæes awl-shaped.—Gathered by Steller, on the banks of rivers in the eastern part of Siberia. A much more slender plant than any variety of the preceding. The *stem* is eighteen to twenty-four inches high, erect, slender, hollow, striated, purplish, nearly smooth. *Leaves* scattered, hardly a line broad, quite entire, paler, and a little hairy, but not cottony, beneath. *Flowers* few, on long, simple, distant, rather racemose than corymbose, stalks. Scales of the *calyx* ovate, pointed, purplish or brown, hairy within.

9. *S. falcifolia*. Willow-leaved Saw-wort. Linn. Sp. Pl. 1145. Willd. n. 10. Ait. n. 5. (*Cirsium* n. 53; Gmel. Sib. v. 2. 69. t. 27.)—Leaves linear-lanceolate, entire; white and cottony beneath. Corymb compound, leafy. Scales of the calyx elliptical, ribbed, downy.—Native of Siberia, in dry open rocky places, where it flowers towards the end of July. Mr. Joseph Bush is said to have brought this species into the English gardens in 1796. It is an elegant hardy perennial, distinguished by the snowy whiteness of the backs of its *leaves*, whose edges are scarcely, if at all, revolute; their base tapering down into a bordered *footstalk*. The *flowers* rather more resemble those of *S. tinctoria* than of *alpina*, but the *calyx* is slightly cottony.

10. *S. indica*. Indian Saw-wort. Willd. n. 11.—“Leaves linear-lanceolate, ferrated, roughish. Stem panicled. Corymbs level-topped.”—Native of the East Indies. *Stem* furrowed, smooth, four feet high. Upper *leaves* entire. *Corymbs* terminating the branches. *Calyx* cylindrical, with lanceolate, scarious, imbricated scales. *Seed-down* chaffy, lanceolate, ciliated. *Receptacle* clothed with lanceolate, acute, ferrated, chaffy scales. *Willdenow*.

11. *S. multiflora*. Many-flowered Saw-wort. Linn. Sp. Pl. 1145. Willd. n. 12. (*Cirsium* n. 54; Gmel. Sib. v. 2. 71. t. 28.)—Leaves lanceolate, rough, somewhat decurrent, nearly entire; woolly beneath. Stem repeatedly corymbose, many-flowered. Scales of the calyx lanceolate, keeled.—Gathered by Gmelin in mountainous parts of Siberia. Dr. Fischer has sent us a less luxuriant specimen from mount Caucasus. The *stems* are said to be decumbent. The *leaves* vary in breadth, and are sometimes revolute; the radical ones coarsely toothed. Their green upper surface is rough like a file;

file; the under clothed with loose white cottony wool. *Flowers* more or less numerous, corymbose, rose-coloured, with an elegant, slender, purplish, slightly downy, calyx. Gmelin himself justly says that the *flowers* in his plate are too large; yet Linnæus on that account doubts the certainty of his synonym, for which there can be no reason.

12. *S. caspica*. Caspian Saw-wort. "Pall. It. v. 2. append. n. 121. t. Z." Willd. n. 13.—"Leaves lanceolate, obtuse, entire, smooth, somewhat fleshy. Stem corymbose."—Native of the borders of the Caspian sea. The *seed-down* is hairy and fringed. *Receptacle* villous. Willdenow.

13. *S. mucronata*. Pointed-sealed Saw-wort. Desfont. Atlant. v. 2. 243. t. 219. Willd. n. 14.—Leaves elliptic-oblong, nearly entire, smooth. Stem with few flowers. Scales of the calyx with recurved membranous points.—Found by Desfontaines, on hills in Barbary near Mascara, and on mount Atlas, flowering in the early spring. *Root* perennial. Whole *plant* very smooth, near two feet high. *Leaves* alternate, entire or finely toothed, from four to six inches long. *Flowers* from one to three, rather large, pink, or purplish, with an ovate squarrose calyx. *Seed-down* and hairs of the *receptacle* simple, slender.

14. *S. amara*. Bitter Saw-wort. Linn. Sp. Pl. 1148. Willd. n. 15. (Cirsium n. 55; Gmel. Sib. v. 2. 72. t. 29.)—Leaves lanceolate, rough-edged, naked, somewhat decurrent. *Flowers* corymbose. Scales of the calyx dilated and rounded at the extremity.—Native of dry open fields in Siberia, on a saline soil, abundantly. Gmelin. *Root* as thick as the little finger, perennial, bitter, with a saline flavour. *Stem* from a span to one or two cubits high, simple or branched, leafy, angular, and furrowed. *Leaves* four or five inches long, and one broad, coriaceous, tapering at each end, naked and nearly smooth on both sides, except the edges and midrib: the lower ones stalked, toothed; the upper generally decurrent, and entire. *Flowers* several, purple, the size of *Centaurea nigra* or *Jacea*, but in the aspect and hue of their calyx most resembling the latter, except that the round apex of each scale, though jagged, is not fringed.

15. *S. centauroides*. Centaury-like Saw-wort. Linn. Sp. Pl. 1148. Willd. n. 16. Ait. n. 6. (Carduus n. 38; Gmel. Sib. v. 2. 44. t. 17.)—Leaves deeply pinnatifid, acute, smooth, unarmed. Stem branched. *Flowers* solitary. Scales of the calyx partly pointed; the inner ones dilated and membranous.—Native of Siberia. Sent by sir Joseph Banks to Kew, in 1804. A hardy perennial, flowering in July and August. This has the habit of several *Centaurea*, but wants the neuter marginal florets. The *stem* is a foot or more in height, alternately branched, leafy, angular, smooth. *Leaves* rigid or coriaceous, with deep, entire, decurrent segments. *Flowers* solitary at the top of each branch, large, purple. *Calyx* ovate, of many ovate acute scales, several of the middlemost of which bear a short spine, while the inner ones are much elongated into a linear, membranous-tipped appendage. The genus of this plant cannot but be considered as very doubtful, nor can we refer it without scruple to *Serratula*, or *Centaurea*; perhaps we should, like Gmelin, remove it to *Carduus* or *Cnicus*, the calyx answering very nearly to that of the *arvensis*.

16. *S. japonica*. Japan Saw-wort. Thunb. Jap. 305. Willd. n. 17.—Leaves pinnatifid, toothed, rough on both sides. *Corymb* compound. Scales of the calyx dilated and rounded at the extremity. Gathered by Thunberg in Japan. The *stem* is a yard high, scarcely branched, leafy, strongly angular and furrowed, rough with minute hairs. *Leaves* stalked, somewhat lyrate, three or four inches long. *Flowers*

numerous, in a compound level-topped corymb, rather smaller than those of *Serratula arvensis*. *Calyx-scales* tipped with an elegant, purple, notched, membranous dilatation.

17. *S. ciliata*. Fringed Saw-wort. Vahl. Symb. v. 1. 67. Willd. n. 18.—Leaves sessile, lanceolate, undivided, fringed with minute spines; downy underneath.—Gathered by Forstkall, in gardens at the village of Bujuchitari, near Constantinople. Willdenow erroneously makes this species a native of Egypt. Forstkall took it for the Linnæan *S. arvensis*. Vahl, who had examined his original specimens, describes the *stem* as herbaceous, branched, striated; hoary in the upper part. *Leaves* sessile, an inch and a half long, tapering at the base, obtuse, finely serrated, with spinous teeth; the upper side green, shaggy; the under hoary and downy. *Flowers* smaller than a hazel-nut, stalked, two or three at the end of each branch. *Calyx-scales* smooth; the outermost ovate, keeled at the summit, and pointed; the inner ones lanceolate. *Seed-down* feathery. This may possibly, like the following, belong to *Cnicus*.

18. *S. setosa*. Brittle Saw-wort. Willd. n. 19.—"Leaves oblong, smooth, finely serrated, fringed with bristles, obtuse, pointed. Stem corymbose."—Native of Silesia; observed by the Rev. Mr. Seeliger. *Root* biennial. *Stem* furrowed, smooth, corymbose and level-topped. *Leaves* copious, alternate, an inch long (or broad?) green on both sides, smooth, undivided, very minutely serrated, each serrature tipped with a brittle point. *Flower-stalks* hoary. *Calyx* slightly downy, with ovate, acute, obscurely-pointed scales. Willdenow, from whom we borrow this description, says the plant is like *Cnicus* (his *Serratula arvensis*, except in the form of its *leaves*, and smallness of the *flowers*. If so, it perhaps is likewise a real *Cnicus*, and perennial; see our observations under the generic character.

SERRATULA, in *Gardening*, contains plants of the tall, hardy, herbaceous, perennial kind, of which the species cultivated are; the long-leaved saw-wort (*S. noveboracensis*); the tall saw-wort (*S. præalta*); the glaucous-leaved saw-wort (*S. glauca*); the rough-headed saw-wort (*S. squarrosa*); the ragged-cupped saw-wort (*S. scariosa*); and the spiked saw-wort (*S. spicata*).

*Method of Culture*.—These plants may all be increased by parting the roots, and planting them out in the autumn, when the stems decay, or in the spring; but the former is the better season. The old plants should not be parted oftener than every third year, and then not too small.

They are likewise all capable of being increased by seeds, when they can be had good, which should be sown in the autumn or early spring, in a border to the east, in slight drills. When the plants are a few inches high, they should be pricked out in nursery-rows to remain till the following autumn, and then planted out where they are to remain.

They afford ornament in the borders, clumps, &c. being planted to the middle or the back parts.

SERRATUM, and SERRULATUM, *Folium*, in *Botany*, so called from *serra*, a saw, the teeth of which are imitated in their margins. See LEAF.

SERRATUS, in *Anatomy*, a name given to different muscles attached to the ribs, and arising by several distinct portions, so as to have a serrated edge. In French they are called *denté*.

SERRATUS *Anticus*, the name under which Albinus describes the pectoralis minor. It is also called *ferratus minor anticus*.

SERRATUS *Magnus*, (*ferratus major anticus*; le grand denté; scapulo costien,) a large muscle of the shoulder, broad and flat, lying between the scapula and the chest, and extending

extending from the nine upper ribs to the basis of the scapula. It is irregularly four-sided, broader below and in front than above and behind. It arises from the eight or nine upper ribs by as many distinct pointed portions, which are first tendinous, then fleshy. The first, which is broad, very thick, short, and distinct from the rest, arises from the outer edge of the first rib, towards its back part, from the second, and from an intermediate aponeurosis. The second, third, and fourth, broad and thin, arise from the external surfaces of the second, third, and fourth ribs, in oblique lines directed from above and behind, downwards and forwards. The four or five last, narrower and increasing in length downwards, arise from the upper edge and external surface of the corresponding ribs, and are placed between the digitations of the obliquus externus abdominis. From the origins just enumerated, the fibres of the muscle proceed, divided, particularly below, into fasciculi corresponding to each digitation, separated by cellular lines, and soon forming three distinct portions. The superior division is thick, narrow, and short, extends from the two first ribs to the superior angle of the scapula, ascending a little, and covering the upper edge of the second portion, to which it is united. The middle division, broad and thin, goes from the second, third, and fourth ribs to the upper three-fourths of the basis of the scapula; its fibres proceed horizontally from before backwards, except the inferior ones, which descend a little. The inferior portion of the muscle passes from the fifth, sixth, seventh, and eighth ribs to the inferior fourth of the basis of the scapula, and the inferior angle of the bone. This part is thick, radiated, broad in front, and narrow behind. The superior fibres of this portion go nearly horizontally from before backwards; the inferior ones are directed at the same time from below upwards, and are more oblique in proportion as they are lower: they are united towards the inferior angle of the bone.

The external surface of the serratus is covered, towards its lower and anterior part, by the skin, at the lower and posterior part by the latissimus dorsi. Above and towards the front it is covered by the pectoral muscles, by the axillary vessels, and the brachial plexus. In the rest of its extent it is in contact with the sub-scapularis. The external surface covers the seven or eight superior ribs, the external intercostal muscles, and behind a portion of the serratus superior pecticus. The upper edge of the muscle is the shortest, extending from the margin of the first rib to the superior angle of the scapula: the inferior, much longer, reaches from the eighth or ninth rib, or about two inches from its cartilage, obliquely to the inferior angle of the scapula. The anterior edge is the longest, and fixed to the external surface of the eight or nine first ribs, by the distinct pointed serræ or digitated portions, from which the name of the muscle has been derived: the posterior is fixed to the front edge of the basis of the scapula, and of the superior and inferior angles of the bone.

The action of the serratus anticus produces two different effects, according as the scapula or the ribs are the fixed point. In the first case, the scapula being fixed by the trapezius, rhomboid and levator muscles, it draws the ribs outwards, elevating those to which it is fixed by its lower digitations: in this respect it is a powerful agent of inspiration, concurring with the pectoral muscles. In the second case, it carries the scapula forwards, antagonizing the rhomboid, trapezius, &c. But it moreover draws the inferior angle forwards, and consequently moves the upper and anterior angle of the bone, forming the shoulder, upwards. Thus the serratus anticus is an important muscle in supporting

burdens carried on the shoulders. In this case the diaphragm and abdominal muscles are put in action to draw down the ribs, fix them, and prevent them from yielding to the efforts of the serratus.

*SERRATUS Major Anticus.* See *SERRATUS Anticus.*

*SERRATUS Pecticus Inferior,* (dentelé postérieur inférieur; lombocœlien,) is a broad, thin, and flat muscle, situated at the lower part of the back, and extending from the spinous processes of the vertebræ to the ribs. It arises from the spinous processes of the two last dorsal vertebræ, of the three first lumbar, and the intervening interspinal ligaments, by a broad aponeurosis, composing one half of the muscle, common to it and the latissimus dorsi, composed of parallel fibres, directed obliquely upwards and outwards. This aponeurosis is connected in front to that of the transversus abdominis, and by its lower edge to the obliquus internus. The muscular fibres, passing with the same obliquity as those of the aponeurosis, form four fasciculi or pointed serrated portions, of which the first and broadest is fixed to the lower edge, and near the angle of the second false rib; and the three others, which are successively smaller, are also attached, by aponeurotic fibres, to the lower edge of the three succeeding ribs, farther from the angle. The posterior surface of this muscle is covered by the latissimus dorsi. The anterior surface covers the three last false ribs, the external intercostal muscles, the longissimus dorsi and sacrolumbalis, and the transversus abdominis. The upper edge is continuous with the thin aponeurosis, which immediately covers the longissimus dorsi and sacrolumbalis.

By drawing downwards the lower ribs, this muscle assists in expiration. It cannot produce any effect on the spine: it will confine the muscles lying at the side of the spine, and thus has the same effect as the serratus pecticus superior and the fascia extended between them.

*SERRATUS Pecticus Superior,* (dentelé postérieur supérieur; dorlocœlien,) is a very small and thin muscle, flat and four-sided, placed at the upper part of the back. It arises from the ligamentum nuchæ, the last cervical spinous process, and the two or three upper dorsal ones, by a thin aponeurosis, composed of parallel fibres, directed obliquely downwards and outwards. The fleshy fibres follow the same direction, forming a thin stratum, which terminates in four small fasciculi or serrated portions, ending in aponeurotic fibres, which are inserted in the upper edges of the second, third, fourth, and fifth ribs, near their angles. It is covered externally by the rhomboideus: and it covers the splenius, transversalis colli, the vertebral muscles, the ribs, and the corresponding intercostal muscles.

It will have the effect of elevating the ribs, and thereby of enlarging the chest, or assisting in inspiration.

*SERRAVALLE,* in *Geography,* a town of France, in the department of Marengo, on the Scrivia; 12 miles S. of Tortona.—Also, a town of France, in the department of the Sefia; 18 miles N. of Vercelli.—Also, a town of Italy, in the duchy of Mantua; 24 miles S.E. of Mantua.—Also, a town of Italy, in the Trevisan,  $2\frac{1}{2}$  miles in circumference, partly on a plain between two mountains, and partly on the mountains near the river Maschio, which runs through the middle of the town, and has its source in a small lake in the higher part of the town. At the extremity of the marketplace is the public palace, and at the lower end the cathedral church, containing some good paintings. The town and its suburbs comprehend two parishes, and 30 churches, that of St. Augusta attracting notice by its noble architecture, and its long noble staircase. Here are also two monasteries, and two nunneries. The inhabitants are industrious, and trade particularly

particularly in cloth, woollen and silk manufactures, and carry on an extensive commerce in wine, corn, and honey, both with the adjacent provinces and with Germany; 2 miles N. of Ceneda.

SERRE, I. A., in *Biography*, a miniature painter of Geneva, who had been in England, and seemed well acquainted with Gemmini, and the state of music in our country in the middle of the last century. He has analysed the "Guida Armonica" of Gemmini, the "Basse fondamentale" of Rameau, and the Treatises of Tartini, with his discovery of the "Terzo Suono." These celebrated works M. Serre has critically examined in two ingenious essays, published in 1753 and 1763, in which there are likewise many curious remarks on disputable points in the theory and practice of harmony, which will both amuse and instruct musical students.

SERRÉ, Fr., close intervals in music, such as the enharmonic quarter tones in the ancient Greek music; and in French music, short and quick. See SPICISSUS.

SERRE, La, in *Geography*, a river which runs into the Oise, near La Fere, in the department of the Aisne.

SERRE, a town of France, in the department of the Isere; 12 miles N. of Romans.

SERRES, JOHN DE, in *Biography*, a Protestant minister, was born in the south of France, and studied at Lausanne. We find him in 1572, serving a country church in the neighbourhood of Geneva. Having made himself known by various works, he became rector of the college of Nismes, and a minister of that city, and he was employed on several important occasions by Henry IV.; that prince having asked Serres if it were possible for a person to be saved in the communion of the church of Rome, he answered in the affirmative, whence he has been accused of promoting Henry's change of religion. Notwithstanding this decision, he was a warm controversialist against the Catholics, and made a very severe attack upon the Jesuits, entitled "Doctrinae Jesuiticæ precipua capita." As a learned author, he is chiefly known by an edition of Plato in three volumes folio, printed by Henry Stephens in 1578, with notes and a new Latin version, which however is not remarkable for correctness; and the style of those parts which Serres composed is very unequal to the majesty of the original. He was author of a number of works in history, and had the title of historiographer of France; but his compositions are said by the Catholics to be partial and full of misrepresentations. The principal of them are as follow; "Commentariorum de statu Religionis et Reipublicæ in Regno Franciæ," comprising the events from 1557 to 1576; "Memoire de la Troisième Guerre civile sous Charles IX.;" "Recueil des Choses memorables avenues en France sous Henri II., François II., Charles IX., et Henri III.;" and "Inventaire General de l'Histoire de France." Serres, towards the end of his life, engaged in the hopeless design of uniting the Catholic and reformed churches, which brought on him the contempt of one party and the enmity of the other. He died in 1598.

SERRES, OLIVIER DE, an eminent agriculturist, was born in 1539, at Villeneuve de Berg, in the Vivarais. During the civil tumults of his time, his property was pillaged, and his house demolished, and after it had been rebuilt, it was again destroyed by fire. He is said to have borne these misfortunes with great equanimity, and to have forgotten them by engaging his mind in study and rural occupations. By his talents he became so advantageously known to Henry IV., that he sent for him to Paris, and employed himself in several improvements about his domains. Serres wrote works, which rendered him the oracle of the cultivators in that age, and many of his ideas have been co-

pie'd by later writers without acknowledgment. The chief of these, in which he collected the results of long experience, is entitled "Theatre d'Agriculture, et Menage des Champs," 1600, and has been several times reprinted. It has been described by Haller as "a great and valuable work, written by an experienced man, fond of simplicity, and not at all attached to expensive methods." Some of the economical precepts of Mr. Serres have been thrown into verse, in order that they might be more easily remembered. He published treatises on the management of silk-worms, the collection of the silk, and the culture of the white mulberry-tree, which he introduced into France. This estimable man died in 1619, at the age of four-score, after having had the satisfaction of witnessing the happy effects of the improvements suggested by him.

SERRES, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap; 24 miles W.S.W. of Gap. The place contains 1219, and the canton 4249 inhabitants, on a territory of 170 kilometres, in 10 communes. N. lat. 44° 26'. E. long. 5° 8'.

SERRET, a town of Asiatic Turkey, in Natolia; 30 miles W. of Callamena.

SERRIERES, a town of France, in the department of the Ardèche, and chief place of a canton, in the district of Tournon; 15 miles N. of Tournon. The place contains 1924, and the canton 9416 inhabitants, on a territory of 115 kilometres, in 17 communes.

SERRIS, a town of Hindoostan, in Bahar; 15 miles S.E. of Saferam. N. lat. 24° 51'. E. long. 84° 26'.

SERRO, a small island belonging to the cluster of Papuan isles. See PAPUA.

SERROPALPUS, in *Entomology*, a genus of insects, of the order Coleoptera, whose generic character is as follows: antennæ fetaceous; four unequal feelers; the anterior ones are the longer, and deeply ferrate, composed of four joints, the last very large, truncate, compressed, peltiform; the posterior ones are subclavate; thorax margined, concealing the head, with a prominent angle on each side; the head is deflected; and the feet formed for digging. There are two

#### Species.

STRIATUS. The body of this insect is brown; the shells striate. It inhabits the island Runfale, and is described in the Stockholm Transactions for the year 1786; where it is said to be found chiefly on old wooden buildings, in the evening in autumn, and is about the size of the *Elater aterrimus*.

LÆVIGATUS. This species is characterized by a black body, and smooth shells. It inhabits different parts of Europe, and is likewise described in the volume of the Stockholm Transactions already referred to.

SERRURIA, in *Botany*, a name rightly altered by Mr. Sahlbary and Mr. Brown, from the *Serraria* of professor John Burmann, who, in his *Plantæ Aricænae*, 266, establishes the latter appellation, in honour of Dr. Joseph Serrurier, Professor of Botany at Utrecht; but it is not easy to discover the above author's meaning in thus perverting the word; for *Serrurier* is a locksmith, and has no reference to a law, or lawyer — Brown, *Fl. of Linn. Soc.* v. 10. 112. Art. Hort. F. w. v. 1. 198. Class and order, *Titrationis M. negypta*. Nat. Ord. *Aggregata*, Linn. *Protocæca*, Juss. Brown.

Fl. Ch. Corolla in four deep segments. Stamens in the concave tips of the segments. Nectary four scales beneath the

the germen. Stigma vertical, smooth. Nut superior, somewhat stalked. Common receptacle convex, many-flowered, with chaffy deciduous scales.

A genus of rigid Cape shrubs, of which Mr. Brown describes thirty-nine species, eight of which find a place in the Hortus Kewensis. The *leaves* are thread-shaped, pinnatifid or three-cleft, rarely undivided. Heads of *flowers* either terminal, or, from the bosoms of the uppermost leaves, either simple and solitary, or composed of several sessile partial heads, or corymbose. *Braçteas* imbricated, membranous, most commonly shorter than the *flowers*, in a few instances longer, in some wanting. *Flowers* always sessile, purple. *Pistil* the length of the corolla, with a club-shaped, rarely cylindrical, stigma. Nut oval, finely downy, sometimes bearded, sometimes nearly smooth. We select the following examples, among which are included all the species known in the gardens of England.

Sect. 1. *Heads simple; the flower-stalks undivided or wanting.*

*S. pinnata.* Wing-leaved Serruria. Brown. n. 8. Ait. n. 1. (Protea pinnata; Andr. Repof. t. 512.)—Heads stalked, somewhat aggregate. *Braçteas* lanceolate, villous, nearly as long as the flowers. Corolla bearded. Leaves pinnatifid or three-cleft, longer than the heads. Stem procumbent, hairy.—Gathered by Mr. Niven, on dry hills at the Cape of Good Hope, particularly in ascending Paarlberg. It flowered in Mr. Hibbert's garden, in the summer of 1807. In a natural state the stem is said to be perfectly prostrate, dividing from the base into branches about a foot long, round, downy, leafy. *Leaves* above an inch long, turned upwards, consisting of three or five awl-shaped segments. Heads of *flowers* red, about as big as a walnut, either solitary and terminal, or partly axillary; the young buds enveloped in the white silky hairs, which clothe the tips of the corolla externally.

*S. cyanoides.* Trifid-leaved Serruria. Brown. n. 10. Ait. n. 2. (Protea cyanoides; Linn. Mant. 188. Willd. Sp. Pl. v. 1. 507. Cyanus æthiopicus, rigidis capillaceis tenuissimis foliis trifidis; Pluk. Mant. 61. Phyt. t. 345. f. 6.)—Heads terminal, longer than their stalks. *Braçteas* roundish, pointed, villous. One segment of the corolla nearly smooth. Leaves spreading; the lower ones three-cleft; upper subdivided. Stem nearly upright.—Native of hills about the Cape. Mr. Brown gathered it on the sides of mountains, near Simon's bay. A shrub of humble growth, flowering with us in June or July. The *branches* are scarcely pubescent. *Leaves* not an inch long, rather hairy while young. *Flower-stalks* solitary, downy, generally but half the length of the heads of flowers, which are the size of a large cherry, rising above the upper leaves, and accompanied by membranous silky *braçteas*.

*S. pedunculata.* Woolly-headed Serruria. Brown. n. 13. Ait. n. 3. (Protea glomerata; Andr. Repof. t. 264.)—Heads terminal, stalked. *Braçteas* ovate, downy. Corolla curved, feathery; its inner segment silky. Leaves twice or thrice pinnatifid, hairy, as well as the upright stem.—Found in various hilly situations at the Cape of Good Hope, where the soil is rather fertile. Messrs. Lee and Kennedy are recorded as having first raised this species, in 1789, from seeds obtained from Vienna. It flowers in summer, and makes a handsome appearance, with its copious many-cleft *leaves*, and large heads of light reddish brown *flowers*, clothed with fine white plumy down. The *anthers* are yellow. Stigma blackish.

*S. hirsuta.* Hairy Serruria. Brown. n. 15. (Protea phlycoides; Thunb. Diff. n. 9. Prodr. 25. Willd. Sp. Pl. v. 1. 510, excluding the reference to Bergius.)—

Heads terminal, longer than their stalks. *Braçteas* linear-lanceolate, hairy. Corolla feathery. Leaves doubly pinnate, about as long as the heads. Branches hairy. Stem erect.—Native of itony hills at the Cape. Mr. Brown observed it near Simon's bay. It seems unknown in our gardens. This *shrub* is two or three feet high, with straight umbellate *branches*, rough with spreading permanent hairs. *Leaves* copious, moderately spreading, an inch, or sometimes an inch and half, long, hairy when young only; their segments very sharp-pointed. *Flower-stalks* often more than one at the top of each branch, half the length of the heads, with lanceolate-awl-shaped, spreading *braçteas*. Heads as big as a walnut, rising above the upper leaves. Corolla slightly curved; the hairs on its inner segment shorter than those of the other three. Stigma cylindrical, somewhat club-shaped.

*S. Niveni.* Niven's Serruria. Brown. n. 17. Ait. n. 4. (Protea decumbens; Andr. Repof. t. 349.)—Heads terminal, sessile. *Braçteas* lanceolate; the inner ones silky. Corolla bearded. Leaves doubly pinnatifid; the uppermost longer than the head, and smooth like the branches. Stem decumbent.—Discovered by Mr. James Niven, on Swartberg, a rocky mountain at the Cape of Good Hope, and sent by him to Mr. G. Hibbert in 1800. It blooms in the summer, and is of a small stature, and decumbent habit. The *flowers* are of a dull red, clothed externally with white silky hairs; and each solitary head, smaller than a hazel-nut, is encompassed with numerous, crowded, radiating *leaves*. Each leaf of the general foliage is about an inch long. Stigma hardly thicker than the style. Mr. Andrews's plate represents the *branches* as somewhat downy.

*S. phlycoides.* Phlyca-flowered Serruria. Brown. n. 24. Ait. n. 5. (Leucadendron phlycoides; Berg. Cap. 29. Protea sphaerocephala; Linn. Mant. 188. P. abrotanifolia; Andr. Repof. t. 507.)—Heads terminal or axillary, on scaly stalks. *Braçteas* half as long again as the head, lanceolate, smooth; the outer ones narrowest. Tips of the corolla bearded. Leaves twice compound, longer than the flower-stalks.—Native of the Cape, from whence it was sent to Kew, by Mr. Masson, in 1788; flowering there in July and August. This is a smooth upright *shrub*, with reddish leafy *branches*. *Leaves* generally bipinnatifid, an inch or two long, moderately spreading. The *flower-stalks*, clothed with several lanceolate scales, and either solitary, or aggregate in a corymbose manner, are longer than the heads, but usually shorter than the foliage. Heads above half an inch in diameter, subtended by many longish, deflexed, green, red-pointed *braçteas*. Corolla whitish and smooth, except the ends of the segments, which are red, and densely bearded. Stigma red, cylindrical.

*S. florida.* Large-flowered Serruria. Brown. n. 26. (Protea florida; Thunb. Diff. n. 2. t. 1. Prodr. 25. Willd. Sp. Pl. v. 1. 506.)—*Braçteas* longer than the stalked heads; the outer ones elliptic-oblong, pointed, smooth; inner concealed, linear-lanceolate, fringed. Leaves once or twice pinnatifid.—Thunberg and Masson gathered this species on the mountains of Franche Hoek at the Cape. It has not as yet found its way into our green-houses, which is much to be regretted, no other *Serruria* being comparable to it in beauty. The *leaves* are three or four inches long, smooth, as well as the *branches*, which are of a purple hue. *Flowers* many together, on corymbose scaly stalks at the ends of the branches, large, remarkable for their beautiful red external *braçteas*, which are each an inch or inch and half long, attended by smaller ones, of the same kind, feathered down the stalk, while the innermost *braçteas*, coming into view by the spreading of the former, are linear, fringed with

with yellow hairs. This is a very rare plant, even in dried collections.

SECT. 2. *Heads compound; partial ones crowded.*

*S. decumbens.* Trailing Serruria. Brown. n. 27. (Protea decumbens; Thunb. Diff. n. 1. t. 1. Prodr. 25. Willd. Sp. Pl. v. 1. 506. *P. procumbens*; Linn. Suppl. 116.)—Stem prostrate, smooth, as well as the three-cleft leaves, whose segments are undivided. Each partial head of about four flowers.—Native of the stony sides of mountains, at the Cape of Good Hope; not as yet known as a garden plant. It is smooth, dividing from the root into several prostrate, leafy, wavy branches. Leaves ascending, about two inches long, in two or three simple, thickish, linear segments. Flower-stalks axillary and terminal, slender, scaly, each bearing a small roundish head, enveloped in ovate, pointed, rather silky bractees, and composed of from four to six smaller heads. Corolla silky, very slightly curved. Mr. Brown remarks that some of the heads are, apparently from starvation or abortion, simple.

*S. glomerata.* Many-headed Serruria. Brown. n. 31. Ait. n. 6. (Protea glomerata; Linn. Mant. 187. Willd. Sp. Pl. v. 1. 509. Leucadendron glomeratum; Linn. Sp. Pl. 137. Serraria foliis tenuissimè divisis, capitibus tomentosis; Burm. Afr. 265. t. 99. f. 2.)—Stem erect, smooth like the doubly pinnatifid leaves. Partial heads of many flowers. Inner bractees somewhat silky. Common flower-stalks scaly. Stigma club-shaped.—Found in stony hilly places at the Cape. Mr. Masson is said to have sent it, about the year 1789, to Kew, where it flowers in July and August. A rather humble shrub, with reddish branches. Leaves from one to two inches long, slender, quite smooth. Flower-stalks downy; the common ones often aggregate and racemose, clothed with broad, smooth, loosely imbricated, scaly bractees; partial ones shorter than their respective heads. Corolla externally silky.

SECT. 3. *Flower stalks divided. Heads simple, corymbose or racemose.*

*S. Burmanni.* Burmann's Serruria. Brown. n. 36. Ait. n. 7. (Protea Serraria; Linn. Mant. 188. Willd. Sp. Pl. v. 1. 508. Leucadendron Serraria  $\varnothing$ ; Linn. Sp. Pl. 137. Serraria foliis tenuissimè divisis, floribus rubris apetalis; Burm. Afr. 264. t. 99. f. 1. Abrotanoides arborescens, &c.; Pluk. Mant. 1. Phyt. t. 329. f. 1.)—Heads corymbose, each of about ten flowers. Corollas level-topped, more or less silky, shorter than the partial stalks. Leaves doubly pinnatifid, brittle-shaped, longer than the flower-stalks.—Native of low barren spots, about the sides of hills at the Cape, very frequent. Mr. Masson sent it in 1786 to Kew garden, where it blossoms from May to July. A humble corymbose shrub, with very slender acute leaves, which are slightly hairy. The heads are small, reddish, crowned with the long prominent styles. Mr. Brown mentions a variety, or possibly distinct species, whose leaves are rather silky, heads more obtuse at their base, and bractees, as well as flowers, altogether silky.

*S. triternata.* Silvery-flowered Serruria. Brown. n. 37. Ait. n. 8. (Protea triternata; Thunb. Diff. n. 7. Prodr. 25. Willd. Sp. Pl. v. 1. 509. *P. argentiflora*; Andr. Repof. t. 447.)—Corymb compound. Heads globose, many-flowered. Bractees and partial flower-stalks silky. Leaves thrice ternate, smooth as well as the stem.—Gathered by Mr. Niven, near the river at Roode Zant, Cape of Good Hope. Messrs. Lee and Kennedy are said to have first raised this elegant species, about the year 1802. It blossoms from June to August. The leaves are four or five inches long, and as thick as a crow's quill, being larger, as well as more compound, than in most other species. Heads

of flowers of a silvery white, silky, numerous, each rather above half an inch diameter. Stigma obovate, yellow.

SERSALISIA, so named after a Neapolitan ecclesiastic, much commended by Fabius Columna, (though in what part of his writings we are not informed,) is a genus separated by Mr. Brown, in his Prodr. Nov. Holl. v. 1. 529, from the Linnæan *Sideroxylon*; but the character does not seem to us very clear. One species of this new genus is *Sideroxylon fericeum*, Ait. Hort. Kew. ed. 1. v. 1. 262. ed. 2. v. 2. 13; another is called by Mr. Brown *Sersalisia obovata*. Both are natives of the tropical parts of New Holland. See SAPOTÆ and SIDEROXYLON.

SERSEY, in *Geography*, a town of Hindooistan, in Oude; 25 miles E. of Baraich.

SERTA, GARLANDS, among the *Ancients*. See GARLAND.

SERTAM, in *Geography*, a town of Portugal, on the river Pera, in Estremadura; 24 miles N.E. of Thomar.

SERTINO, a river of Sicily, which runs into the sea, on the east coast.

SERTORIUS, QUINTUS, in *Biography*, a distinguished Roman commander, was a native of Nursia, in the Picentine regions of Italy. His father died in his infancy, but by the care of his mother he received a most excellent education; and even in his youth he gained a considerable reputation as a pleader at Rome. He had, however, a decided turn for the duties and glory attached to a military life, and made his first campaign under Servilius Cæpio, against the Cimbrians and Teutones in Gaul. In an early engagement he was severely wounded, and would have lost his life, if he had not possessed sufficient vigour to swim across the Rhone, when encumbered with his armour. He next served under Marius, and exhibited proofs of valour and talents, which much ingratiated him with that general. Spain was the next great theatre of his exertions, where he served under Didius, and acquired much reputation in the campaign. On his return to Rome, he was made questor in Cisalpine Gaul; and when the social war broke out, he brought a well-timed reinforcement to the Roman army. In a battle that ensued, he lost an eye, a mark of bravery in which he always gloried, and which pointed him out to the plaudits of the people, whenever he appeared in the theatre, and other public places. He was candidate for the tribuneship, but was disappointed in his hopes by the overbearing interest of Sylla: he accordingly joined the party of Marius in the succeeding civil war. He commanded one of the three armies which invested Rome, and honourably distinguished himself by abstaining from all those acts of cruelty which disgraced the arms of Cinna and Marius. When Sylla gained the ascendancy in Italy, Sertorius withdrew to Spain, of which country he had been appointed pretor. Here he hoped to be able to revive his cause, and with this view he detached a body of troops to seize the passes of the Pyrenees; but the murder of their commander induced them to abandon their post, and consequently laid Spain open to Sylla's officers. After some various adventures, chiefly of the disastrous kind, Sertorius went into Africa, and assisted the Mauritians to throw off the yoke of a tyrannical king; defeating one of Sylla's generals, by whom he was supported. His reputation now caused him to be invited to Lusitania; and sailing thither with a small body of Romans and Africans, he obtained such an ascendancy over the natives, that he soon had the command of the whole Lusitanian nation. He exercised them in the arts of warfare, and introduced a rigid discipline among them; but Roman tactics being unsuitable to them, he adopted a service better suited to the nature and circumstances

stances of the country. He defeated, with his new-trained armies, several Roman generals, who were sent against him, and instituted a senate in competition with that of Rome, and imitated all the forms of the republic. He foiled the attempts of that eminent commander, Metellus, to reduce him; continually harassing his troops by sudden attacks and skirmishes, and intercepting his convoys. He adopted the liberal policy of civilizing the Lusitanians and neighbouring Spaniards, and familiarizing them with Roman letters and customs. For this purpose he established a great school in the city of Oſca, at which the sons of men of distinction were gratuitously educated, and at the same time kept as hostages for the fidelity of their parents. Feeling that his power was not sufficiently firm, without the aid of superstition, which ever captivates the ignorant and uncivilized, he trained a white fawn, that had been presented to him, to such a degree of tameness, that it followed him whithersoever he went, and was his constant companion; and he encouraged the belief that the animal was the gift of Diana, and intended by that goddess to convey him information of the designs of his enemies. At length the famous Pompey was nominated to the command against him; and when he arrived, he found that all the Roman troops, which, after the death of Lepidus, had been carried to Spain by Perſenna, with the design of setting up there for himself, had joined Sertorius, who was now at the head of a considerable army. Pompey proceeded against him with a superior force; but Sertorius took a town in his presence, and afterwards defeated him at the battle of Sucro. He gave him a second defeat; but Metellus routed a separate division, and Sertorius was glad to take to the mountains. He then offered to lay down his arms, provided the proscription against him might be taken off, and he were permitted to return to Rome. Soon after he received an embassy from Mithridates, the formidable foe of the Romans, offering him an advantageous alliance, provided he were suffered to repossess the provinces from which he had been expelled by Sylla. But Sertorius would not agree to more than his recovery of Bithynia and Cappadocia, without touching upon the Roman province of Asia; and upon these terms the treaty was concluded. A conspiracy was formed against Sertorius by the Roman patricians in his army, and they succeeded in exciting a revolt in several Lusitanian towns. Incensed at this defection, he caused several of the children, whom he kept as hostages at Oſca, to be slain, and others to be sold as slaves. This is said to have been the only act of cruelty by which his memory is tarnished. In revenge for the loss of their sons, the conspirators formed a plot against the life of Sertorius; in consequence of which he was safely assassinated, while he was at a feast. This event took place in the year 73 B.C. "The great qualities and military talents of this eminent person would undoubtedly have raised him to the first rank among the chiefs of his country, had he not been a leader of a party, instead of a commander for the state. With nothing to support him but the resources of his own mind, he created a powerful kingdom among strangers, and defended it a long time against the arms of Rome, although wielded by the ablest generals of his time; and he displayed public and private virtues, which would have rendered a people happy under his rule at a less turbulent period." Univer. Hist.

**SERTULA CAMPANA**, in *Botany*, a name given by some authors to melilot.

**SERTULARIA**, in *Natural History*, a genus of the class Vermes, and order Zoophytes. The generic character is this: the animal grows in the form of a plant; the stem is branched, producing polypes from cup-shaped den-

ticles, or minute cells. There are nearly four-score species, divided into two sections, A and B, of which the following is the description.

A. *Stem horny, tubular, fixed to the base, beset with cup-shaped denticles, and furnished with vesicles, or ovaries, containing polypes, eggs, or living young.*

Species.

\* **ROSACEA**. This species is panicled, with opposite, tubular, truncate denticles, and alternate branches; the vesicles are crowned with spines. It inhabits the European seas, and our own coasts, growing on shells, or creeping up other corallines; it is white; the vesicles resemble the blossom of the pomegranate.

\* **PUMILA**. The denticles of this species are opposite, pointed, and recurved; the vesicles are obovate; the branches loose and irregular. It is found in the ocean, on fuci, particularly on the ferratus.

\* **OPERCULATA**. Denticles opposite, pointed, and nearly erect; the vesicles are obovate, covered with a lid; the branches are alternate. It inhabits the European and American seas, on fuci and shells. The twigs are about five inches long; the denticles are bicuspidate, with a short bristle on each side.

\* **TAMARISCA**. Denticles nearly opposite, truncate, three-toothed; vesicles ovate, two-toothed, with a short tube in the centre; the branches are alternate. This is found in most of the European seas, and is the largest of its kind. It is about four inches long, and is found adhering to shells.

\* **ABIETINA**. Denticles nearly opposite, tubular, oval; the vesicles are oval, and the branches alternate. It is found in the British and other European seas, and the Mediterranean, growing to shells. It is five inches long, and often covered with small serpulæ; the branches are frequently pinnate.

\* **NIGRA**. Denticles nearly opposite, minute; vesicles large, placed all on one side, oval, quadrangular; the branches are pinnate. This is found on the Cornish coast, adhering to the *Mytilus margaritifera*. It is four inches long, blackish.

\* **FUSCESCENS**. Denticles nearly opposite, tubular; the vesicles are numerous, placed all on one side, minute, with three tubercles on each; the branches are pinnate. This is also an inhabitant of the Cornish coast. It resembles the last, but is of a greyish-brown colour.

**OBSOLETA**. Denticles generally placed in eight rows, ovate, slightly heart-shaped, and disposed in a quincunx form; the branches are alternate and pinnate. It is an inhabitant of the Frozen ocean, is about five inches high, and of a horn colour, with the joints becoming more and more obsolete towards the top.

**PINUS**. Denticles sub-spinous, generally disposed in six rows; the vesicles are bottle-shaped, turgid, subdiaphanous, with a simple mouth; the branches are pinnate, nearly alternate. It inhabits the White sea, fixed to shells.

**CUPRESSOIDES**. Denticles simple, obliquely truncate, with a slightly protuberant mouth; the vesicles are ovate, with a subtubular mouth; the branches are dichotomous, loose, and with the trunk joined with two rings at the junctures. This is found in the White sea; is subdiaphanous, yellowish, and nearly half a foot long.

\* **CUPRESSINA**. Denticles nearly opposite, obliquely truncate, and a little pointed; vesicles obovate, two-toothed; branches panicled, and very long. It is common in all the European seas, and is found in a long pointed loose panicle.

\* **ARGENTEA**.

## SERTULARIA.

\* **ARGENTEA.** Denticles nearly opposite, pointed; vesicles oval; branches alternate, panicled. This is an inhabitant of the European and American seas; very much resembles the last, but the branches are shorter and looser, and the panicle is more obtuse.

\* **RUGOSA.** Denticles nearly opposite, obsolete; vesicles much wrinkled, and three-toothed; the branches are scattered. This species inhabits the European seas, and is found growing on the *Flustra foliacea*, and other *sertularia*.

\* **HALECINA.** Denticles alternate, tubular, and two-jointed; the vesicles oval, each united along the side to a small tubular stalk; the stem is alternately branched and pinnate. This is found in the European and Mediterranean seas. It is horny, and of a yellowish-grey; the denticles are nearly obsolete.

\* **THUJA.** The denticles in this species are arranged in two rows, closely adhering to the stem; the vesicles obovate, margined; stem waved and stiff, with a tuft of dichotomous branches near the tip. It is found on the northern coasts of England, and in the Mediterranean, and is about half a foot long.

\* **MYRIOPHYLLUM.** The denticles are truncate, all leaning one way on the stem; the stem itself is gibbous on the side opposite the branches; the branches lean all one way. This is found in most European seas, and in the Mediterranean; it is about three inches long, is pale and horny; the stem is rather angular, with arched protuberances opposite the branches; the denticles are seated in a socket furnished with a short spine on the lower part.

**HYPNOIDES.** Denticles pointing one way, campanulate, toothed, and beaked; stems with pinnate branches, and very crowded subdivisions. It inhabits the Indian ocean, is six inches high; in colour it is brown, with yellowish imbricate radicles.

**SPECIOSA.** Denticles campanulate, effuse, toothed, and stipulate; the stem is pinnate, rigid, with incurved branches, mostly pointing one way. It is found in the Indian ocean, adhering to the tubular radicles of *gorgonia*; it is brown, horny, and from three to four inches long.

\* **FALCATA.** The denticles of this species point all one way; they are imbricate and truncate; the vesicles are ovate; the branches are pinnate and alternate. There is a variety of this species described by Ellis, in his work on *Corallines*. It inhabits the European and Indian seas, and is from three inches to a foot long; the stem is a little flexuous; the denticles in a single row.

\* **PLUMA.** In this the denticles point one way, they are imbricate and campanulate; the vesicles are gibbous and crested; the branches are pinnate, alternate, and lanceolate. It is found on most European coasts, climbing up fuci; the branches are jointed; the denticles are serrate at the margin, and supported in front by a small hollow spine; the vesicles have a denticulate margin, and generally five oblique crested ribs.

**ECHINATA.** Denticles opposite, pointing one way, campanulate; the vesicles are crested; the branches pinnate, alternate, and lanceolate. It inhabits chiefly the shores of Sweden, on fuci.

\* **ANTENNINA.** The denticles are verticillate, in fours, fetaceous; vesicles obliquely truncate, verticillate; the stems are generally simple. There is a variety which is branched. They are both found on the British coasts, often nearly a foot high; it is yellow, with very fine capillary yellowish radicles; the stem is surrounded with small incurved fetaceous branches, on the upper sides of which are rows of small cup-shaped denticles; the vesicles are placed

on pedicles obliquely open towards the stem, and placed round it at the insertion of the branches.

\* **VERTICILLATA.** The denticles in this are obsolete; the vesicles campanulate, toothed round the rim, on long twisted pedicles, and placed in fours round the stem; the branches are alternate. It is found on the British coasts; stem ribbed, very loosely branched; the denticles are not visible; the vesicles are nearly erect, and glutinous; the ovaries are oval, ending in a tubular mouth.

**GELATINOSA.** Vesicles campanulate; stem with numerous decomposite spreading branches. It is found on the coasts of the Netherlands; is half a foot long, and of a greyish-brown colour.

\* **VOLUBILIS.** The denticles in this are obsolete; the vesicles are alternate, campanulate, toothed round the rim, on long, twisted pedicles; the branches are alternate. It inhabits European seas, climbing up other *sertularia*; it is whitish and minute; the stem is loosely branched; the ovaries are egg-shaped and smooth, or transversely wrinkled.

\* **SYRINGA.** Denticles obsolete; vesicles cylindrical, mostly alternate, and placed on short twisted pedicles.

\* **CUSCATA.** Denticles obsolete; vesicles oval, axillary; branches opposite and simple. It is found in the European seas, adhering to fuci.

\* **PUSTULOSA.** Stem with alternate dichotomous branches, obsoletely denticulate on the upper part. It inhabits the shores of the Isle of Wight, and is four inches long. The stem is seen rising into alternate dichotomous joints, with small denticles, having a circular rim, with a point in the middle of each towards the upper part of each joint.

\* **FRUTESCENS.** Denticles cylindrical, campanulate, placed in a single row on the inside of the branches; the branches are alternate, and pinnate. This is chiefly found on the British shores; rather hard, blackish with brown branches; the stem is composed of small united tubes.

**PINASTER.** In this species the denticles are opposite, sessile, with an incurved tubular tip; the vesicles are large, ovate, quadrangular; the angles terminating in a spine, and furnished with a tubular mouth in the centre, placed in a row along the branches; the branches are alternate.

**PENNATULA.** The denticles in this are in a single row, crenate on the rim, and supported by a slender, truncate, incurved horn; the branches are opposite. It is found in the Indian ocean; is five or six inches long; yellowish-brown; the denticles have two opposite spines on the rim.

\* **FILICULA.** Denticles opposite, ovate, with a single erect one at the junctures of the branches; vesicles obovate, with a tubular mouth in the centre; the stem is zig-zag, with alternate branches. It inhabits the British shores, is very tender, and the stem is much branched.

**QUADRIDENTATA.** Denticles in fours, opposite, at the joints of the stem; the stem is simple, with the joints tapering and twisted towards the base. It inhabits the African shores on the *Fucus lendigerus*.

**SPICATA.** Denticles in three, cylindrical, terminal, and nearly closed at the mouth; vesicles ovate, axillary; stem tubular, panicled, annulate, with trichotomous branches disposed in whorls round the rings.

\* **EVANSII.** The denticles are short and opposite; the vesicles are lobed, arising from the branches which are opposite. It inhabits the British coasts, and is found on fuci; it is two inches high, very slender, and yellow, with fulvous vesicles.

\* **MURICATA.** The denticles of this species are pedicled, proceeding alternately from the joints of the branches; vesicles oval, spinous; the stem is jointed. It is found on the shores of Scotland; the vesicles are nearly globular,

# SERTULARIA.

placed on pedicles, and full of pointed spines from crested ribs.

**SECUNDARIA.** Denticles in a single row, campanulate; the vesicles are axillary; the stem is minute, white, and incurved. This species is found in the Mediterranean; it is scarcely three lines high, and not thicker than a fine brittle.

**MISENENSIS.** The denticles are alternate, very thin, spreading; the vesicles are oval, peduncles axillary; stem much branched, dichotomous. It inhabits the Mediterranean, is very slender, pellucid towards the tip, and sometimes covered with the Cancer linearis.

**RACEMOSA.** Denticles scattered, pellucid; vesicles clustered; stem straight, round; opaque, horny, with slightly curved branches. It inhabits the Mediterranean.

\* **UVA.** Denticles obsolete; vesicles ovate, clustered; stem slightly branched, with alternate subdivisions. It inhabits the shores of this country and Holland, adhering to other zoophytes; vesicles transparent, with a white nucleus.

\* **LENDIGERA.** Denticles obsolete; vesicles cylindrical, arranged in a single row along the branches, and growing gradually less towards the top: the stem and branches are jointed. This is found on the European coasts, on other zoophytes. The branches are subdivided and irregularly interwoven; the vesicles are placed in parallel ranks along the inside of the branches, and growing gradually shorter towards the top of the joints.

\* **GENICULATA.** Denticles alternate, twisted; vesicles obovate, with a tubular mouth in the centre; the stem is branched, jointed, flexuous. It inhabits the European coasts, adhering to fuci.

\* **DICHOTOMA.** Denticles obsolete; vesicles obovate and axillary, on twisted pedicles; the stem is dichotomous, with twisted joints. It inhabits the British and Dutch coasts, and is nearly a foot long; it is white, but becomes testaceous with age.

\* **SPINOSA.** Denticles obsolete; vesicles ovate, subulate; the branches are dichotomous and spinous. It is found on most European coasts, as well as on those of this country, and is about eight inches long. The stem is composed of interwoven tubular fibres; the branches are flexuous, loose, forked, with pointed tips.

\* **PINNATA.** The denticles of this species are obsolete; the vesicles are oblong, and surrounded with a coronet of tubercles at the rim; stem simple, pinnate, and lanceolate. It is found in Europe and in India, and is about three inches high. The stem is simple, with alternate subdivisions; the vesicles are placed in clusters round the stem.

\* **SETACEA.** Denticles obsolete, remote, placed in a row on the upper side of the branches; vesicles oblong, axillary; the stem is simple, with alternate bent divisions. It inhabits the European coasts, and is about an inch and half high.

\* **POLYZONIAS.** Denticles alternate, slightly toothed; vesicles obovate, transversely wrinkled; the stem is loose, branched. It inhabits most seas, adhering to marine substances.

**PENNARIA.** The denticles are placed in a row on one side the branches; the vesicles are oval; the stem is twisted, and doubly pinnate. It inhabits the Mediterranean sea, growing in tufts on rocks; the stem is straight, ascending, flexile, horny, brown with whitish branches.

\* **LICHENASTRUM.** Denticles alternate, obtuse, in two imbricate rows along the stem; the vesicles are ovate, in two parallel rows along the branches; the stem is simple, alternately pinnate. It is found in the Irish, Indian, Asiatic, and

Armenian seas. The stem is erect, jointed, compressed, and denticulate; the branches are alternate, denticulate, and straight.

**CEDRINA.** Denticles subcylindrical, tubular, in four imbricate rows; the branches are irregular, quadrangular, and thicker upwards. Inhabits the seas of Kamtschatka; the branches are dichotomous, obtuse, with four rows of vesicles.

\* **IMBRICATA.** The vesicles of this species are subclavate, irregularly imbricate upwards; the stem is slightly branched. This species is described and figured in the 5th vol. of the Linnæan Transactions. It inhabits the western coast of Britain, on the Fucus nodosus; it very much resembles the last, but the vesicles are not placed in any regular series; it is about three inches high; the smaller branches have the vesicles placed bifariouly, but towards the tip they become imbricate.

**PURPUREA.** Denticles subovate, tubular, in four imbricate rows; the vesicles are erect and campanulate; the branches are dichotomous and square. It inhabits the sea round Kamtschatka, and is of a blackish-purple.

**ARTICULATA.** Denticles pressed together; the vesicles are ovate, rather large, covered with a lid, and placed in a single row; the stem is jointed and pinnate. It is found in the Atlantic ocean, creeping on shells, and is about two inches long; pale yellow.

**FILICINA.** Denticles imbricate, placed on one side only; vesicles jointed; stem granulate, branched and pinnate, the subdivisions alternate. It inhabits the Indian ocean, is pale, and about three inches long.

**FRUTICANS.** The denticles of this species are in a single row on one side; semi-campanulate; the stem is granulate, woody, with alternate setaceous subdivisions. It inhabits the American seas in tufts, on shells: it is six inches long, and of a yellowish-grey.

B. *The species of this division have a crustaceous stem, inclining to stone, and composed of rows of cells; they have no vesicles, but in the place of these there are small globules.*

\* **BURSARIA.** Denticles opposite, compressed and truncate; the stem is branched, and dichotomous. It is found on the British coasts, adhering to fuci; it is minute, flexile, hyaline; the denticles are carinate, with a small clavate tube at the top.

\* **LORICULATA.** Denticles opposite, obliquely truncate, and nearly obsolete; the branches are erect and dichotomous. It inhabits the British coasts, on old fertularia.

\* **FASTIGIATA.** Denticles alternate, pointed; branches dichotomous, erect. This is found in the British seas; the denticles are marked with a black spot in the middle.

\* **ARICULARIA.** The denticles all point one way, nearly opposite, and furnished with two mucronate appendages; the globules appendaged; the stem is branched and dichotomous. It is found in the European seas; is from one to two inches long; in colour it is of a dirty grey. It is very brittle.

\* **NERITINA.** The denticles are alternate, acute, and pointing one way; the branches are dichotomous, unequal, and straight. It is found in the European and American seas. It is soft; the globules have an opening surrounded by a dark-coloured margin.

\* **SCRUPOSA.** Denticles alternate, angular, spinous; the branches are dichotomous and creeping. It inhabits most seas; is very brittle, linear, and pale, with a double row of cells.

**PILOSA.** The denticles are alternate, oblique, with a long mouth; the branches are dichotomous, fastigate, and strong.

strong. It is found in the Mediterranean, and is not half an inch long.

**CRISPA.** This species is very much branched, dichotomous, elongated, and crisp, with depressed ovate joints, furnished with cells on one side. It inhabits the East, is large, flexible, and of a pale-grey colour.

**FLOCCOSA.** This is very much branched, dichotomous, fastigiate, with wedge-shaped joints, having cells on one side. This is found chiefly in the Indian ocean; is large, whitish, with greyish flexible joints.

\* **REPTANS.** Denticles alternate, two-toothed; the branches are dichotomous and creeping. This is found in the European seas, adhering to the *Fultra foliacea*; it is not an inch long; white or pale-grey.

**PARASITICA.** The denticles of this species are verticillate, turbinate, ciliate, and parasitical. It is found in the Mediterranean and North seas, adhering to other fertulariæ and corallines; in colour it is dull red, with terminal denticles.

\* **CILIATA.** Denticles alternate, ciliate, funnel-form; branches dichotomous and erect. It inhabits the European seas, on marine substances; not half an inch high; it is whitish; the cells have wide mouths.

\* **EBURNEA.** The denticles are alternate, truncate, a little prominent; the vesicles are gibbous, with a tubular beak on one side; the branches spreading. This inhabits the European and Mediterranean seas, and is found growing upon other fertulariæ and fuci; is about an inch high, and white.

\* **CORNUTA.** The denticles are alternate and truncate, with a single hair on the top of each; the vesicles are gibbous, with a tubular beak; the branches are alternate. This inhabits, like the last and two following, the European and Mediterranean seas, on fuci; it is stony, clear white, and not half an inch long. The denticles are curved, tapering towards the base, and placed on each other.

**LORICATA.** Denticles in a concatenate row, pointing one way, with a margined mouth, horned beneath; the branches are alternate. It is found on fuci. The denticles are like inverted horns placed on each other, with a short hair on the top.

\* **ANGUINA.** The stem is very simple, without denticles, but beset with very simple, obtuse, clavate arms, each with a lateral opening. This is found climbing up marine substances; it is white, soft, flexible, varying in form, and appears to connect the fertulariæ and hydræ; the arms are testaceous.

**CEREOIDES.** Denticles imbricate, with somewhat prominent mouths; the stem is branched, jointed, and cylindrical. It inhabits the coast of Africa; is three inches high; whitish, stony, aggregate, with short joints.

**TULIPIFERA.** Cells in threes on the upper part of the joints, and united together; stem branched, with clavate joints. It inhabits the West Indies, adhering to fuci, about half an inch high, and clear white; the stem is stony and subdiaphanous; the cells are terminal.

**FLAELLUM.** This species is stony, branched, jointed, dichotomous; the joints are somewhat wedge-shaped, and have cells on one side. It inhabits the Bahama islands, is about two inches high, white, growing in tufts; the joints are convex and striate on one side; the others are flat, with a triple row of cells.

\* **TERNATA.** Branched, dichotomous, jointed, creeping; the joints are angular at their sides, with three cells in the front of each. It inhabits the shores of Scotland; it is stony, semitransparent.

**CIRRATA.** Stony, jointed, flat, dichotomous, incurved,

the joints are subciliate, ovate, truncate, flat, and having cells on one side. It inhabits the Indian ocean, is about two inches high, and is white; the joints are convex, and striate on one surface; the other is flattened, with a double row of cells.

**OPUNTIOIDES.** Branches in threes, with cylindrical joints, covered with slightly prominent pores. It inhabits the Eastern ocean; is about half an inch high, erect, very much branched, white, stony, with the pores disposed in a quincunx form.

**SERVA,** in *Geography*, a town of Persia, in Segestan; 180 miles S.S.W. from Zareng.

**SERVAGE.** See **SERVICE.**

**SERVAL,** in *Zoology.* See **FELIS Serval.**

**SERVAN,** in *Geography*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of St. Malo. The place contains 8836, and the canton 10,617 inhabitants, on a territory of 50 kilometres, in 4 communes.

**SERVANDONI, JOHN NICHOLAS,** in *Biography*, an eminent architect, was born at Florence in 1695. He was employed by several of the sovereigns in Europe on occasions of magnificent public spectacles, in which he displayed a very fertile invention, with nobleness of ideas, and a correct taste. At Paris he had the direction of the theatre during 18 years, and was architect, painter, and decorator to the king; and was admitted member of the several academies of arts. He gave a number of designs for the theatres of Dresden and London, and was sent for to the latter capital on the rejoicings for peace in 1749. He presided at the grand festivals exhibited at the court of Vienna, on the marriage of the archduke Joseph and the princess of Parma. The king of Portugal frequently employed him, and honoured him with the order of Christ. He died at Paris in 1766, having acquired the reputation of being the first artist of the period in which he flourished. As an architect he has left a fine specimen of his taste in the portico and front of the church of St. Sulpice.

**SERVANT, SERVUS,** a term of relation, signifying a person who owes and pays a limited obedience for a certain time to another, in quality of master; in contradistinction to *slave*, over whose life and fortune the master claims an absolute and unlimited power. See **SLAVE.**

The first sort of servants, acknowledged by the laws of England, comprehends *menial* servants; so called from being *intra mania*, or *domestics*. The contract between them and their masters arises upon the hiring; if the hiring be general, without any particular time limited, the law construes it to be hiring for a year (Co. Litt. 42. F. N. B. 168.); but the contract may be made for any larger or smaller term. All single men between twelve years of age and sixty, and married ones under thirty years of age; and all single women between twelve and forty, not having any visible livelihood, are compellable by two justices to go out to service in husbandry, or certain specific trades, for the promotion of honest industry; and no master can put away his servant, or servant leave his master after being so retained, either before or at the end of his term, without a quarter's warning, unless upon reasonable cause, to be allowed by a justice of the peace (stat. 5 Eliz. c. 4.); but they may part by consent, or make a special bargain.

Another species of servants includes those called *apprentices* (which see): a third sort belongs to that class denominated labourers. See **LABOUR** and **LABOURERS.**

And there is a fourth species, if they may be called servants, being rather in a superior capacity of service; such as stewards, factors, and bailiffs, whom, however, the law

considers as servants *pro tempore*, with regard to such of their acts as affect their master's or employer's property. The treatment of servants, strictly so called, as to diet, discipline, and accommodation, the kind and quantity of work to be required of them, the intermission, liberty, and indulgence to be allowed them, must in a great measure be determined by custom; for the contract between them and their masters expresses only a few of a considerable variety of particulars which it is supposed to comprehend. A servant is not bound to obey the unlawful commands of his master; *e. g.* to minister to his unlawful pleasures; or to assist him by unlawful practices in his profession. For the servant is bound by nothing but his own promise; and the obligation of a promise extends not to things unlawful. For the same reasons, the master's authority is no justification of the servant in doing wrong; for the servant's own promise, upon which that authority is founded, would be none. A master may by law correct his apprentice for negligence, or other misbehaviour, provided it be done with moderation; though if the master or master's wife beat any other servant of full age, it is good cause of departure: but if any servant, workman, or labourer, assaults his master or dame, he shall suffer one year's imprisonment, and other open corporal punishment, not extending to life or limb. (5 Eliz. c. 4.) By service, all servants and labourers, except apprentices, become intitled to wages; according to their agreement, if menial servants; or according to the appointment of the sheriff or sessions, if labourers or servants in husbandry. For to them only the statutes for regulation of wages extend.

A master may maintain, *i. e.* abet or assist his servant in any action at law against a stranger; he may also bring an action against any man for beating or maiming his servant, assigning his damage by the loss of service, and proving the loss upon the trial; he may likewise justify an assault in defence of his servant, and a servant in defence of his master (2 Roll. Abr. 546.): and if any person hire or retain my servant, being in my service, I may have an action for damages against both the new master and the servant, or either of them; but if the master did not know that he is my servant, no action lies, unless he afterwards refuse to restore him upon information and demand. F. N. B. 167, 168.

As for those things which a servant may do in behalf of his master, they seem to be grounded on this principle, that the master is answerable for the act of his servant, if done by his command, either expressly given or implied; therefore, if the servant commit a trespass by the command or encouragement of his master, the master shall be guilty of it: if any inn-keeper's servants rob his guests, the master is bound to restitution (Noy's Max. c. 43.); and if the drawer at a tavern sells a man bad wine, by which his health is injured, he may bring an action against the master. (1 Roll. Abr. 95.) In the same manner, whatever a servant is permitted to do in the usual course of his business, is equivalent to a general command; if I pay money to a banker's servant, the banker is answerable for it; if a steward lets lease of a farm without the owner's knowledge, the owner must stand to the bargain: a wife, friend, or relation, that used to transact business for a man, are *quoad hoc* his servants, and the principal must answer for their conduct. Farther, if a servant, by his negligence, does any damage to a stranger, the master shall answer for his neglect: if a smith's servant lames a horse while he is shoeing him, an action lies against the master and not against the servant. A master is chargeable if any of his family layeth or carrieth any thing out of his house into the street, or common

high way, to the damage of an individual, or the common nuisance of his majesty's liege people. In case of fire the servant is accountable. Blackst. Comm. book i. See LARCENY.

Much depends upon the sobriety, integrity, and diligence of servants; and the ease with which they obtain characters, or procure employment with such characters, real or fictitious, as they gain, is very injurious both to their employers and to themselves. Characters are given with so little reserve and veracity, "that I should as soon depend," says the author of the Rambler, "upon an acquittal at the Old Bailey, by way of recommendation of a servant's honesty, as upon one of these characters." At the same time another extreme should be avoided, which is that of obstructing the advancement of a faithful and deserving servant, either from resentment, caprice, or self-interest. In order to form good servants, attention should be paid to their domestic conduct, and that kind of discipline should be exercised at home which may contribute to prevent their corruption and misery.

What the Christian scriptures have delivered concerning the relation and reciprocal duties of masters and servants, breathes a spirit of liberality, very little known in ages when servitude was slavery; and which flowed from a habit of contemplating mankind under the common relation in which they stand to their Creator, and with respect to their interest in another existence. (Ephes. vi. 5—9.) "Servants be obedient to them that are your masters, according to the flesh, with fear and trembling; in singleness of your heart, as unto Christ; not with eye-service, as men-pleasers, but as the servants of Christ, doing the will of God from the heart; *with good will, doing service as to the Lord, and not to men*: knowing that whatsoever good thing any man doth, the same shall he receive of the Lord, whether he be bond or free. And ye masters do the same thing unto them, forbearing threatening; knowing that your master also is in heaven; neither is there respect of persons with him." The idea of referring their service to God, of considering *him* as having appointed them their task, that they were doing *his* will, and were to look to *him* for their reward, was new; and affords a greater security to the master than any inferior principle, because it tends to produce a steady and cordial obedience in the place of that constrained service, which can never be trilled out of sight, and which is justly enough called eye-service. The exhortation to masters, to keep in view their own subjection and accountableness, was no less reasonable.

The Romans, besides their slaves, whom they also called *servi*, had another kind of servants, whom they called *nexi* and *addicti*, who were such as being in debt, were delivered up to their creditors by the praetor, to work out the debt, after which they were again at liberty.

The pope, out of his wonderful humility, calls himself in his bulls, *the servant of the servants of God, servus servorum Dei*. The first who used the appellation, as Diaconus tells, were pope Damasus, and Gregory the Great, which last is said to have used it to check, by his modesty, the arrogance of John, patriarch of Constantinople, who took the title of *acumenical*. Du-Cange adds, that the title servant has been assumed by some bishops, by some kings, and some monks.

SERVANT, in *Agriculture*, a person employed in the performing of some part of the business of a farm, of whatever kind it may be. On this subject, the following judicious hints have been thrown out by the author of the "Landed Property of England," for the direction of those servants who have the conducting of the management of farming

farming business. Nothing, he contends, contributes more to facility and satisfaction in this sort of business, than a forecast toward works to be done. A miscarriage is ever to be dreaded as a mischievous; and when it is brought on by a want of forethought, it brings with it a degree of discredit, and a train of unpleasant reflections, which form every enjoyment. This kind of servant should, he thinks, have a forecast towards crops for three or four years; toward team-labour for as many months; and should look forward with a view to hard labour for some weeks, according to the season of the year. And to bring it to a degree of certainty, it is necessary to make out a list of the fields, or parcels of land, of which the farm consists; with the crops which each has borne for some years back; together with the manurings which they have severally received, in order that the future treatment of each may be decided upon with sufficient accuracy. And to prepare every autumn, by the assistance of such list, an arrangement of the crops that are intended for the ensuing year; classing the fields, or pieces, according to the purposes for which they shall be intended: thus ascertaining the quantity of each crop, whether arable or grafs, as well as the quantity of ground intended for pasture; in order that the quantity of team-labour may be distinctly foreseen,—the required strength be estimated from time to time,—and the several crops be sown in due season; and in order that the stock of the ensuing summer may, in due time, be properly apportioned to the intended quantity of pasture ground; as well as that the works of summer and harvest may be constantly before the eye; and proper hands be engaged, in time, to perform them in season, and with the necessary dispatch and certainty. And he further advises a sort of memorandum list to be kept of business to be done,—immediately,—or in immediate succession; whether it relate to crops or to any other concerns of the farm; that nothing may escape the memory; and that the most requisite may be brought forward first; or another which is more suitable to the state of the weather, or other circumstances. In this, as well as other business, the great object to be aimed at is that of ensuring success; which is not only profitable to an employer, but satisfactory to the person employed. Whereas a miscarriage injures at once the property of the one, and the character, as well as peace of mind, of the other. Hence a farm manager ought to engage in a work, whether of improvement or ordinary practice, with caution; and to proceed in it with attention and firmness. A standing rule, respecting this main object of management, is not to attempt too much, and never to begin a work without a moral certainty of being able to finish it in due season.

Further; but besides the common work of a farm, as the culture and harrowing of crops, the rearing and fattening of live-stock, and the business of markets; there are various other objects of attention which ought to be constantly kept in the mind, or in the mind's way, of a manager; as on them the difference between good and bad, between correct and slovenly management, very much depends; such as keeping the homestead in repair, and free from impediments; attending to private roads and driftways; keeping up fences, every where, in thorough repair; attending particularly to young hedges, and to the rearing of hedge-row timber; the seeing that gates swing clear, and catch with certainty; equally to preserve them from injury, and to prevent loose stock from going astray; the attending to drains and water-courses; to see that superfluous waters have free passages to their proper outlets, and be readily discharged. And it is advised, that in summer strict attention be paid to drinking-

pools and other watering places of stock, as well as to the state of pasturing, and the flattening of pasturing stock. Likewise to weed, as well in grass grounds as in arable lands, to see that not a tumble-brew, nor any other weed matures its seed, either in the areas, or on the borders of fields, as great injury is done by their hiding their seeds.

Also in winter, much care is necessary to the cat-le-stock, not only to see that they are regularly supplied with proper fodder; but that sufficient shelter and comfortable resting-places are assigned them, so that they may be kept in a proper thriving state. At this season also the watering of grass-lands should be attended to as much as the nature of the situation will admit. And to the accumulation of manure an unremitting care should be bestowed the year round, as upon it much depends. And on the whole, to perform these and other objects with propriety, repeated examinations of every part and particular under his care; and committing to his memory whatever requires his more immediate attention; so that whether he is on the spot, or arranging his plan of operation, in the hour of leisure, it may be present to his mind, and take its proper course in the routine of work which is to be carried forward.

It may be noticed, that in the time of work the business of a managing servant lies in the field, in executing the plans he has formed, in passing from one set of work-people to another: not more to see that the different operations are rightly executed, with proper dispatch, than to order any required assistance, (to the teams most especially,) in order that every part of the machine may be kept in profitable motion. And that in the ordinary operations of husbandry, and on common occasions, a steady even pace be recommended; equally for the good of working animals, and the work which they are performing. Nevertheless, there are times when quick dispatch is necessary; and then it is his duty to encourage good speed; by his example, and by promises of reward, if the occasion require it. That at all times, and on every occasion, idleness is a crime which ought not to be suffered to pass with impunity. It is a direct fraud; and a manager should guard against it with the same care and assiduity as against pilfering. A day labourer who idles away an hour, robs his employer of an hour's wages; and thereby injures him as much as if he were to steal a faggot of equal value. This truth requires to be deeply imprinted on the minds of labourers. He has known the impression to have a good effect. But he properly remarks, that the right ordering of servants and work-people is a difficult branch of moral duty; and forms an important part of that of the managing servant. They require to be treated according to their respective merits; encouraging good ones by extra wages, or other rewards. Some men are worth double the wages of others, as day labourers. Yet custom makes no distinction between them in this respect! Hence the propriety of engaging the best workmen the country affords; and retaining them, by civil treatment, and suitable encouragements. The managing servant should keep his work-people at a proper distance, without destroying that free communication of opinion respecting the work in hand, which, on ordinary occasions, every intelligent workman should be allowed. And a standing rule of conduct, in the ordering of workmen, is never to find fault without occasion: nor to commend, without reason. Good fellows will not brook the former, nor will bad ones be mended by the latter. But it is right to habituate workmen in general to be told of their faults; first, in the mildest terms the occasion will admit of; reserving the warmth of temper for extraordinary occasions;

## SERVANT.

occasions; and then it is prudent to fling them with keen, rather than to load them with heavy, words: to endeavour to stir up their pride, rather than their malice or repentment. And much of the smoothness and uniform success of business depends on the manner of communicating orders to workmen. If orders are inaccurately or loosely given, it is unreasonable to expect that the execution of them should be faultless. It is difficult to explain business in words with sufficient accuracy to rustic workmen; and if a third person is suffered to intervene, errors are inevitable. The servant who has the management ought therefore to make a point of giving orders, in person, and if possible on the spot, to the men whom he means shall execute them. There he can explain himself to them intelligibly and fully; or assist them in marking out their work. There is always danger in merely verbal orders; and, in a message, certain mischief. It should be an invariable rule for him to set his men to a fresh work, in person; and if it is out of the common way of husbandry, to stay by them, or direct them with his own hands; and return to them, again and again, until he finds them completely in their work. In this view, this sort of servant, as well as for various other reasons, ought to be master of every implement, tool, and operation belonging to his profession; and if he find himself deficient in any particular, he should practise it day by day, until he make it familiar to him; or how is he to correct a bad workman; or to know when to be satisfied with a good one; who, knowing when he is right, will not bear the reproaches of ignorance? He has no other way of securing the esteem and attachment of good workmen, and of finishing in a workman-like manner every thing he undertakes, than by making himself master of his business; without which little satisfaction will arise from it to himself, or profit to his employer. And in the general principles of conduct, in his dealings and intercourse with other men, punctuality is one of the most essential. Method is the best assistant of punctuality; and clear accounts are one of the best results of method. These should always be kept with exactness, and be sent, when required, to the proprietor, in weekly, monthly, and annual periods, so as to shew the daily state of the work; the monthly state of receipts and payments; and, lastly, the whole state of accounts and balances.

Besides, it is extremely necessary for the farmer to be careful in providing his servants, not only to see that they are proper for the work, but that there be not more than are necessary for executing it, as the expence of them is now become extremely great. It has long since been recorded by the above writer, in his "Minutes of Agriculture," that on the maturest calculation he found the yearly expence of a man servant in the house to be 35*l.*, and that of a boy 23*l.*, supposing the man's yearly wages to be 10*l.* and the boy's 3*l.* Now the expence of a day-labouring man for a whole year (if he works every day) is but 27*l.* 10*s.*, which is 7*l.* 10*s.* difference against keeping a man in the house by the year, and hiring one by the day. But that of a boy is still more in proportion, *viz.* the expence of a day-labouring boy for a whole year, if he works every day, is but 13*l.*, which makes a difference of 10*l.*, or more than three-fourths of a boy's day-wages. In the above account, no deduction in the daily pay is made for rainy days. The impropriety, therefore, of keeping plough-boys in the house is very visible: and though it may be convenient to have the carters about the house, the conveniency is not worth 7*l.* 10*s.* a-year. He therefore recommends putting a woman into a cottage, within about two hundred paces of the farm-yard, to take in lodgers; and to keep in the house no more

farming servants than a butler and a yardman. Indeed he says it is absolutely necessary to have somebody about a farm-yard in cases of emergency; but the above two are sufficient, as the carters in the adjoining cottage will be nearly as handy as if they were in the house. This measure, it is observed, like many others, is merely local, but the hint is universal.

But perhaps the farmer, who keeps no accounts, imagines he saves money by boarding his servants in the house; however, if he keeps them in the luxurious manner which farming-servants in general expect to be kept, he will be mistaken. A farmer, indeed, who sits at the head of his kitchen-table, may no doubt feed his men considerably cheaper, than a person who eats in a separate apartment. It is a just observation, that one fed by his master costs the community as much as two who provide for themselves; for discharge a grumbler, one who pretends to be dissatisfied, though in fact only satiated, and he will return to his bread and cheese with perhaps equal health and equal happiness. He sits down to his master's table with a resolution to eat voraciously of the best, to do himself justice; but at his own table eats sparingly of the meanest, to save his money. His motive in both cases is the same; self-interest. The plan here inculcated is at this time still more necessary than it was at a former period.

And it is added, that in some counties, particularly in Surrey, it is an established custom for every man, in harvest, to work by the acre, or by the month, not by the day. If a labourer be constantly employed through the year, he expects during harvest to be constantly employed in mowing, reaping, &c. by the acre, or to have his harvest-month; that is, to have an advance of wages certain, wet or dry, during one month; which month commences when it best suits his employer. This is very convenient; they are always at command in cases of emergency; and nothing but a continuance of rains while the barns are empty can make them burdensome. He strongly recommends the employing of active young men; for one invalid or sluggish fellow will spoil the whole set; and this holds generally. Mix two or three old women, or two or three boys, with a company of men, and the effect will be very soon visible; for the men will soon conform to the ways of either the old women, or the playfulness of the boys. It is not prudent to employ many women with the men; and nothing but necessity can excuse it. Two women after the first or second day, will do as much work as half a dozen, alone. If it be necessary or convenient to employ a number of both men and women, it is but common good management to keep them separate; with this exception, which may be laid down as a maxim, *viz.* one man among women, and one woman among men. A crusty conceited old fellow will check the gossiping of the women, and it has been remarked that raking after a young wench has animated more than a gallon of ale. Two are dangerous; they breed contention, and rather retard than accelerate. The most valuable servant in harvest is a good carter. It is necessary to common management that he should be able, willing, and careful. Every pitch of hay and corn, generally speaking, passes twice through his hands; he loads and unloads, which are the two most laborious tasks of harvest; he drives the team backwards and forwards; if he loiters by the way, the field-men or stack-men must stand idle; if he spill or overturn his load, or if he break his waggon, or set his horses, the arrangement of the day is broken; and, perhaps, the damage done by the loss of time rendered irreparable by the next day's rain. A good carter will not suffer

## SERVANT.

suffer his waggon to be overloaded. The field-men, too, that is, the pitcher and assistant-loader, should be young and active, and well matched with the carter.

But since the above was written, the prices of servants have considerably increased in every district of the kingdom, and the expences of keeping them been very greatly augmented. This has led to fewer being kept, and especially in the house. It is stated, that in Hertfordshire the annual wages of a carter or ploughman was formerly from six to nine guineas; boys from two to four guineas; and maid-servants about five guineas; but they have since risen to nearly double these sums. And formerly in Norfolk farm-work was particularly distinguished by the cheapness as well as expedition with which it was performed; which, it is said, arose not merely from the cheapness of labour, but the greater exertions of servants and labourers than in most other districts; but this is considerably diminished at present. In some parts of that district the custom of allowing board-wages to farm-servants, instead of the old plan of feeding them in the house, is coming into use; and 8s. a-week are given. This is a bad, immoral regulation, which should be discontinued. In Yorkshire the wages of servants have also been greatly increased. In the West Riding the wages of a house servant (of which kind most of the ploughmen are) may be estimated from 25*l.* to 30*l.* yearly, including maintenance. There is a practice which prevails over a considerable part of this district, of giving them drink both forenoon and afternoon, be the work what it will; which is a ridiculous custom, and ought to be abolished without loss of time. What can be more absurd than to see a ploughman stopping his horses half an hour, in a cold winter day, to drink ale? But the practice is so deep rooted, that it will not be easily removed without a compensation. It is suggested that the proper remedy is to let the value of the ale be paid to the servant in money, which probably would be as much for his interest, and certainly more advantageous to the farmer. In those places where long yokings are taken, say seven or eight hours, it may be necessary to feed both men and horses on the ground; but this practice cannot be recommended unless in urgent cases, it being very injurious to their health. In the best regulated agricultural counties, five hours labour in the morning and four hours in the afternoon, when the season allows, and five hours, or five hours and a half, in short days, is considered to be as much as horses are capable of sustaining, and yokings of this duration require no refreshment on the ground. And it is added, that the hours of labour for men are generally in summer from six to six, with the usual time for rest and refreshment, which gives betwixt nine and ten hours labour each day, and in winter from light to dark. Much of the farm-labour, such as ditching, hedging, threshing, &c. is done by the piece, but the prices vary greatly in different places. And it may be added that when the farmer is a proper judge of his business, piece-work is not only most to his advantage, but the only way by which an active diligent servant can be properly rewarded for his labour.

In Berkshire, and many other counties, great care is taken to keep no more servants in the house, by the farmers, than are just sufficient for performing the ordinary business to be done. The pay of a carter is there from nine to twelve guineas the year; an under carter from four to seven guineas for the same length of time; a shepherd from eight to ten guineas, and the run of a few sheep; a boy from two to three guineas; and a dairy-maid from five to ten guineas, in proportion as she may be qualified.

In the manufacturing districts of Cheshire and Lancashire, the wages of house-farming servants run in this way.

In the first,

	£	£	
Man to follow the team	-	-	from 10 to 12 <i>per annum.</i>
Lad of from 15 to 20, for the same purpose	-	-	8 — 10
Cow boy, or man, as the stock may be	-	-	8 — 12
Home-work servant, for hedging, mowing, threshing, &c.	-	-	10 — 12
Head dairy woman, in proportion to the size of farm	-	-	10 — 14
Women servants of other kinds	-	-	4 — 6
Girls	-	-	2 — 4

In the latter,

Men servants	-	-	from 10 to 25
Lads	-	-	6 — 10
Women	-	-	5 — 8
Girls	-	-	2 — 4

They have lately been considerably on the increase in both of these districts.

In the county of Essex, and many other districts which are principally agricultural, the work of the farms is in a great measure executed by hired daily or weekly labourers, very few yearly servants being kept by the farmers. This is supposed, in many instances, to be not only the cheapest, but the most convenient method of having such sorts of work performed; and the farmers are, at the same time, the most free from trouble in their houses and families. In the very southern agricultural districts of Devonshire and Cornwall, the wages of the farm servants, kept in the house, with washing and lodging, are, in the former, for a carter or head man ten pounds the year, the inferior sorts of farm business being often accomplished by parish apprentices; and in the latter, from eight to twelve guineas, with their board, for men, and from three to four pounds, with the same, for maid servants during the year. These rates, however, vary a little, according to the qualifications of the servants, and the nature of the situations and farms.

In the county of Herefordshire, where the hours of labour are from light to dark in the winter, and from six in the morning to the same hour in the afternoon, in summer, the following are the average prices of wages now given to servants kept in the house by the farmers.

Waggoner,	-	-	10 to 12 guineas <i>per annum.</i>
Bailiff or cattleman,	-	-	8 — 10 ditto.
Dairy-maid,	-	-	6 — 7 ditto.
Under-maid,	-	-	2 — 3 ditto.

Likewise in East Lothian, in Scotland, the wages are mostly from ten to fourteen pounds *per annum*; but this class of servants is but small. The female servants have from four pounds to four pounds ten shillings, or five pounds. And in Clydesdale, the greater part of the agricultural labour is performed by servants hired by the half year, and living in the farm-houses. In many parts of the county the women servants work along with the men, at almost all kinds of out-work. But as more hands than ordinary are needed for cutting down the corn in harvest, many husbandmen, to secure a fixed number for that purpose, when they can be got, contract with villagers to assist during the time of reaping. All these labourers have no fixed hours, but continue their labour while light and weather admit, and circumstances require. The poor girls, when light is gone and the men sit down by the fire, resume their household labours.

The

## SERVANT.

The labourers, both men and women, are sometimes hired by the day, particularly in the time of planting, sowing, and hoeing turnips and potatoes, hay-making, and harvest, when a fixed number is not provided. These work only ten hours in the day, beginning at six in the morning and stopping at six at night, and taking an hour to rest at breakfast, and another at dinner. Hired labourers, in winter, take breakfast before they go out in the morning, make a short pause to eat a little at mid-day, and quit when light fails in the evening. The following are the prices of wages.

	Former.	Present.
Wages of men servants, besides bed, board, and washing, <i>per ann.</i>	from 13 <i>l.</i> to 16 <i>l.</i>	from 20 <i>l.</i> to 25 <i>l.</i>
Wages of a maid servant, besides bed, board, and washing, <i>per ann.</i>	— 5 <i>l.</i> to 7 <i>l.</i>	or 8 <i>l.</i> to 9 <i>l.</i> 10 <i>s.</i>

But in Perthshire, a man servant, who is master of all the operations in farming, only receives, in the corn country, between eight and twelve pounds, for twelve months. In the grazing districts, more remote from the seat of manufactures, their wages, and the price of all kinds of labour, are about one-fourth lower. But in many cases the servants are maintained in the farmer's family; but the practice of giving them six and a half bolls of meal, together with a house, garden, and a cow's grafs, free of rent, and some fuel, is daily becoming more general. These farmers, who keep any married servants, have them all on this establishment of livery meal. The maid servants live all in their master's family, and are engaged for betwixt three and four pounds, and in some cases five pounds of yearly wages, according to their expertness, and the nature of their work. But common labourers earn between one shilling and one shilling and three-pence a day; and if able-bodied and handy, they demand one shilling and sixpence, without victuals. The various denominations of artificers charge according to the nicety of their art. The hours of labour from the vernal to the autumnal equinox, are from six to six, allowing an hour for breakfast and another for dinner; and during the other half year, from the dawn of day till the light fails at night, with an allowance of one hour for breakfast. Household servants are not so exact with respect to hours; in the long days, they continue to work after six at night; and in short days they get out of bed before day light, where there is much grain to thrash. But in many of the large farms, thrashing machines have been erected; and they are such a great saving, by the abridgment of labour, that more of them are set up every year, in different parts of the county.

And in Argyleshire, within these 30 years, the price of labour is somewhat more than doubled. It still varies in different parts of the county, but may be estimated in general at the following rates. A man servant's wages, *per annum*, with victuals, from 6*l.* to 8*l.* A maid servant's, from 50*s.* to 4*l.* And that since 1795 the wages and the price of labour have been advanced more than one fourth, or from 25 to 30 *per cent.*, and are still rising.

Further, in regard to the regulating the rate of wages, it has been suggested in the Agricultural Survey of the West Riding of Yorkshire, that the only mode of making them proportional to the rise or fall on the value of money and provisions, is to pay the labourer in kind, that is, with a certain quantity of corn, as parties shall agree, which insures him, at all hazards, a comfortable subsistence, and prevents him from a daily or weekly visitation of the markets. When

the labourer is paid in money, it exposes the thoughtless and inattentive to many temptations; whereas, when paid in kind, he cannot raise money to gratify the whim of the moment. In those counties where this mode of payment has been long established, we believe the ploughmen and labourers are, on the whole, better fed, live more comfortably, and rear healthier children than in those parts where, from being paid in money, the currency of the article facilitates the expenditure, and prevents him from laying by a stock of provisions for his support, when laid off work by casualties or distress. In the part of the kingdom where the writer resides, nearly all farm-servants are paid in this manner. They have a certain quantity of grain, maintenance for a cow summer and winter, a piece of ground for planting potatoes and raising flax, and whatever fuel they require, given gratis. These, with the privilege of keeping a hog and a few hens, enables them to live, and bring up their families in a comfortable manner; and, while their income is considerably less than people of their station in other parts, they are, on the whole, better fed, better dressed, and enabled to give a better education to their children. Placed under these circumstances, they are a respectable set of men; and, for frugality, faithfulness, and industry, they will bear a comparison with their brethren in any quarter. The introduction of a similar mode of paying farm-servants into the West Riding, is therefore recommended, which, although it might at first be attended with some difficulties, would contribute to the public good, and to the advantage of the labouring peasantry in many respects. And it is remarked in the Herefordshire Agricultural Survey, that if a certain proportion between the price of labour and the average price of wheat could be fixed by law, so as to render the applications for parochial aid necessary only in cases of very large families, of unusual illness, of scanty seasons, or any other real emergency; the measure, it is presumed, would stimulate industry and fidelity, would check dishonesty, and endear to a numerous class their native soil.

The advance in the rate of farm-servants' wages who live in the houses of the farmers, has, within the last twenty-five years, been probably not less than from a third to a fourth of the whole, according to the nature and situation of the district, over the whole country; but how far the agricultural and manufacturing state of the nation may thereby be affected, is difficult to determine.

It is a matter of very great consequence to farmers, to have good, tractable, intelligent, able, and honest servants, as no sort of good farm-work, or improvements, can be properly carried on without them.

**SERVANTS' Rooms**, in *Rural Economy*, the lodging places for farm-servants, which should always, if possible, be distinct from the house upon farms of considerable size. And in cases of very extensive farms, and of course where many servants are required, especially if they be unmarried, proper and convenient accommodations for sleeping, and where they find their own provisions, for preparing and dressing them in, are not only requisite, but highly advantageous, both to the farmer and the men, as saving much time, which would otherwise be lost in going to their meals, and keeping them together sober, steady, and ready for their different employments. And in this way the servants are much more comfortable, and live considerably cheaper than where it is the custom to go to public houses, or other such places for their meals, which is too much the case in many of the more southern districts of the kingdom, by which their manners often become depraved, and their constitutions enfeebled by the great use of spirits, and other intoxicating liquors, which they are almost necessitated to take under

under such circumstances. But these inconveniences are perhaps the most effectually guarded against by such servants being provided for, where it can be done, from the tables of the farmers. But where this last method is followed, the eating rooms should be so situated, that they may be overlooked with facility. Their lodging rooms, in all cases, are the most proper and the safest, when made in a building quite detached and distinct from the other houses and offices; as persons of this description are often extremely negligent of their fires, candles, &c., as well as irregular in other parts of their conduct. It has been advised, that whatever situation may be fixed upon for these conveniences, the ground-floors should always be of stone or brick, and the upper ones made with plaster, as is done in some of the midland counties, or brick, which is more easily laid. See *PLASTER Floors*.

Most kinds of farm labour may, however, probably at present be performed more cheaply by other sorts of workmen, than servants provided for in any of these ways.

**SERVE**, in the *Sea Language*. *To serve* a rope, is to lay spun-yarn, rope-yarn, fennit, a leather, a piece of canvas, or the like upon it, which is rolled fast round about the rope, to keep it from fretting or galling in any place.

**SERVERETTE**, in *Geography*, a town of France, in the department of the Lozere; 12 miles N.N.W. of Mende.

**SERVETISTS**, in *Ecclesiastical History*, a sect said to be the disciples or followers of Michael Servetus, the ring-leader of the Anti-Trinitarians of these last ages. See his article.

It is impossible (says the translator of Mosheim's *Ecclesiastical History*.) to justify the conduct of Calvin in the case of Servetus, whose death will be an indelible reproach upon the character of that great and eminent reformer. The only thing that can be alleged, not to efface, but to diminish his crime is, that it was no easy matter for him to divest himself at once of that persecuting spirit, which had been so long nourished or strengthened by the popish religion in which he was educated.

Servetus, in reality, had not any disciples, as being burnt, together with his books, before his dogmas had time to take root. But the name Servetists has been given to some of the modern Anti-Trinitarians, because they follow the footsteps he had marked out.

However, those who were denominated Servetists, or Servetians, by the theological writers of the sixteenth century, not only differed from Servetus in many points of doctrine, but also varied widely from him in his doctrine of the Trinity, which was the peculiar and distinguishing point of his theological system.

Sixtus Senensis calls the Anabaptists Servetists, and seems to use the two terms indifferently. The truth is, in many things, the ancient Anabaptists of Switzerland, &c. coincide in opinion with Servetus.

As the books that he wrote against the Trinity are very rare, his real sentiments are but little known: M. Simon, who had a copy of the first edition, delivers them at large in his critical history.

Though Servetus uses many of the same arguments against the Trinity as the Arians, yet he professes himself very far from their sentiments. He also opposes the Socinians in some things; and declares his dissent from the opinions of Paulus Samofatenus; though Sandius mistakenly charges him with having the same sentiments.

In effect, he does not seem to have had any fixed regular

system of religion, at least not in the first edition of his book against the Trinity, published in 1531, under the title "De Trinitatis Erroribus Libri septem, per Michaelem Servetum, alias Reves, ab Arragonia Hispanum."

The year following he published his dialogues on the mystery of the Trinity. In the preface to which last work he declares himself dissatisfied with it. It was on this account he undertook another on the same subject, of much greater extent, which did not appear till the year 1553, a little before his death, under the title of "Christianismi Restitutio."

Those of Geneva, having seized the copies of this edition, had it burnt; nor were there above two or three that escaped; one of which was kept at Basil, where the book was printed, but is now in the college library at Dublin.

It was put to the press secretly in England, but being discovered, the impression was seized and destroyed.

Servetus, according to Mosheim's account, conceived that the genuine doctrine of Christ had been entirely lost, even before the council of Nice; and he was moreover of opinion, that it had never been delivered with a sufficient degree of precision in any period of the church. To these extravagant assertions he added another still more so, even that he himself had received a commission from above to reveal anew this divine doctrine, and to explain it to mankind. His notions with respect to the Supreme Being, and a Trinity of persons in the godhead, were very obscure and chimerical, and amounted in general to the following propositions: that the Deity, before the creation of the world, had produced within himself two personal representations or manners of existence, which were to be the medium of intercourse between him and mortals, and by whom, consequently, he was to reveal his will, and to display his mercy and beneficence to the children of men: that these two representatives were the Word and the Holy Ghost: that the former was united to the man Christ, who was born of the Virgin Mary, by an omnipotent act of the Divine Will; and that, on this account, Christ might be properly called *God*: that the Holy Spirit directed the course, and animated the whole system of nature, and more especially produced in the minds of men wise counsels, virtuous propensities, and divine feelings; and, finally, that these two representations were to cease after the destruction of this terrestrial globe, and to be absorbed into the substance of the Deity, from whence they had been formed.

Servetus, however, did not always explain his system in the same manner, nor avoid inconsistencies, contradictions, and ambiguities; so that it is extremely difficult to learn his true sentiments. His system of morality agreed in many circumstances with that of the Anabaptists, whom he also imitated in censuring with the utmost severity the custom of infant-baptism. *Ecclesiastical History*. vol. iv. 1768.

**SERVETUS, MICHAEL**, in *Biography*, was born at Villanueva, in Arragon, in 1509. His father was a notary-public, and he himself was sent to the academy of Toulouse, where he studied the law during the space of three years. About this period his attention was turned to the study of the sacred scriptures, to which he was probably excited by the reformers of that day. He soon discovered many errors and abuses in the church of Rome, in the tenets of which he had been brought up, and laid then the foundation of his opinions concerning the doctrine of the Trinity. It is known, that at this period, many learned men in Italy and other parts, among whom were some dignitaries

of the church, condemned in private the reigning superstitions, to which, however, they readily conformed in public. Whether Servetus was instructed by any of these, or whether his own opinions were the result of investigation, cannot be ascertained: it is certain, that he did not think it prudent to divulge them in France, and therefore retired to Germany, where a much greater liberty of conscience was allowed and asserted, and where several princes secretly favoured the bold attacks on the popedom. He went through Lyons and Geneva to Switzerland, and fixed his residence at Basil in the year 1530. Here he was on a footing of friendly intimacy with *Æcolampadius*, with whom he often conversed about various religious topics, but to whose peculiar opinions he would not yield, in the smallest degree, any notions which he had previously adopted. The unbending disposition with regard to matters of small moment, alienated many persons from Servetus who had formed a high opinion of his talents and integrity. While he was at Basil, he put into the hands of a bookseller a manuscript, "*De Trinitatis Erroribus*," which was printed in the year 1531. Servetus now went to Straßburg, in which city he became acquainted with two reformers, *viz.* *Capito* and *Bucerus*. Here he searched for opportunities to communicate his religious tenets to his new acquaintances, and here he learned that his work had excited a considerable sensation among people of all classes. He was aware that he had, in many respects, treated the subject too imperfectly; and had made use of expressions that were liable to give offence; he accordingly, in the following year, endeavoured to soften the unfavourable impression, and to avert a storm that seemed threatening to fall upon him, by publishing a work entitled "*Dialogorum de Trinitate Libri duo*," in which he explained and defended his opinions. The consequences of this second piece was, that many were exasperated against the author, while a few adopted his doctrines and spread them abroad. *Æcolampadius* requested his friend *Bucer* to inform *Luther*, that Servetus's book had been published without their knowledge, in order that it might not be supposed they had given any countenance to the propagation of the offensive tenets. And *Melanchthon*, in speaking at this time of Servetus, says, "He wants neither acuteness nor cunning in disputing, but I cannot allow him energy. He has, moreover, as it appears to me, confused imaginations, neither is he able sufficiently to explain his thoughts with precision. He unquestionably speaks like a madman about justification; about the Trinity, *πρὸς τὴν τριάνοον*, you know that I have been always apprehensive that similar things sooner or later would break out. Good God! what tragedies will this question excite among posterity."

The circumstances of Servetus being low, he engaged for some time with the *Frellons*, eminent booksellers at Lyons, as corrector of the press. From Lyons he went to Paris, where he studied physic under the celebrated *Sylvius*, *Fernelius*, and other professors; and, as we shall have occasion to remark hereafter, he carried into that science the same penetrating spirit and love of improvement which distinguished him in theology. He graduated at Paris, and being invested with this honour, he delivered public lectures in geography and some branches of mathematics, while he followed the profession of a physician. At Paris he quarrelled with the faculty, and wrote an "Apology," which was suppressed by the parliament. After quitting that capital he practised physic at *Charlieu*, near Lyons, whence, at the invitation of the archbishop of Vienne, he removed to that city, and had apartments near

the palace. He had, previously to this, *viz.* in 1542, superintended the printing of a Latin Bible at Lyons, to which he added marginal notes, under the name of *Villanovanus*.

During this time, Servetus was in constant correspondence with Calvin, with whom he discussed various points of controversy, and to whom he opened himself freely and without reserve concerning his particular notions, and consulted him respecting his writings. Calvin afterwards made a safe use of this confidence, by actually producing his letters and manuscripts as matter of accusation against him on his trial. It must not, however, be concealed, that Calvin does not appear to have encouraged Servetus to this exposition of his sentiments, for he frequently sent him in reply angry and severe letters. In 1553, Servetus published his matured theological system under the title of "*Christianismi Restitutio*." Conscious of the danger to the author of such a work in a Catholic country he concealed his name, but Calvin took care that the magistrates of Vienne should be informed of it. He was in consequence thrown into prison, and his death would have added an example to the numberless cruelties of Roman Catholic persecutions, had he not made his escape. His effigy and his books were condemned to the flames. Servetus, purposing to go to Naples to practise in his profession, imprudently went through Geneva. Calvin, who was acquainted with the plans of the traveller, and who was on the watch to entrap him, gave information to the magistrates the moment he arrived within the gates of the city. He was accordingly seized, thrown into prison, and a charge of blasphemy and heresy was preferred against him by Calvin's own servant. In order to ensure conviction and condemnation, no less than thirty-eight articles of accusation were brought against him, for which not only his last work, but all his other writings were ransacked. As a proof of the malice and unfairness with which he was treated, it is mentioned that one of the charges was extracted from his preface to an edition of *Ptolemy's Geography*, published twenty years before, in which he had asserted, that *Judea* had been falsely extolled for its beauty and fertility, since modern travellers had found it to be sterile and unsightly. That no doubt might be left whence the prosecution came, one of the main articles against the prisoner was, that in the person of *Mr. Calvin*, minister of the word of God in the church of Geneva, he had defamed the doctrine preached in it, uttering all imaginable injurious and blasphemous words against it.

Servetus, in the first examination, repelled with firmness every accusation, though he avowed that he published in Germany his book "*De Trinitatis Erroribus*;" in France his "*Restitutio Christianismi*," together with *Ptolemaeus*, and the edition of *Pagnini's bible*. At the second examination, he acknowledged, when urged to confess the truth, some of the articles brought against him in regard to his publications, denied others, and hesitated to explain himself more plainly upon others. But when he was again questioned, "why he had slandered Calvin, and lacerated the Christian doctrine?" he protested that Calvin had been the aggressor, and that if he had recriminated it was done in self-defence; which plea was deemed by his judges as an aggravation of his offence.

The magistrates of Geneva were, however, sensible that many eyes were upon them in this extraordinary proceeding, with respect to one who was no subject of their's, nor a resident in their city, nor could he be accused of having committed any offence in their territory, and within their jurisdiction. He was, in truth, kidnapped in his passage.

Moreover,

Moreover, it could not but appear strange, that men should be associates in persecution, with those very people who would infallibly burn them as heretics, should they fall into their hands. They therefore thought it advisable to consult the magistrates of the Protestant cantons of Switzerland, to whom they sent Servetus's book, with Calvin's reply. The Helvetic divines, to whom the matter was referred, unanimously declared for his punishment: they said that Servetus's errors ought to be detested, and that great care ought to be taken that the infection spread no farther, and that the man ought to be restrained; but they, none of them, said a word respecting capital punishment, nor do they allude to the kind of coercion that should be chosen. Their meaning was, however, readily inferred from their own practice; for the capital punishments of heretics had not been abolished in Switzerland; they had been frequently practised at Zurich against the Baptists.

Servetus was for a time kept ignorant of all the proceedings against him; at length he discovered the intentions of his enemies, and drew up, and caused to be presented, two petitions to his judges: in the first he endeavoured to exculpate himself; in the second he complained that a fair trial had not been allowed him. As he refused to retract his opinions, he was, notwithstanding his pleas, condemned to the flames as an obstinate heretic, which cruel sentence was carried into execution on the 27th of October 1553, when he was in the forty-fourth year of his age. His sufferings were particularly severe, and the fire was so managed, that the unfortunate man lingered in excruciating pain more than two hours.

That this bloody persecution was disapproved by many at the time, is rendered very probable by the apology for the Geneva magistrates, published by Calvin, in which he undertook to prove that it was lawful to punish heretics with death. The mild and otherwise moderate and benevolent Melancthon sanctioned the deed by a congratulatory letter addressed to the magistrates of Geneva. The conduct of Calvin in this business, as instigated not only by bigotry, but personal hatred, has impressed an indelible stain on his memory; and the only possible excuse now offered for it arises from the provocation given by Servetus, "whose excessive arrogance," according to Mosheim, "was accompanied with a malignant and contemptuous spirit, and an invincible obstinacy of temper."

The theological system of Servetus is described as singular in the highest degree. The greatest part of it was a necessary consequence of his peculiar notions concerning the universe, the nature of God, and the nature of things, which were equally strange and chimerical. See the article **SERVETISTS**.

Servetus is numbered among those anatomists who made the nearest approach to the doctrine of the circulation of the blood. The passage cited to this effect is contained in his latest and fatal work, "De Restitutione Christianismi." It clearly states the circulation of the blood through the lungs. He pursued, in his medical studies, anatomical researches with the greatest ardour.

Servetus was a man of great erudition and unfeigned piety; his mind was stored with a variety of knowledge, and he stood very high, in the estimation of his contemporaries, for his talents and for his discoveries in the profession of medicine. Whatever might have been his errors as a theologian, it is certain he never preached them to the vulgar, but communicated them freely to Calvin, Œcolampadius, Capito, Bucerus, and other reformers, with an eagerness to discover truth which has never been surpassed.

The atrocious murder committed on him will not ad-

mit of a single excuse. His imprisonment was scandalous and unjust. The senate of Geneva had no right to lay violent hands upon a traveller, who had no intention of remaining in their city, and who probably never uttered within the precincts of their dominions one syllable of his obnoxious opinions. Here Geneva stands condemned by all civilians.

The affability of the manners of Servetus, and his vast learning, had procured him numerous friends in France, in Germany, and in Italy: and his name will be handed down to the latest posterity with commiseration and respect. See a life of Servetus, in a series of letters to Jedidiah Morfe, D. D., by Fr. Adrian Vanderkemp: inserted in vol. v. of the Monthly Repository.

**SERUG**, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 12 miles S. of Ourfa.

**SERUGNANO**, a town of Italy, in the Veronese; 8 miles E.N.E. of Verona.

**SERVIA**, a province of Turkey in Europe, part of the ancient Pannonia, or of Turkish Illyria, deriving its name from its inhabitants, is bounded on the N. by Bosnia and Sclavonia, on the E. by Walachia and Bulgaria, on the S. by Macedonia and Albania, and on the W. by Bosnia and Dalmatia. It was formerly divided into Proper Servia, or Serbia, and Rascia, and the inhabitants were distinguished into Servians, and Rascians or Reitzes; and the former, which constitutes the upper part, towards the Danube, belongs to the bannat of Masovia. The capital of Servia is Belgrade, (which see). The Turks call it Laş Vilayeti, or Lazarus-land, because in the year 1365, when they subdued it, Lazarus was prince of Serbia. See **SERVIANS**.

**SERVIAN**, a town of France, in the department of the Hérault, and chief place of a canton, in the district of Beziers; 6 miles N.E. of Beziers. The place contains 2200, and the canton 7319 inhabitants, on a territory of 117½ kilometres, in 9 communes.

**SERVIANS**, or **SERBES**, a branch of the Illyrian Slavi, who gave name to the province called Servia or Serbia. In the Russian empire the Servians and Reitzes are colonists, to whom, in the year 1754, a considerable district was allotted on the Dnieper near and upon the possessions of the Zaporagian Cossacks. This country, which got the name of New Servia, was for the most part an uninhabited desert, extending to what were then the Polish borders, by which it was surrounded on three sides. The Servians, who voluntarily settled here in great numbers, were formed into a military association, to be a check upon the dissensions and excesses of the Zaporagians. In the year 1764, the whole of this tract of country was erected into the government of New Russia, and at present forms a considerable part of the province of Ekaterinofslaf.

**SERVICE**, or **SERVAGE**, *Servitium*, in *Law*, a duty which the tenant, by reason of his fee, owes to the lord.

This, in pure, proper, and original feuds, was only twofold: to follow, or to do suit to, the lord in his courts in time of peace; and in his armies, or warlike retinue, when necessity called him to the field.

Ancient law-books make several divisions of service, viz. into *personal*, *real*, and *mixt*; *military* and *base*, *intrinsic* and *extrinsic*, &c. But, since the statute 12 Car. II., by which all tenures are turned into free and common socage, much of that learning is set aside. Yet it may not be amiss to mention how the several kinds of service are described in our ancient law-books.

**SERVICE**, *Personal*, is that to be performed by the person. Such is that due from a slave to his master.

Personal service is a disgraceful sort of tenure, under which lands were formerly held, and in which the tenant did various sorts of work for the lord, and provided him with a variety of different articles. It is a custom which has long been abolished in this part of the kingdom, as being highly injudicious and improper; but which, Mr. Donaldson remarks, is not wholly discarded in Scotland. "In the north of Scotland," says he, "the rents are to a certain extent paid in personal services; the tenants being bound to plow and harrow a certain proportion of the proprietor's farm; to reap, carry home, thrash, dress, and mill a certain quantity of his crop at their own charges; and that they are also bound to pay poultry, eggs, cheese, sheep, swine, fish, linen, yarn, &c." It might, continues he, have been unavoidably necessary, from the want of a circulating medium in the early periods of the history of this country, to oblige the tenants to pay their rents in personal services, and in the various articles of produce which their farms afforded; but it must be considered a singular circumstance in the history of Great Britain, that in the end of the eighteenth century, and at a period when the introduction of improvements in agriculture is the chief topic of conversation, there should exist proprietors, who are so lost to every sentiment regarding what is due to the community of which they are members, to the people whom Providence has placed under their protection, and to the improvement of their native country, as to persist in demanding from their tenants a species of rent, which no farmer, who is entitled to the name, would submit to pay, nor any proprietor, who regarded the good of his country, or his own interest, think of requiring. These disgraceful services should of course be done away with in every situation, as being incompatible with all sorts of improvements in husbandry, or the introduction of spirited agriculture into any part.

This sort of service is not only hostile to all kinds of farming improvements, but highly distressing and ruinous to tenants at particular seasons, as during the seed-time, the harvest, and the time of getting in the hay, by being often under the necessity of neglecting their own operations and businesses, in order to perform the various works of their lords, or superiors. The sooner these services are wholly abolished in every part of the kingdom, the better it will be for the interests of agriculture.

SERVICE, *Real*, is either *urbane* or *rustic*; which two kinds differ, not in the place, but the thing. The first is that due from a building or house, in whatever place situate, whether in city or in country, as keeping a drain, a vista, or the like.

SERVICES, *Rustic*, are those due for grounds, where there is no building; such is the right of passage through ways, &c.

SERVICE, *Mixt*, is that due from the person, by reason of the thing, as an usufruct, &c.

Our ancient law-books tell us of lands held of the king, by the tenant's letting a fart before the king on New Year's Day; others, by furnishing the king with whores, whenever he travelled that way; others, by bringing the king a mess of pottage at his coronation-feast, &c.

There are also *natural* services. For instance, if a man cannot gather the produce of his lands, without passing through his neighbour's grounds, the neighbour is obliged to allow a passage, as a natural service.

SERVICE, *Forensic* or *Extrinsic*, *Servitium forensicum*, &c. was a service which did not belong to the chief lord, but to the king.

It was called *forensic* and *extrinsic*, because done *foris*,

out of doors; and *extra servitium*. We meet with several grants, in the Monasticon, of all liberties, with the appurtenances, *salvo forensi servitio*.

SERVICE, *Intrinsic*, *Servitium intrinsicum*, that due to the chief lord alone, from his vassals within his manor.

SERVICE, *Frank*, *Servitium liberum*, a service done by the feudatory tenants, who were called *liberi homines*, and distinct from vassals: as was likewise their service; for they were not bound to any base services, as to plow the lord's lands, &c. but only to find a man and horse to attend the lord into the army or court.

SERVICE, *Base*. See VILLENAGE.

SERVICE, *Bord*. See BORDAGE.

SERVICE, *Foreign*, *Honorary*, *Knights*, *Rent*. See the adjectives.

SERVICE, *Heriot*. See HERIOT.

SERVICE, *Ovelty of*. See OVELTY.

SERVICE, *Suit of*. See SUIT.

SERVICE, *Choral*, in *Church History*, denotes that part of religious worship which consists in chanting and singing. The advocates for the high antiquity of singing, as a part of church music, urge the authority of St. Paul in its favour: Ephes. chap. v. ver. 9. and Coloss. chap. iii. ver. 16. On the authority of which passages it is asserted, that songs and hymns were, from the establishment of the church, sung in the assemblies of the faithful; and it appears, from undoubted testimony, that singing, which was practised as a sacred rite among the Egyptians and Hebrews, at a very early period, and which likewise constituted a considerable part of the religious ceremonies of the Greeks and Romans, made a part of the religious worship of Christians, not only before churches were built, and their religion established by law, but from the first profession of Christianity. However, the era from whence others have dated the introduction of music into the service of the church, is that period, during which Leontius governed the church of Antioch, *i. e.* between the year of Christ 347 and 356. See ANTI-PHONY.

From Antioch the practice soon spread through the other churches of the East; and in a few ages after its first introduction into the divine service, it not only received the sanction of public authority, but those were forbid to join in it who were ignorant of music. A canon to this purpose was made by the council of Laodicea, which was held about the year 372; and Zonaras informs us, that these canonical singers were reckoned a part of the clergy. Singing was introduced into the western churches by St. Ambrose, about the year 374, who was the institutor of the Ambrosian chant, established at Milan about the year 386; and Eusebius (lib. ii. cap. 17.) tells us, that a regular choir, and method of singing the service, were first established, and hymns used in the church at Antioch, during the reign of Constantine; and that St. Ambrose, who had long resided there, had his melodies thence. This was, about two hundred and thirty years afterwards, amended by pope Gregory the Great, who established the Gregorian chant; a plain, unisonous kind of melody, which he thought consistent with the gravity and dignity of the service to which it was to be applied. This prevails in the Roman church even at this day: it is known in Italy by the name of *canto fermo*; in France, by that of plain chant; and in Germany, and most other countries, by that of the *cantus Gregorianus*. Although no satisfactory account has been given of the specific difference between the Ambrosian and Gregorian chants, yet all writers on this subject agree in saying, that St. Ambrose only used the four authentic modes, and that the four plagal were afterwards

added by St. Gregory. Each of these had the same final, or key-note as its relative authentic; from which there is no other difference than that the melodies in the four authentic, or principal modes, are generally confined within the compass of the eight notes *above* the key-note, and those in the four plagal, or relative modes, within the compass of the eight notes *below* the fifth of the key. See *Mode*.

Ecclesiastical writers seem unanimous in allowing, that pope Gregory, who began his pontificate in 590, collected the musical fragments of such ancient psalms and hymns as the first fathers of the church had approved and recommended to the first Christians; and that he selected, methodized, and arranged them in the order which was long continued at Rome, and soon adopted by the chief part of the western church. Gregory is also said to have banished from the church the *canto figurato*, as too light and dissolute; and it is added, that his own chant was called *canto sermo*, from its gravity and simplicity.

It has been long a received opinion, that the ecclesiastical tones were taken from the reformed modes of Ptolemy; but Dr. Burney observes, that it is difficult to discover any connection between them, except in their names; for their number, upon examination, is not the same; those of Ptolemy being seven, the ecclesiastical eight; and, indeed, the Greek names given to the ecclesiastical modes do not agree with those of Ptolemy in the single instance of key, but with those of higher antiquity. From the time of Gregory to that of Guido, there was no other distinction of keys than that of authentic and plagal; nor were any semitones used but those from E to F, B to C, and occasionally A to Bb.

With respect to the music of the primitive church, it may be observed, that though it consisted in the singing of psalms and hymns, yet it was performed in many different ways; sometimes the psalms were sung by one person alone, whilst the rest attended in silence; sometimes they were sung by the whole assembly; sometimes alternately, the congregation being divided into separate choirs; and sometimes by one person, who repeated the first part of the verse, the rest joining in the close of it.

Of the four different methods of singing now recited, the second and third were properly distinguished by the names of *symphony* and *antiphony*; and the latter was sometimes called *responsaria*, in which women were allowed to join. St. Ignatius, who, according to Socrates (lib. vi. cap. 8.), conversed with the apostles, is generally supposed to have been the first who suggested to the primitive Christians in the East the method of singing hymns and psalms alternately, or in dialogue; and the custom soon prevailed in every place where Christianity was established; though Theodoret, in his History (lib. ii. c. 24.), tells us, that this manner of singing was first practised at Antioch. It likewise appears, that almost from the time when music was first introduced into the service of the church, it was of two kinds, and consisted in a gentle inflection of the voice, which they termed plain song, and a more elaborate and artificial kind of music, adapted to the hymns and solemn offices contained in its ritual; and this distinction has been maintained even to the present day.

Although we find a very early distinction made between the manner of singing the hymns and chanting the psalms, it is, however, the opinion of the learned Martini, that the music of the first five or six ages of the church consisted chiefly in a plain and simple chant of unisons and octaves, of which many fragments are still remaining in the *canto sermo* of the Romish missals. For with respect to

music in parts, as it does not appear, in these early ages, that either the Greeks or Romans were in possession of harmony or counterpoint, which has been generally ascribed to Guido, a monk of Arezzo, in Tuscany, about the year 1022; though others have traced the origin of it to the eighth century, it is in vain to seek it in the church. The choral music, which had its rise in the church of Antioch, and from thence spread through Greece, Italy, France, Spain, and Germany, was brought into Britain by the singers who accompanied Austin the monk, when he came over, in the year 596, charged with a commission to convert the inhabitants of this country to Christianity. Bede tells us, that when Austin and the companions of his mission, had their first audience of king Ethelbert, in the isle of Thanet, they approached him in procession, singing litanies; and that afterwards, when they entered the city of Canterbury, they sung a litany, and at the end of it, Allelujah. But though this was the first time the Anglo-Saxons had heard the Gregorian chant, yet Bede likewise tells us, that our British ancestors had been instructed in the rites and ceremonies of the Gallican church by St. Germanus, and heard him sing Allelujah many years before the arrival of St. Austin. In 680, John, preceptor of St. Peter's in Rome, was sent over by pope Agatho to instruct the monks of Weremouth in the art of singing; and he was prevailed upon to open schools for teaching music in other places of Northumberland. Benedict Biscop, the preceptor of Bede, Adrian the monk, and many others, contributed to disseminate the knowledge of the Roman chant. At length the successors of St. Gregory, and of St. Austin his missionary, having established a school for ecclesiastical music at Canterbury, the rest of the island was furnished with masters from that seminary. The choral service was first introduced into the cathedral church of Canterbury, and, till the arrival of Theodore, and his settlement in that see, the practice of it seems to have been confined to the churches of Kent; but after that, it spread over the whole kingdom; and we meet with records of very ample endowments for the support of this part of public worship. This mode of religious worship prevailed in all the European churches till the time of the Reformation: the first deviation from it is that which followed the reformation by Luther, who being himself a lover of music, formed a liturgy, which was a musical service, contained in a work, entitled, "Psalmodia, h. e. Cantica sacra Veteris Ecclesie selecta," printed at Norimberg in 1553, and at Wittenberg in 1561. But Calvin, in his establishment of a church at Geneva, reduced the whole of divine service to prayer, preaching, and singing; the latter of which he restrained. He excluded the offices of the antiphon, hymn, and motet, of the Romish service, with that artificial and elaborate music to which they were sung; and adopted only that plain metrical psalmody, which is now in general use among the reformed churches, and in the parochial churches of our own country. For this purpose he made use of Marot's version of the Psalms, and employed a musician to set them to easy tunes only of one part. In 1553, he divided the Psalms into pauses or small portions, and appointed them to be sung in churches. Soon after they were bound up with the Geneva catechism, from which time the Catholics, who had been accustomed to sing them, were forbid the use of them, under a severe penalty. Soon after the reformation commenced in England, complaints were made by many of the dignified clergy, and others, of the intricacy and difficulty of the church music of those times: in consequence of which it was once proposed, that organs and curious singing should be removed from our churches.

Latimer, in his diocese of Worcester, went still further, and issued injunctions to the prior and convent of St. Mary, forbidding in their service all manner of singing. In the reign of Edward VI. a commission was granted to eight bishops, eight divines, eight civilians, and eight common lawyers, to compile a body of such ecclesiastical laws as should in future be observed throughout the realm. The result of this compilation was a work, first published by Fox the Martyrologist, in 1571, and afterwards in 1640, under the title of "Reformatio Legum Ecclesiasticarum." These thirty-two commissioners, instead of reprobating church music, merely condemned figurative and operose music, or that kind of singing which abounded with fugues, responsive passages, and a commixture of various and intricate proportions; which, whether extemporary or written, is by musicians termed descant. However, notwithstanding the objections against choral music, and the practice of some of the reformed churches, the compilers of the English liturgy, in 1548, and the king himself, determined to retain musical service. Accordingly the statute 2 & 3 Edw. VI. cap. 1. though it contains no formal obligation on the clergy, or others, to use or join in either vocal or instrumental music in the common prayer, does clearly recognize the practice of singing; and in less than two years after the compiling of king Edward's liturgy, a formula was composed, which continues, with scarcely any variation, to be the rule for choral service even at this day. The author of this work was John Marbecke, or Marbeike; and it was printed by Richard Grafton, in 1550, under the title of the Book of Common Prayer, noted. Queen Mary laboured to re-establish the Romish choral service; but the accession of Elizabeth was followed by the act of uniformity; in consequence of which, and of the queen's injunctions, the Book of Common Prayer, noted by Marbecke, was considered as the general formula of choral service. In 1560, another musical service, with some additions and improvements, was printed by John Day; and in 1565, another collection of Offices, with musical notes. Many objections were urged by Cartwright, and other Puritans, against the form and manner of cathedral service, to which Hooker replied, in his Ecclesiastical Polity. In 1664, the statutes of Edward VI. and Elizabeth, for uniformity in the common prayer, were repealed; and the directory for public worship, which allows only of the singing of psalms, established. But upon the restoration of Charles II. choral service was again revived, and has since uniformly continued. The Quakers object to singing as a part of public worship, and accordingly it is never practised in their meetings. To this respectable body we here make an apology for a jeu d'esprit of our learned coadjutor, Dr. B., who compiled part of the article LITURGY, which escaped him, notwithstanding his well-known liberality and candour, and which was undoubtedly unseasonably introduced, in an account of their public worship. Religious scruples, though in some respects unfounded and unwarrantable, when seriously avowed, are not fit subjects of ridicule. See on this subject Hawkins's Hist. of Music, vol. i. p. 404. vol. ii. p. 264. vol. iii. p. 58—468, &c. vol. iv. p. 44—347. Burney's Hist. Mus. vol. ii. ch. i. passim.

*SERVICES of the Church.* (See CATHEDRAL SERVICES.) These have been collected, and splendidly and accurately published in score, by doctors Green, Boyce, and Arnold. These valuable publications appeared in the following order, and are reputable monuments of the abilities of our old masters in the ecclesiastical style of composition, equal, at least, to contemporary productions by the greatest contrapuntists on the continent.

CATHEDRAL MUSIC; being a collection in score of the most valuable and useful compositions for the service by the several English masters of the last 200 years, the whole selected and carefully revised by Dr. William Boyce, organist and composer to the royal chapels, and master of his majesty's band of musicians. Vol. i. 1760.

The second volume was published in 1768, and the third in 1773. These were both dedicated to his majesty.

In 1780, Dr. Samuel Arnold, organist and composer to his majesty's royal chapels, published, in the same splendid manner, a first volume, in continuation of this collection of services and full and verse anthems of old masters; and in 1790 a second and third volume, all dedicated to the king.

There is likewise, in the British Museum, Bibl. Harl. 7337, Plut. VI. B. a collection of English church music, in six vols. 4to. all transcribed for and dedicated to the right hon. Edward lord Harley, by Dr. Thomas Tudway, music professor of Cambridge. In these volumes, among some compositions of no great merit, there are many valuable productions by Tye, Tallis, Bird, Morley, Gibbons, Child, Blow, Purcell and Crofts, that have never yet been published.

*SERVICE, Cathedral.* See CATHEDRAL SERVICE.

*SERVICE-Tree*, in Botany, a corruption of the Latin *SORBUS*; see that article, as well as *PYRUS* and *MESPILUS*.

*SERVICE-Tree, Wild.* See *CRATÆGUS*.

*SERVIENTES VIRGATORES.* See *VIRGATORES*.

*SERVIÈRE*, in Geography, a town of France, in the department of the Lozere; 15 miles N.W. of Mende.

*SERVIERES*, a town of France, in the department of the Correze, and chief place of a canton, in the district of Tulle; 13 miles S.E. of Tulle. The place contains 1115, and the canton 8567 inhabitants, on a territory of 265 kilometres, in 10 communes.

*SERVILE*, in Hebrew Grammar, the denomination of a class of letters used in contradistinction to *radical*. The latter constitute *roots* (which see), and the former constitute derivatives, or branches from these roots, and are employed in all the different flexions. Of all the twenty-two letters of the alphabet, any of which may be radicals, there are properly only eleven letters that can claim this title, because they never can be serviles. The serviles are the other eleven letters, by means of which the whole business of flexion, derivation, numbers, genders, persons, and tenses, is accomplished. But even these letters are somewhat limited in their servile power. For only two of them, *viz.* ך and ם can be inserted or ingrafted between radical letters; the others must be either prefixed or postfixed to the root. The eleven servile letters are the following; ם, ך, ן, ף, ץ, ץ, ץ, ץ, ץ, ץ, ץ.

*SERVIN, LOUIS*, in Biography, a celebrated lawyer in France, who flourished at the sixteenth and beginning of the seventeenth centuries, was descended of a good family in the Vendomois. He cultivated polite literature with success while he was young, and at an early period became the correspondent of several eminent men of letters in different parts of Europe. In 1589 he was appointed advocate-general to the parliament of Paris, being then, according to Vendome, "a young man of great learning, and much attached to the interests of his majesty Henry III." He distinguished himself in that station by his zealous support of the liberties of the Gallican church, and his opposition to the pretensions of the court of Rome. His printed pleadings were honoured with the censure of the Sorbonne, and with a virulent attack by a Jesuit of Provence. The title of his work was "Actions notables et Plaidoyers." In

1590 he published a work in favour of Henry IV., who had succeeded to the crown, entitled "Vindiciae secundum Libertatem Ecclesiae Gallicanae, et Defensio Regii Status Gallo-Francorum sub Henrico IV. Rege." In 1598, being joined in a commission for the reformation of the university of Paris, he delivered "a remonstrance" on the subject, which was printed. To him also is attributed a work in favour of the republic of Venice in the affairs of the Interdict. In the reign of Lewis XIII., at a bed of justice holden in 1620, he made strong and animated remonstrances in favour of the right of parliament to register royal edicts. On another similar occasion, for the purpose of compelling the registry of some financial edicts, as he was firmly but respectfully making fresh remonstrances to his majesty, he suddenly fell and expired at the king's feet, a memorable death, and such, says his biographer, as may in a measure entitle him to be enrolled among the martyrs to liberty. The private character of this excellent magistrate was worthy his high public reputation, and few men of his time stood in more general reputation.

**SERVING**, encircling a rope with line or spun-yarn, &c. to preserve it from the wet getting to it; also to prevent its being chafed. **RIGGING**, *Plate I. fig. 48.*

**SERVING the Rigging.** See **MALLET**.

**SERVING-Mallet**, a cylindrical piece of wood with a handle in the middle. It is used for serving rope, and has a groove along the surface, opposite to the handle, which fits the convexity of the rope to be served. **RIGGING**, *Plate I. fig. 49*, a short board with scores in it, is used for laying on small service.

**SERVISTAN**, in *Geography*, a town of Persia, in the province of Faristan; 25 miles S.E. of Schiras.

**SERVITES**, an order of religious, so denominated from their vowing a peculiar attachment to the service of the Virgin.

The order was founded by seven Florentine merchants, who, about the year 1233, began to live in community on mount Senar, two leagues from Florence. In 1239, they received from the bishop the rule of St. Augustine, with a black habit, in lieu of a grey one, which they had worn before. In 1251, Bonifacio Monaldi, one of the seven, from being simple prior of mount Senar, was named general.

This order was approved of by the council of Lateran, and again by cardinal Raynerius, legate of pope Innocent IV., who put it under the protection of the holy see. The succeeding popes have granted it a great many favours. It is become famous in Italy, by the history of the council of Trent, of F. Paolo, a Venetian, who was a religious Servite. M. Hermant gives this order the name of the Annunciate, doubtless from this mistake, that in some cities of Italy they are called *religious of the Annunciate*, because in those cities their church is dedicated under that name. F. Archang. Giani derives the name Servites, servants of the holy Virgin, from hence; that when they appeared for the first time in the black habit given them by the bishop, the suckling children, as they say, cried out, *Behold the servants of the Virgin*. There are also nuns of this order.

**SERVITIA**, *Per Quæ*. See **PER QUÆ**.

**SERVITIIS Acquietandis**, a writ judicial that lies for a man distrained for services to one, when he owes and performs them to another, for the acquittal of such services.

**SERVITIUS Consuetudinibus**. See **CONSUETUDINIBUS**.

**SERVITOR**, in the university of Oxford, a scholar or student, who attends and waits on another for his maintenance there.

**SERVITORS of Bills**, denote such servants or messengers of the marshal of the king's bench, as were sent abroad with bills or writs, to summon men to that court. They are now commonly called *tip-slaves*.

**SERVITUDE**, the condition of a servant, or rather slave. Under the declension of the Roman empire, a new kind of servitude was introduced, different from that of the ancient Romans: it consisted in leaving the lands of subjugated nations to the first owners, upon condition of certain rents, and servile offices, to be paid in acknowledgment. Hence the names of *servi censiti*, *ascriptitii*, and *addicti glebæ*; some of which were taxable at the reasonable discretion of the lord; others at a certain rate agreed on; and others were manmortable, who, having no legitimate children, could not make a will to above the value of five-pence, the lord being heir of all the rest; and others were prohibited marrying, or going to live out of the lordship. Most of which services still subsist in one province or other of France; though they are all abolished in England. Such, however, was the original of our tenures, &c. See **SLAVE**.

**SERVIVS**, **MAURUS-HONORATUS**, in *Biography*, a grammarian and critic, who flourished in the reigns of Arcadius and Honorius, is principally known by his Commentaries on Virgil, which, however, are considered rather as a collection of ancient remarks and criticisms on that poet than as made by himself. They contain many valuable notices of the geography and arts of antiquity. The Commentaries of Servius were first printed separately at Venice in 1471, and have frequently been reprinted since. In 1532 they were annexed to Stephens's Virgil, but they are most correctly given in Burman's edition in 1756. A tract on prosody by this author, entitled "Centimetrum," is printed in the collections of the ancient grammarians. Servius is mentioned with respect and honour by Macrobius, who makes him one of the speakers in his Saturnalia. *Gen. Biog.*

**SERVIVS**, **SULPICIVS RUFUS**, an eminent Roman jurist and statesman, was descended from the illustrious patrician family of Sulpicii. He was contemporary with Cicero, and born probably about a century before the birth of Christ. He cultivated polite literature from a very early period, especially philosophy and poetry, and wrote some pieces in the latter class, which were marked with the licentiousness of the time. He bore arms in the Marfic war; but finding himself better pleased with the arts of peace, he appeared a pleader at the bar in the 25th year of his age. The professions of advocate and lawyer were then so distinct, that the former were accustomed to consult jurists upon all difficult points. Servius having once applied for that purpose to Quintus Mucius, a very eminent lawyer, the latter perceiving that Servius did not comprehend his explanations, asked him if it were not a shame that he, a patrician and pleader, should be ignorant of the law upon which he was frequently called to speak. This reproach is said to have had such an effect upon him, that Servius quitted the bar, and gave all his attention to legal studies; and such was his success, that Cicero said of him, "If all, in every age, who in this city have acquired a knowledge of the law, were brought together, they would not be to be compared with Servius Sulpicius;" and he farther adds, that "he was not less the oracle of justice than of the law: he always referred to principles of equity and obvious interpretation what he deduced from the civil code, and was less desirous of finding grounds for actions than of settling disputes." There was a great intimacy formed between these two personages, and there are several letters extant from Cicero to Sulpitius, and two from Sulpitius to Cicero, of which

one is a well-known consolatory epistle on the death of Tullia.

Servius passed through the usual gradations of honour among Romans of rank. He was first *quæstor*, then *edile* and *prætor*. When the troubles of the republic were impending, he was created *interrex*, in which quality he nominated Pompey sole consul. He was himself consul with Marcellus, in the year 51 B. C., and opposed the motion of his colleague to remove Cæsar from his command, lest it should immediately bring on a civil war. After the battle of Pharsalia he declared for Cæsar, and was appointed governor of Achaia. When that chief was taken off he returned to Rome, and acted with the party who aimed at the restoration of public liberty. During the siege of Modena by Mark Antony, he was urged by the senate to undertake a legation to him, which, after pleading his age and infirmities, he accepted: but he foresaw it would be fatal to him, and he died in Antony's camp in the year 43 B. C. Cicero's ninth Philippic is entirely employed in pleading for a brass statue to the memory of this excellent man, as for one who had lost his life in the service of the republic, which was voted by the senate. Servius was author of a great number of volumes on legal topics, none of which have been preserved; but quotations from some of them are extant in A. Gellius.

SERVIVS TULLIVS, the sixth king of Rome, was the son of Ocrisia, a native of Corniculum, who was made a captive when the Romans took that place. Tarquin the Elder presented Ocrisia to his queen Tanaquil, and having a son born while she was in a state of servitude, he was named SERVIVS. It is not at all known who the father of this king was, and it was probably not till after his elevation to the regal dignity that he was represented as having been a person of rank who was killed in the defence of his country. Young Servius was brought up in the palace, and became a great favourite of the king and queen. He distinguished himself both in a civil and military capacity; was raised to the patrician order; had an important command in the army given him; and was at length united in marriage to Tarquinia, the king's daughter. On the assassination of Tarquin, Servius took possession of the throne, which event is dated in the year 577 B. C. As the sons of Ancus Martius, who were the authors of the conspiracy against Tarquin, had a strong party among the patricians, Servius pursued the policy of attaching the people to his interest, by paying off their debts, and making several regulations in their favour; and having added to his reputation by a defeat of the revolted Etruscans, he strengthened his title to the crown by procuring a legal election from the *curiæ*. He then applied himself to the improvement of the public police, and several of the most useful institutions of the Roman state took their origin in his reign. Servius enlarged the city by taking two more hills into its limits: he added a fourth tribe to the three old ones: he divided the whole Roman territory into tribes, with a *pagus*, or fortified post to each, and instituted a census, by which all the Roman citizens were distributed into six classes, according to their property. He also gave to the freedmen the privileges of citizens; and finding the duties of the regal office under the augmented population too numerous, he committed to the senate the determination of ordinary causes, reserving to himself only the cognizable crimes against the state. Aware that he was still looked upon by the nobles as an intruder on the throne, he endeavoured to add consequence to his family by marrying his two daughters to the grandson of the late king. He now created a closer connection between the Romans and their allies, the

Latins and Sabines, by the erection of a temple of Diana at Rome, at their common expence, in which they were to join in annual sacrifices, and in the amicable decision of all disputes among them. Servius, in many respects, was fortunate as a man and a monarch; but his greatest calamity was in his youngest daughter, who was continually urging her husband Arunx to criminal attempts against her father, but he nobly rejecting her infamous solicitations, she attached herself to the other brother, her sister's husband, Tarquin, a prince of a character and disposition very similar to her own. They got rid of their partners by poison, and then, having formed an incestuous union, they boldly and openly declared Servius an usurper, and Tarquin laid claim to the throne before the senate. The patricians generally came over to his interest; but the great mass of the people were determined to support their king, who, whatever might have been his descent, had shewn himself worthy of the crown which his infamous relations wished to tear from his head. Tarquin, however, continued to intrigue with his party, and at length took the daring step of assuming the royal robes and insignia, and seated himself on the throne at the temple in which the senate assembled. He there pronounced a violent invective against the person and government of Servius, who arrived while he was speaking, and approached to pull down his son-in-law from the throne; but Tarquin seized the venerable monarch by the waist, and threw him down the steps of the temple. He rose with difficulty, and was moving away by the help of some by-standers, when his unnatural daughter Tullia arrived, who, having saluted her husband as king, suggested to him the necessity of dispatching her own father. Tarquin sent persons to perpetrate the foul deed, and Tullia sealed her cruelty and impiety by driving her chariot over the dead body. Servius was murdered in his 74th year, after a reign of forty-four years, during which he had done enough to merit the title and character of one of the best kings of Rome.

SERVULA, in *Ornithology*, the name of a web-footed sea-bird, a kind of *mergus*, very common about Venice, and called by Mr. Ray *mergus cirratus fuscus*, the brown-crested, or lesser-toothed diver, and supposed to be the *anas longirostris*, or long-beaked duck of Gesner. This is the red-breasted merganser of Pennant.

It is very nearly of the size of the duck; its head and throat are of a fine changeable black and green; on the first there is a long pendent crest of the same colour; the upper part of the neck and of the breast, and the whole belly, white; the lower part of the breast ferruginous, spotted with black; the upper part of the back black; near the setting on of the wings some white feathers, edged and tipped with black; the exterior scapular black; the interior white; lower part of the back, the coverts of the tail, and feathers on the sides, under the wings, and over the thighs, grey, marked with waving lines of black; covers on the ridges of the wings dusky, succeeded by a broad bar of white; the quill-feathers dusky, the tail is short and brown, and the legs orange-coloured; the head and upper part of the neck of the female are of a deep rust colour; the crest short, the throat white, and distinguished by some other varieties of colour from the male. These birds breed in the northern parts of Great Britain. Pennant.

SERUM. See BLOOD.

SERUM *Aluminosum*, *Alum-whey*, a form of medicine prescribed in the late London Pharmacopeia, made of a pint of milk boiled to whey with a quarter of an ounce of alum.

SERVONG, in *Geography*, a town on the N. coast of Sumatra. N. lat. 5° 3'. W. long. 96° 18'.

SERUSKUI,

SERUSKUI, a town of European Turkey, in Romania; 30 miles N. of Gallipoli.

SERWEEZ, a town of Russian Lithuania; 64 miles E. of Wilna.

SERWEL, a province of the Cuttore country.

SERWOY, in *Natural History*, a name given by Theodore de Bry, and others, to the animal called by us the *opossum*, and by the natives of Brazil the *cariguaya*.

SERYA, in *Geography*, a town of Hindoostan, in Oude; 32 miles S.W. of Lucknow.

SESA, a town of Nubia, on the Nile; 210 miles S.S.W. of Syene.

SESAMION, a word used by the ancients to express a preparation of the sesamum, or oily grain. It was a cake made of sesamum, honey, and oil.

SESAMOID, in *Anatomy*, a name given to some small bones of the thumb and great toe. See EXTREMITIES.

SESAMOIDES, in *Botany*, a name first published by Clusius, as applied at Salamanca to two very different plants, neither of them bearing any evident resemblance to *Sesamum*. These are *Silene Otites* and *Reseda sesamoides*; see RESEDA and SILENE. Tournefort has founded on the last-mentioned species, along with *R. canescens* and *purpurascens*, his genus *Sesamoides*, *Inst.* 424. t. 238, whose character depends on the deep divisions of the ripe fruit, each of which embraces a seed, and seems a distinct capsule. But this is only one instance, amongst others, of the proteus-like nature of the very peculiar genus of *Reseda*.

SESAMUM, an ancient Latin name, *σπασμύς* in Greek, for which some vague derivations have been proposed, but which appears, as professor Martyn observes, to have been taken from *Sempsem*, the Egyptian name of the same plant, or grain, the use of which, as food, has been, from the most remote antiquity, common in the East. Those who have read the Arabian tales, will not forget the magic power of the word *Sesame*.—*Linn. Gen.* 323. *Schreb.* 422. *Willd. Sp. Pl.* v. 3. 358. *Mart. Mill. Dict.* v. 4. *Ait. Hort. Kew.* v. 4. 52. *Juss.* 138. *Lamarck Illustr.* t. 528. *Gærtn. t.* 110.—Class and order, *Didymia Angiospermia*. *Nat. Ord. Luridæ*, *Linn. Bignonia*, *Juss.*

Gen. Ch. Perianth inferior, of one leaf, erect, short, permanent, in five deep, equal, lanceolate segments, of which the upper one is shortest. *Cor.* of one petal, bell-shaped; tube roundish, almost as long as the calyx; throat inflated, spreading, bell-shaped, very large, declining; limb in five segments, four of which are spreading, and nearly equal, the fifth, which is the lowermost, ovate, straight, twice as long as the rest. *Stam.* Filaments four, originating from the tube, shorter than the corolla, tapering, ascending, the two innermost shortest; anthers oblong, acute, erect; there is an imperfect filament besides. *Pist.* Germen superior, ovate, hairy; style thread-shaped, ascending, rather longer than the stamens; stigma lanceolate, deeply divided into two parallel plates. *Peric.* Capsule oblong, obscurely quadrangular, compressed, pointed, of two valves and four cells. *Seeds* numerous, nearly ovate.

Ess. Ch. Calyx in five deep segments. Corolla bell-shaped, five-cleft at the border; the lowest segment largest. A rudiment of a fifth filament. Stigma lanceolate, divided. Capsule of four cells.

Obs. Linnæus remarks that the flower agrees with *Digitalis*, but the fruit is widely different.

1. *S. orientale*. Common Sesamum or Oily-grain. *Linn. Sp. Pl.* 883. *Willd. n.* 1. *Ait. n.* 1. (*Sesamum* seu *Sempsem*; *Alpin. Ægypt.* 98. t. 100. *S.* five *Sisamum*; *Ger. Em.* 1232.)—Leaves ovate-oblong, undivided; the lower ones somewhat ferrated.—Native of the East Indies.

VOL. XXXII.

A tender annual, occasionally raised, for the sake of curiosity, in the faves of Europe. The oil of its seeds is much used in Egypt and the East, being preferred to that of the olive. The seeds themselves are also a great article of food. An external application of the herb, either in the form of a fomentation or cataplasm, is supposed to be useful in cutaneous, and various other, disorders. The root is fibrous. *Stem* erect, near two feet high, branched, round, smooth, leafy. *Leaves* opposite, stalked, more or less ovate, one and a half to three inches long, finely downy; paler beneath; the upper ones entire; the lower often coarsely toothed, but not lobed or divided. *Flowers* axillary, stalked, white, about an inch long. *Calyx* and *corolla* hairy. *Capsule* erect, beaked, an inch long, transversely furrowed, rough with minute close-pressed hairs.

2. *S. luteum*. Yellow-flowered Sesamum. *Retz. Obs. fasc.* 6. 31. *Willd. n.* 2.—“Leaves lanceolate, on long stalks. Corolla externally hispid.”—Found by Koenig, in groves at Nidrapur, in the East Indies. The stem is upright, leafy, very little zig-zag. *Leaves* alternate, acute, rough at the edges, as well as the ribs beneath, with very short hairs. *Flowers* axillary, solitary, each on a short stalk, which proceeds from the base of the footstalk itself. *Calyx* and *capsule* hispid. *Corolla* deep yellow. *Retz.*

3. *S. indicum*. Indian Sesamum. *Linn. Sp. Pl.* 884. *Willd. n.* 3. *Rumph. Amboin.* v. 5. 204. t. 76. f. 1 (*S. alterum, foliis trifidis, orientale, semine obscuro*; *Pluk. Phyt.* t. 109. f. 4.)—Lower leaves ternate, or three-lobed, ferrated; upper undivided. *Stem* erect.—Native of the East Indies, Mauritius, &c. Differs from the first species principally in the division of its lower leaves. The flowers are whitish, compared by Rumphius to those of *Hebarte*. Both *calyx* and *corolla* are externally hairy, as in *S. orientale*. There is a variety with black, and another with brown or greyish, seeds. Both are used in Amboyna, but the latter is preferred.

4. *S. laciniatum*. Jagged Sesamum. *Willd. n.* 4.—“All the leaves deeply three-cleft, jagged. *Stem* prostrate, hispid.”—Gathered by Klein, in the East Indies, near Hydrabad.—The stem is branched, the extremities of its branches only ascending. *Leaves* opposite, on short stalks, rough on both sides; whitish beneath; their segments blunt, deeply toothed. *Flowers* axillary, solitary, on very short stalks. *Capsule* obtuse at each end, tipped with the broad permanent style. *Willdenow.*

Both this and the preceding may possibly be mere varieties of the first species. *S. luteum* appears to be distinct.

5. *S. prostratum*. Dwarf Hoary Sesamum. *Retz. Obs. fasc.* 4. 28. (*Euphrasie affinis pusilla planta, pericarpio lignoso oblongo quadrato bivalvi*; *Pluk. Amalth.* 85. t. 373. f. 2.)—Leaves roundish, toothed, hispid; hoary beneath. *Stem* prostrate, villous.—Native of loose sands near Madras; very rare elsewhere. *Koenig, Rottler.* *Root* woody, thick and strong, evidently perennial. *Stems* several, woody at the base, about a span long, much branched, leafy, villous, spreading flat on the ground in every direction. *Leaves* opposite, stalked, small, from one quarter to three quarters of an inch long, obtuse or abrupt, coarsely toothed, often wedge-shaped at the base; the upper surface hairy; lower white and cottony; the upper ones, beyond the flowers, often alternate. *Flowers* axillary, solitary, stalked, thrice as long as the leaves, very handsome. *Corolla* externally shaggy and hoary; internally yellow, beautifully stained and dotted with blood-red. *Capsule* ovate, quadrangular, hard, woody, hairy, scarcely more than half

half the length of the corolla. *Seeds* numerous, oblong, angular, black.

Linnæus has erroneously referred the above synonym of Plukenet to his *Torenia asiatica*, a very different plant. Hence Willdenow was led to omit the present species of *Sesamum*, as very uncertain. *S. javanicum*, Burm. Ind. 133. Retz. Obs. fasc. 4. 28, is *Columnnea longifolia*, Linn. Mant. 90. *Achimenes sesamoides*, Vahl. Symb. v. 2. 71. Willd. Sp. Pl. v. 3. 357.

SESAMUM is also a name given by some authors to the myagrum, or gold of pleasure.

SESBAN, a barbarous and inadmissible generic name, even when altered by Mr. Pursh into *Sesbania*, in his Flora of North America, v. 2. 460, 485. This name is given by Poiret in Lamarck's Dictionary, v. 7. 126, to a genus selected by him out of *ÆSCHYNOMENE*, see that article; and consisting of the Linnæan *Æ. grandiflora*, *coccinea*, and *Sesban*, with several others more recently discovered. These plants are mostly referred by Willdenow to *Coronilla*, with which they do not ill accord. They certainly cannot remain with the original species of *Æschynomene*, which scarcely differ from SMITHIA, see that article.

SESEL, Poiret in Lam. Dict. v. 7. 130, the Amboyna name of a tree, which, according to Rumphius, assumes a very different appearance on the coast to what is usual in the adjacent plains; the leaves, always strongly three-ribbed and entire, lanceolate in the latter situation, being roundish-ovate, and much shortened, in the former. He speaks of this plant as allied to *Metrofaleros*, the wood being so hard as to spoil the tools used in cutting it down. Nothing is known of the fructification, except that the flowers form small whitish heads, subsequently brown, and the fruit seems a globose yellow berry, or drupa. See Rumph. Amboin. v. 3. 64. t. 36, 37.

SESELI, an old Latin name for some plants of the umbelliferous family, which may possibly be included in the present genus. It is *σεισέλι* also in Greek; but no person has been able to give a plausible Greek etymology of the word, which Ray judges to be barbarous, like some other names ending in *i*. De Theis accordingly, on the authority of James Golius, deduces it from an Arabic word which he writes *Sycelyois*.—Linn. Gen. 143. Schreb. 193. Willd. Sp. Pl. v. 1. 1458. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 154. Sm. Prodr. Fl. Græc. Sibth. v. 1. 199. Pursh v. 1. 197. Just. 220. Lamarck Illustr. t. 202.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellifera*.

Gen. Ch. *General Umbel* rigid; *partial* very short, of many rays, globose. *General involucre* of very few leaves, or none; *partial* of several pointed leaves, about the length of the partial umbel. *Perianth* scarcely discernible. *Cor.* *Universal* uniform; florets all fertile; *partial* nearly flat, of five petals, whose inflexed points render them heart-shaped. *Stam.* Filaments five, awl-shaped; anthers simple. *Pist.* Germen inferior; styles two, distant; stigmas obtuse. *Peric.* Fruit ovate, small, striated, separable into two parts. *Seeds* two, ovate, convex and striated at the outer side, flat on the inner.

Eff. Ch. Umbels globose, rather rigid. Flowers regular, all fertile. General involucre of one or two leaves; partial of several. Fruit ovate, striated.

Obf. *S. Hippomarathrum* offers a remarkable exception to the above generic character, having a partial involucre of one leaf, orbicular and toothed, like the wheel of a clock. That of *S. gummiferum* is nearly similar.

1. *S. filifolium*. Thread-leaved Meadow-faxifrage. Thunb. Prodr. 51. Willd. n. 1.—Leaves linear-thread-

shaped. Stem zigzag, erect. Perianth awl-shaped.—Gathered at the Cape of Good Hope, from which we have an authentic specimen. The stem is a foot high, slightly branched, round, furrowed, smooth. Leaves two or three, one of which only remains perfect, an inch long, undivided, very narrow, acute, ribbed, smooth, somewhat channelled. Umbel terminal, of four rigid striated rays, with a general involucre of as many unequal, lanceolate, ribbed, smooth leaves, the longest but half the length of the rays. Partial umbels level-topped rather than globose, of ten or more short stout angular rays, and several lanceolate partial involucre leaves, of the same length. The half-ripe fruit is oblong, about as long as the stalks which support it, furrowed, crowned with a very evident calyx, of five awl-shaped, sharp, permanent, somewhat spinous, teeth, finally recurved at the points. We have been the more particular in our description, as there is no figure of this plant extant, and few botanists would recognize it for a *Seseli*.

2. *S. pinpinelloides*. Nodding Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 2.—Stem declining, and umbels drooping, before flowering. Leaves pinnate; leaflets doubly pinnatifid, with alternate, flat, linear, decurrent segments.—Native of the south of Europe. Cultivated by Linnæus at Upsal. Perennial. Stem a foot high, slightly leafy, round, finely striated, smooth, decumbent at first, but firmly erect as the flowers come to perfection, and bearing about three rather large umbels, which in a young state droop, like those of *Pinpinella Saxifraga*. Radical leaves stalked, a span long, smooth, of a light glaucous green; their segments spreading, acute, entire, veiny, very uniform. Flowers white. Partial involucre of one or two, almost capillary, leaves. Seeds a quarter of an inch long, nearly oval, with five elevated ribs, three of which are central, two marginal, and dark intermediate furrows.

3. *S. montanum*. Mountain Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 3. Ait. n. 1. (*S. multicaule*; Jacq. Hort. Vind. v. 2. 59. t. 129. *Carvisolia*; Vaill. Paris. t. 5. f. 2.)—Footstalks under the branches oblong, entire, with a membranous edge. Stem-leaves with linear very narrow segments. Seeds downy.—Native of hills in Italy and France. Cultivated at Oxford in the middle of the 17th century. A hardy plant, flowering in summer. Root perennial, tapering, crowned with the fibres of decayed footstalks. Stems erect, from one to three feet high, round, striated, smooth, branched, leafy. Leaves doubly pinnate, three-cleft; the segments of the upper ones longest, narrowest, and most glaucous; their footstalks sheathing, close, striated, with more or less of a membranous border, entire at the summit. Umbels smaller than in the preceding, erect, white, of many rays, sometimes accompanied by a general involucre leaf. Seeds obovate, one-fourth the length of the former, ribbed, minutely downy.

4. *S. striatum*. Furrowed Meadow-faxifrage. Thunb. Prodr. 51. Willd. n. 4.—Footstalks under the branches with a membranous edge, emarginate. Stem striated. Leaflets awl-shaped, channelled.—Native of the Cape of Good Hope. Thunberg.

5. *S. glaucum*. Glaucous Meadow-faxifrage. Linn. Sp. Pl. 372. Willd. n. 5. Ait. n. 2. Jacq. Austr. t. 144.—Footstalks under the branches oblong, entire, with a membranous edge. Branches spreading. Leaflets linear, channelled, smooth, glaucous, longer than their footstalks. Seeds ovate, downy. Umbels lax.—Native of France. To define the difference between this plant and *S. montanum* is very difficult. The *glaucum* has longer leaflets, and the primary divisions of its radical leaves seem to be always stalked, not fitting close to the mid-rib. The branches are more divaricated,

cated, and umbels more lax. *Seeds* rather shorter. In Jacquin's figures these plants appear very different, but the *glaucum* of most authors is merely *montanum*. Jacquin does not notice the hairy *seeds*.

6. *S. ariflatum*. Bearded-leaved Meadow-faxifrage. Ait. n. 3. Willd. n. 6. (*Ligusticum lucidum*; Mill. Dict. ed. 8. n. 4.)—"Footstalks under the branches lax, entire, somewhat membranous. Leaves repeatedly compound; leaflets lanceolate, brittle-pointed. Fruit ovate."—Native of the Pyrenean mountains. Cultivated by Miller at Chelsea. A hardy perennial, flowering in June and July. *Aiton*. Miller says the *root* is biennial. *Leaves* doubly pinnate; lobes very narrow, and finely divided. *Stems* strong, a foot and half high, furnished with shining winged leaves, and terminated by pretty large umbels of whitish flowers. A specimen sent by Gouan for *S. annuum*, which it certainly is not, seems to be the plant under consideration. The segments of its *leaves* have callous tips. The leaves of the partial *involucrum* are ovate, with broad white membranous edges, their points extending beyond the *flowers*.

7. *S. annuum*. Caraway-leaved Meadow-faxifrage. Linn. Sp. Pl. 373. Willd. n. 7. Jacq. Austr. t. 55. (*S. carvifolium*; Villars Dauph. v. 2. 586, from the author. *S. coloratum*; Ehrh. Herb. n. 113. Beitr. v. 5. 179. *Pimpinella tenuifolia*; Rivin. Pentap. Irr. t. 83. f. 1. *Fœniculum sylvestre annuum*, tragofelini odore, umbellâ albâ; Vaill. Paris. 54. t. 9. f. 4.)—"Footstalks of the upper leaves lax, membranous, emarginate. Stem and branches erect. Leaves doubly pinnate, cut; their primary divisions sessile. Seeds smooth.—Native of France, Germany, and Switzerland. *Root* tapering, woody, crowned with fibres of decayed leaves, and having all the appearance of being perennial. *Stem* twelve or eighteen inches high, erect, stiff, somewhat zigzag, round, striated, leafy, often purplish; its branches very little spreading. *Leaves* stalked, varying greatly in the length of the leaflets and their divisions, green rather than glaucous; occasionally purplish; their segments linear-oblong, narrow, keeled. *Umbels* white or purplish, of many general as well as partial rays, all more or less downy. Partial *involucrum* of many lanceolate membranous-edged leaves, whose taper points reach beyond the flowers. *Seeds* elliptic-oblong, very convex, with three dorsal ribs, destitute of pubescence in every part. We have this species from M. Du Cros as Haller's n. 762, to which it seems well enough to answer, but if so, Gouan mistakes Haller's plant.

8. *S. cherophylloides*. Chervil Meadow-faxifrage. Thunb. Prodr. 51. Willd. n. 8.—"Footstalks under the branches membranous, tumid, entire. Stem forked, panicled. Leaves repeatedly compound, smooth."—Gathered by Thunberg, at the Cape of Good Hope.

9. *S. Ammoides*. Milfoil Meadow-faxifrage. Linn. Sp. Pl. 373. Willd. n. 9. Ait. n. 4. Jacq. Hort. Vind. v. 1. 20. t. 52. (*Ammoides*; Bauh. Pin. 159. *Ammi*; Matth. Valgr. v. 2. 120. *A. Matthioli*; Dalech. Hist. 695.)—Leaflets of the radical leaves imbricated; those of the upper ones almost capillary. Stem spreading. Rays of the umbel capillary, very unequal. Seeds smooth.—Native of Greece, Portugal, Italy, Sicily, and the south of France. A slender annual plant, about a foot high, its *stem* generally branched from the very bottom. Lower *leaves* on long slender stalks, pinnate, their leaflets in many narrow-lanceolate, channelled segments, lying over each other; upper usually twice ternate, with much longer, and very slender, undivided leaflets; their footstalks short, sheathing, furrowed, and membranous. *Umbels* terminal, very delicate and lax, of about seven or eight extremely unequal capillary rays; the partial ones of more numerous, but like-

wife unequal, much shorter, spreading rays. *Involucral* leaflets bristle-shaped. *Flowers* white. *Fruit* minute, roundish-ovate, striated, smooth.

10. *S. tortuosum*. Crooked Meadow-faxifrage. Linn. Sp. Pl. 373. Willd. n. 10. Ait. n. 5. (*S. massiliense*, fœniculi folio, quod Diofcoridis cenetur; Bauh. Pin. 161. *Fœniculum tortuosum*; Bauh. Hist. v. 3. p. 2. 16.)—Stem much branched, divaricated, rigid, furrowed and angular. Leaves of the partial involucrem ovate, membranous at the edges, somewhat combined at the base.—Native of the south of Europe. *Root* biennial, rather than perennial. This species is known by its remarkably rigid, repeatedly branched, straggling *stem*, bearing great numbers of rigid, clumsy, spreading umbels, each frequently accompanied by a general involucrem of one leaf. The *stem-leaves* are commonly very small, with a large, broad, abrupt, membranous-edged footstalk. Whether the leaflets of the radical leaves vary greatly in length and breadth, or whether Linnæus has, under this, confounded several distinct species, we have not sufficient information to decide. The whole herbage is glaucous, of a thick rigid habit.

11. *S. gummiferum*. Gummy Meadow-faxifrage. Sm. Exot. Bot. v. 2. 121. t. 120. Ait. Epit. 374.—Stem furrowed, rigid, leafy. Partial involucrem of many linear leaves, united by a broad base. Flowers almost sessile. Leaflets wedge-shaped.—Gathered by professor Pallas in the Crimea. It was observed by Mr. Lambert in the Oxford garden, about the year 1803, and communicated by him to his friends. The plant is biennial, hardy, flowering in summer and autumn. *Stem* three or four feet high, erect, branched, leafy, very stout and rigid, furrowed, minutely downy; when wounded exuding a copious, yellow, fetid resinous gum. *Leaves* a span long or more, triply pinnate, glaucous, somewhat downy; their leaflets oblong or wedge-shaped, flat, decurrent, acute. *Umbels* terminal, erect, finely downy, flattish, from three to six inches broad, of very numerous rays. *General involucrem* usually of one short strap-shaped leaf; but in the large primary umbel of several: *partial* with a broad, simple, disk-like base, fringed with copious, horizontal, linear, acute leaflets, nearly equal to the *flowers*. Each partial umbel is flat when young, particoloured with purple and white, but afterwards convex, consisting of innumerable almost sessile flowers, powdered over, as it were, with the white anthers. *Petals* red and white, inflexed, nearly regular. *Germen* furrowed, smooth. *Fruit* elliptical. The *flowers* have a faint smell, not unlike those of the Barberry. In Haller's letters, v. 2. 318, is one from Dillenius, dated Dec. 1746, in which he speaks of an umbelliferous plant, sent under the name of *S. feli* from Siberia, which, being sown in the spring, flowered, but perished on the approach of winter, without producing seed. He conceived it to be allied to the *Hippomarathrum* of Rivinus, (see our next species,) on account of the simple-leaved partial involucrem, cut into six or eight teeth. The general umbel had a slender strap-like leaf to each ray. The seeds resembled those of Caraway, and were not winged. Might not this be our *S. gummiferum*? If so, Dillenius ought to be recorded as its original introducer.

12. *S. Hippomarathrum*. Cupped Meadow-faxifrage. Linn. Sp. Pl. 374. Willd. n. 12. Ait. n. 6. Jacq. Austr. t. 143. (*Hippomarathrum*; Rivin. Pentap. Irr. t. 67. *Saxifraga pannonica*; Clus. Hist. v. 2. 196. Ger. Em. 1047.)—Stem nearly leafless. Partial involucrem of one cup-shaped many-toothed leaf.—Native of stony ground in Austria, Carniola, Hungary, &c. flowering in July and August. The *root* is woody and perennial, crowned with the scaly or fibrous remains of old footstalks. *Stems* a foot

high, nearly upright, rigid, round, smooth, rushy, somewhat branched above, bearing several oblong, sheathing, membranous-edged *footsalks*, with only very short or abortive *leaves*. The proper *leaves* are radical, pretty numerous, stalked, two or three inches long, doubly pinnate and cut, linear, glaucous and smooth like the rest of the herbage. *Umbels* terminal, solitary, small and close, rigid, minutely downy, with several principal rays, and sometimes a sheath-like leaf at the base; the *partial* ones of many white, nearly sessile, *flowers*, chiefly remarkable for the simple, cup-like, partial *involucrum*, whose membranous downy edge is variously jagged and toothed. Dillenius rightly observes, in the letter to Haller, quoted under our last species, that this singular part is not shewn in the figure of Clusius and Gerarde. It indicates an affinity to our *gummiferum*, which obliges us to place these two species together, next to *tortuosum*, with which they accord greatly as to habit.

13. *S. Turbith*. Turbith Meadow-faxifrage. Linn. Sp. Pl. 374. Amoen. Acad. v. 4. 310. Willd. n. 11. (*S. que ferulæ facie*, Thapsia, five Turbith, gallorum; Bauh. Hist. v. 3. p. 2. 45. Boerh. Lugd. Bat. v. 1. 50. Thapsia Diofc; Lob. Ic. 779. *T. tenuifolia*; Ger. Em. 1030.)—Leaves repeatedly three-cleft, divaricated, awl-shaped. General involucrem of one or two awl-shaped leaves; partial of many short, pointed, membranous ones. Seeds villous, the length of the permanent styles.—Native of Spain, and the south of France. The *root* is perennial, thick, discharging a milky juice, which, according to John Bauhin, to whom it was pointed out by his preceptor Rondelet, possesses a valuable purgative quality. *Stem* erect, branched, round, smooth, not so clumsy as in Bauhin's figure. *Leaves* chiefly opposite, with broad sheathing *footsalks*, spreading, repeatedly subdivided into divaricated, slender, awl-shaped segments, crossing each other, and much resembling fennel. *Umbels* terminal, large, of many slender, downy, spreading, general as well as partial, rays. *General involucrem* of very few and short, tapering, scarcely membranous-edged leaves; those of the *partial* ones more membranous, lanceolate, fringed, half the length of the flower-stalks, quite distinct at their base. *Petals* white. *Fruit* ovate, covered with fine hoary dense bristly hairs, and crowned with the long spreading *styles*, very tumid at their base. *Stigmas* obtuse, but hardly capitate.

14. *S. pyreneum*. Pyrenean Meadow-faxifrage. Linn. Sp. Pl. 374. Willd. n. 13. Ait. n. 7. (*Selinum pyrenæum*; Gouan Illustr. 11. t. 5. *Carvi alpinum*; Bauh. Prodr. 84. Lachenal Act. Helvet. v. 7. 332. t. 12.)—Leaves doubly pinnate, with many linear, acute, decurrent, flat segments. Partial involucrem setaceous, equal to the flowers. Seeds smooth, nearly orbicular, with three close central ribs.—Native of the Pyrenées. Miller appears to have cultivated it in 1731. The *root* is perennial, the size of the finger. *Stem* a foot high, erect, furrowed, smooth, scarcely branched, most leafy at the lower part. *Foosalks* long, dilated and sheathing at the base. *Leaves* three or four inches in length, light green, smooth, their leaflets uniform, with linear, alternate, pointed, decurrent, veiny segments. *Umbels* of six or eight unequal rays, without any *general involucrem*; the *partial* ones convex, dense, many-flowered, with a *partial involucrem* of many smooth, slender leaves, almost capillary, distinct at the bottom. *Petals* yellowish, with a purple tinge externally. *Seeds* with a broad, flat, even margin, their centre marked with three close prominent ribs.

15. *S. faxifragum*. Slender Meadow-faxifrage. Linn. Sp. Pl. 374. Willd. n. 14. (*Pimpinella faxifragia tenuifolia*; Bauh. Prodr. 84.)—"Stem thread-shaped, divari-

cated. Leaves doubly ternate, linear. Umbels of about six rays."—Plentiful about the lake of Geneva, according to C. Bauhin, who describes it with an oblong *root*. *Stem* a foot high, green, smooth, striated, bent, divided from the base, and subdivided into slender *branches*. *Leaves* in slender, afterwards almost capillary, segments. *Flowers* few, minute, whitish, in a small umbel. It is not possible to determine any thing from this description, nor have we seen an authentic specimen. Linnaeus saw this species in Burfer's herbarium only. His account agrees with the above, only adding that the partial involucrem leaves are brittle-shaped.

16. *S. elatum*. Tall Meadow-faxifrage. Linn. Sp. Pl. 375. Mant. 357. Willd. n. 15. Ait. n. 8. Gouan Illustr. 16. t. 8.—Stem much branched, round, rigid, very smooth. Leaves twice ternate, with linear, fleshy, distant leaflets. Fruit smooth, ovate, with distant obtuse ribs. Partial involucrem awl-shaped, shorter than the flowers.—Native of Italy and the south of France. Specimens are in the Linnæan collection from Arduins and Gouan, as well as the garden plant alluded to in the letter of Linnæus, cited by Gouan. These, as well as Gouan's figure, prove the present species to vary greatly in luxuriance. The *stem* is from eighteen inches to five feet high, much branched from top to bottom, very smooth, pale at the joints, leafy, the upper part greatly divaricated. *Lower leaves* twice ternate; *upper* quite simple; all linear, very narrow, fleshy, smooth; each leaf, or leaflet, from one to two inches long. *Foosalks* linear, channelled, sheathing, close, with an evident, though narrow, membranous edge. *Umbels* numerous, terminal, of from two or three to ten rays, smooth, without an *involucrem*; *partial* ones of many shortish unequal rays, their *involucrem leaves* slender, but membranous, rarely equal to the flowers. *Petals* white. *Seeds* ovate, gibbous, smooth, by no means tuberculated, though Gouan describes them dotted; each is marked with three slightly prominent ribs, but not bordered. The synonym of Magnol, quoted in Sp. Pl. was afterwards referred by Linnæus to his *Pimpinella glauca*.

17. *S. triternatum*. Yellow Meadow-faxifrage. Pursh v. 1. 197.—"Leaves triply ternate; leaflets linear, elongated. Umbels hemispherical. Partial involucrem of many linear leaves, as long as the flowers."—About the waters of Columbia river, where it was found by governor Lewis, flowering in April and May. The spindle-shaped perennial *root* is one of the grateful vegetables of the Indians, who use it baked or roasted. *Flowers* deep yellow. *Pursh*.

18. *S. junceum*. Rushy Meadow-faxifrage. Sm. Prodr. Fl. Græc. Sibth. n. 698.—Stem much branched, divaricated. *Foosalks* of the stem-leaves very short, and spreading. *Umbels* solitary, simple, of few flowers.—Found in the Greek herbarium collected by Dr. Sibthorp, but without any name, or mention of the place where it was gathered. The *root* appears to be perennial. *Herb* a span high, rigid, smooth, rather glaucous. *Radical leaves* twice ternate, with keeled three-pointed leaflets; those of the stem very small, and as if abortive. *Umbels* small, white.

19. *S. capitosum*. Tufted Meadow-faxifrage. Sm. Prodr. Fl. Græc. Sibth. n. 699.—Stem simple, nearly naked. *Radical leaves* tufted, flat, pinnate, cut; the terminal leaflet three-cleft, decurrent.—Gathered by Dr. Sibthorp, and his companion Borone, on the summit of the Bithynian Olympus. The *root* is thick, perennial, dividing at the crown into many heads. *Stems* from four to eight inches high, simple, scarcely ever divided, erect, straight, stiff and smooth, bearing a solitary leaf only. *Radical leaves* forming a dense tuft, smooth, rigid, of various sizes. The *foosalk* of the stem-leaf has a membranous edge. *General umbel*

of about five rays. *Fruit* cylindrical, obscurely striated, smooth.

*SESELI-Seed*, in the *Materia Medica*, the name of the seed of a plant, called also by some *libanotis*, and growing three or four feet high, with leaves like fennel, but of a paler green. It is a native of warm climates. The seed ought to be chosen moderately large, of a longish shape, heavy, clean, and of a greenish colour, fresh, and of a grateful smell. It affords, by distillation, a very large quantity of an essential oil, and is hot and dry. It incises, opens, and discusses, and is cephalic, neurotic, pectoral, and nephritic. It is good against epilepsies, apoplexies, vertigos, and all disorders of the head and nerves. *Lemery's Dict. of Drugs*.

The seeds of the *seseli Creticum*, or hart-wort of Crete, are diuretic, uterine, and good in all disorders of the breast and lungs. They are given in suppressions of urine, and of the menses, and in all kinds of flatulencies; and are, among the German physicians, a common ingredient in medicines, intended to promote expectoration.

The seed of the French hart-wort, or *seseli Maffliense*, has been esteemed of great virtue in diseases of the head and nerves, in convulsions and epilepsies, and in weakness of the sight. It is also given in electuaries, intended against all disorders of the breast and lungs, in coughs, catarrhs, and asthma, and in obstructions of the liver. Some have recommended it singly, as a medicine of great efficacy against obstructions of the menses; and Schroder tells us, that it has the credit of being an antidote to the poison of hemlock.

The common hart-wort is possessed of the same sort of virtues with the other two, but its seed is more warm and acrid than that of either of them. It is esteemed a very efficacious remedy in obstructions of the menses, and in all disorders arising from indigestion, crudities, and flatulencies. See *SERMOUNTAIN*.

*SESELI Pratense*. See *SANIFRAGE*.

*SESEME-QUIAN*, in *Geography*, a river of the N.W. territory, in the United States of America, which runs into the Illinois.

*SESEN*, or *SESEM*, a town of the principality of Wolfenbüttele; 12 miles S.W. of Goslar.

*SESERINUS*, in *Ichthyology*, a name given by Rondeletius, and some other authors, to a broad and short sea-fish, seeming the same with the lampuga of Italian fishermen; and described by authors in general, and by this very author in another place, under the name of *stromateus*.

*SESHA*, in *Hindoo Mythology*. Images of Naga, or Sefha, in brass, are said to be invoked in cases of ill-health, with appropriate ceremonies, and according to the author of the Hindoo Pantheon, they are very common in India, where the idea of the medicinal virtues of snakes appears to be of very old date. A Hindoo, attacked by a fever, or other disease, makes an image of Naga in brass, clay, or wax, and performs appropriate ceremonies in furtherance of his recovery. Such ceremonies are particularly efficacious when the moon is in the nakshatra, or asterism, called Sarpa, or the serpent. We have observed that the snake, in all mythological language, is an emblem of immortality; its endless figure, when its tail is inserted in its mouth, an astrological mysticism common to Asia and Europe; and the annual renewal of its skin and vigour afford symbols of continued youth, of duration, and eternity; and its supposed medicinal virtues, or life-preserving qualities, may also have contributed to the fabled honours of the serpent tribe. In the mythological machinery of India, Egypt, and Greece, these coincidences are numerous. Some learned writers attribute this universality of serpent-forms to

the early and all-pervading prevalence of sin, its first shape on earth. For some notice of fabulous relations connected herewith, see *KUSA* and *SUPERNA*. With the Hindoos, serpents are not always of ill omen. A day in the Indian kalendar, called "nagapanchami, is sacred to the demi-gods in the form of serpents, who are enumerated in the Padma and Garuda Puranas." Cities, towns, mountains, rivers, men, women, &c. are commonly, among the Hindoos, named after mythological personages. Nagpour, the capital of the rajah of Berar, properly Nagapuri, is after one of the common names of Sefha, as is also a town in Mysore, Naugmungalam, properly Naga-mangala. See *MAN-GALA*.

One of the fables most commonly alluded to in Hindoo writings, is Vishnu reposing on Sefha, and it is a favourite subject with painters. In a beautiful ode, by sir W. Jones, addressed to Lakshmi, the Magna mater of her sectaries, (see *LAKSHMI*), her union with Vishnu is introduced. On this occasion the bride rose from the churned sea, like our Venus, and choosing Vishnu for her husband, the subject of this article formed a nuptial couch for her reception: thus poetically described.

" ——— Love bade the bridegroom rise:—

Straight o'er the deep, then dimpling smooth, he rush'd,

And tow'r'd th'unmeasur'd snake — stupendous bed!—

The world's great mother, not reluctant, led:

All nature glow'd when'er she smiled or blush'd:

The king of serpents hush'd

His thousand heads, where diamond mirrors blaz'd,

That multiplied her image as he gaz'd."

The operation of churning the ocean, alluded to above, is described under the article *KURMAVATARA* of this work, and a poetical allusion to the reflecting gems or mirrors on the heads of Sefha, will be found under *SHITAKOONTHA*. See also *LOTOS*.

*SESHNAGA*, a name of a mighty mythological serpent among the Hindoos, otherwise called *Sefha*; which see.

*SESHTI-MATRIYA*, a name of Kartikya, the mythological commander of the celestial armies of Hindoo fable. The name means having *six mothers*. Shan-matriya has the same meaning, and is another of his names, and Shanmatura. Shanmuka is another, and means with six faces or mouths. For the origin of these appellations, and for some particulars of the hero so distinguished, see *KARTIKYA*, and *SKANDA*, another of his names.

*SESA*, in *Geography*, a river of Italy, which rises in the Alps, on the borders of the Valais, and runs into the Po, a little below Casal.

*SESA*, one of the six departments of France, into which Piedmont was divided, when it was united to the French republic, Aug. 26, 1802; it is composed of Verceil and Mafserans, in N. lat. 45° 25', E. of Doire; and contains 140 square leagues, and 204,445 inhabitants; it was divided into three circles, *viz.* Verceil, comprehending 79,391 inhabitants; Santhia, with 36,014; and Bielle, having 89,040 inhabitants. The climate of this department is unhealthy; the eminences and hills are favourable for the culture of the vine; and the cultivated plains yield abundance of grains, fruits, and pastures.

*SESIAT*, a town on the N.W. coast of Timor. S. lat. 8° 54'. E. long. 125° 26'.

*SESKAR*, a small island in the N. part of the gulf of Bothnia. N. lat. 65° 38'. E. long. 23° 39'.—Also, a small island in the gulf of Finland. N. lat. 59° 57'. E. long. 28° 14'.

SESLERIA, in *Botany*, received that appellation from Scopoli, who in the first edition of his excellent *Flora Carniolicæ*, says, he could never forget the delightful garden, so rich in scarce plants, which he often used to visit, while at Venice, in the year 1745. It was formed in the island of St. Helen, by Dr. Leonard Sefler, whose great diligence in observing and cultivating plants justly entitled him, in Scopoli's opinion, to this botanical commemoration. A letter of his, describing a supposed new genus under the name of *Vitaliana*, is subjoined to Donati's *Storia Naturale del Adriatico*, but Linnæus reduced the plant to *Primula*.—Scop. Carn. ed. 1. 189. Sm. Fl. Brit. ed. Prodr. Fl. Græc. Sibth. v. 1. 52. Ait. Hort. Kew. t. 1. 153. Juss. 31. Lamarck Dict. v. 7. 138. Illustr. t. 47.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. Cal. Glume of two, nearly equal, ovate-lanceolate, concave, pointed valves, containing about three flowers. Cor. of two unequal, erect, parallel, acute, valves; the inner folded, two-ribbed, closed, outer rather the longest, entire or three-cleft. Stam. Filaments three, capillary, longer than the flower; anthers pendulous, oblong, cloven at each end. Pist. Germen superior, ovate; styles two, various in length, capillary, more or less combined; stigmas oblong, cylindrical, feathery. Peric. none, except the corolla, which embraces the seed, but is not attached to it. Seed solitary, ovate, smooth.

Eff. Ch. Calyx of two valves, containing about three florets. Corolla of two valves; the inner cloven; the outer variously pointed. Styles united at their base.

1. *S. cærulea*. Blue Moor-grass. Scop. Carn. ed. 2. v. 1. 63. Fl. Brit. n. 1. Engl. Bot. t. 1613. Knapp Gram. t. 43. Ait. n. 1. Arduin. Spec. 2. 18. t. 6. f. 3—5. Poir. in Lam. Dict. n. 1. Hoff. Gram. Austr. v. 2. 69. t. 98. (*Cynofurus cæruleus*; Linn. Sp. Pl. 106. Willd. Sp. Pl. v. 1. 414. Ehrh. Calam. 14. Mart. Ruft. t. 20. Jacq. Ic. Rar. v. 1. t. 21. Gramen glumis variis; Bauh. Pin. 10. Prodr. 21. Theatr. 158. Scheuchz. Agr. 83. t. 11. f. 9. A, B.)—Spike ovate-oblong, imbricated. Bractæas alternate. Outer petals with three teeth.—Native of mountainous pastures, or calcareous rocks, in various parts of Europe, flowering in the early part of summer. It occurs in Westmoreland and Scotland, but not frequently. The root is perennial, tufted, deeply descending, with long firm fibres. Stems a span or more in height, simple, round, without joints, smooth, naked, except at the base. Leaves linear, obtuse, recurved, broadish, keeled, rough-edged; each with a short, tubular, compressed sheath, and a very minute stipula. Spike terminal, solitary, erect, an inch or inch and half long, of a shining purplish-grey, with solitary, jagged, membranous bractæas, of the same colour, at the base of some of the lowermost spikelets. The spikelets are rather numerous, usually turned one way, and mostly in pairs, each of two or three flowers. Calyx with short awns. Petals ribbed; the outer with three teeth, the middle tooth slightly awned; inner petal with two equal teeth; all the ribs fringed. Styles joined at the lower part only.

2. *S. alba*. White Moor-grass. Sm. Fl. Græc. Sibth. v. 1. 56. t. 72. v. 2. 2. (*Carex dubia*; Sibth. MSS.)—Spike ovate-oblong, imbricated. Bractæas alternate. Outer petals lanceolate, acute, undivided.—Discovered by Dr. Sibthorp, in woods about the village of Belgrad, near Constantinople. The general aspect of this grass, so like some of our common species of *Carex*, with compound androgynous spikes, easily led its learned discoverer to refer it to that genus. He was, at the same time, too accurate to overlook the differences of its generic character; though not sufficiently acquainted with *Sesleria*, to perceive its agreement

herewith. This species is somewhat larger in every part than the foregoing, and has a creeping root, sheathed with the wrinkled bases of old leaves. The stems are twelve or eighteen inches high, and the foliage nearly as tall. Spike of a greenish-white, rather shining, scarcely branched. Spikelets two or three together, stalked. Calyx three or four-flowered, membranous, taper-pointed; the middle florets stalked. Petals membranous, whitish, with green roughish keels; the outer one lanceolate, pointed, undivided; inner cloven a little way down into two sharp-pointed lobes, each of which has its own folded rib or keel. Stamens white, considerably longer than the flowers; anthers pale yellow, drooping. Styles smooth, united throughout, the length of the corolla; stigmas divaricated, awl-shaped, clothed with short pubescence. This *Sesleria* serves greatly to confirm the genus, and to indicate its true essential character.

3. *S. sphaerocephala*. Round-headed Moor-grass. Arduin. Spec. 2. 20. t. 7. Poir. in Lam. Dict. n. 2. Lamarck Illustr. t. 47. f. 2. (*Cynofurus sphaerocephalus*; Jacq. Misc. v. 2. 71. Ic. Rar. t. 20. Willd. Sp. Pl. v. 1. 414. *C. microcephalus*; Hoffm. Germ. 49.)—Spike capitate, globose, bracteated at the base. Outer petals with three teeth; the middle tooth awned.—Native of the loftiest alps of Carinthia, Austria, the Tyrol, &c. A very much more slender plant than either of the former. The root is fibrous. Stem four or five inches high, somewhat quadrangular, bearing one leaf only, at the lower part, which is flat, short and broad, with a long striated sheath, and a more elongated stipula than that of the other species. Radical leaves larger and narrower, folded, numerous. Spike almost globular, the size of a common currant, subtended by two or three opposite, broad, concave, notched, membranous, coloured bractæas, not half its own length. Spikelets imbricated every way, of a blueish-purple, nearly sessile. Each calyx contains two or three florets. The petals are divided as in *S. cærulea*, but the middle segment of the outer one is lengthened out into an awn, of a dark hue, twice or thrice as long as the rest. Wulfen, who communicated this species, and its description, to Jacquin, observed what he supposed a variety, with white flowers, in rather larger spikes, four or five florets in each calyx, and a shorter central awn to the corolla. This seems to be represented in Jacquin's plate, and Hoffmann, after Hænk and Hopp, has made it a distinct species, by the name of *Cynofurus sphaerocephalus*, calling our's *microcephalus*. We do not see sufficiently permanent characters to authorize this. Haller makes another *Sesleria*, at his n. 1447, which is *Poa disticha*, Jacq. Misc. v. 2. 74. Ic. Rar. t. 19. Willd. Sp. Pl. v. 1. 400. Allioni has given it the barbarous appellation of *P. seslerioides*. This plant is unquestionably a true *Poa*, see that article.

SESOSTRIS, in *Biography*, king of Egypt, of whom the accounts are so much mixed with fable, and so obscured by antiquity, that it has been found extremely difficult to form a consistent and probable story. Historians are even divided as to the identity of the name Sesostris with that of some other resembling names in the Egyptian history, and several hold him to be the same with the Sefac or Sheshac of the Hebrew scriptures. The following is regarded as the most probable account of this monarch. He is generally placed by chronologers in the 15th century B.C., and is by some thought to have been the son of Amenophis. Educated in manly exercises with a number of companions, he is said to have been sent, by his father, at an early age, upon an expedition into Arabia; and after subduing that country, into Africa. While engaged in the conquest of the latter, his father died; and his successes having inflamed his ambition, he resolved to grasp at universal empire. Before his

his departure from Egypt, he ingratiated himself with the people by many acts of kindness, and made a division of the country into thirty-six departments, to each of which he assigned a governor. Then having constituted his brother Armais regent, he marched with a numerous army into Ethiopia, which he rendered tributary, penetrating near to the straits of Babelmandeb. As he now perceived that he could not carry on his great designs without a navy, he fitted out two fleets, notwithstanding the aversion of the Egyptians to maritime occupations, one in the Mediterranean and the other in the Red sea. By means of the former he reduced the courts of Phœnicia, Cyprus, and several of the Cyclades, and with the latter he sailed into the Indian gulf, and made himself master of its coasts. Then, pursuing his conquests by land, he is represented as having over-run all Asia, and even as having crossed the Ganges. On his return, he invaded the country of the Scythians and Thracians, in which, however, he lost a great part of his army. It is commonly thought that he left an Egyptian colony at Colchos, but Thrace was his farthest progress westward. On his arrival at Pelusium, after an absence of nine years, laden with spoils, and attended with a vast number of captives, he was received by his brother Armais with pretended joy and submission, though he had formed a plot against him. For this traitorous attempt he expelled Armais from Egypt, and then, disbanding his army, he sat down to the improvement of his country. He erected magnificent temples in all the cities of Egypt, in the building of which none but his captives were employed. He raised obelisks, with inscriptions recording his conquests and revenues. He built a wall of great length, on the eastern boundary of Egypt, to protect it from the incursions of the Arabians, and he dug a number of canals, branching from the Nile in all directions, for the purpose both of commerce and navigation. He is said, in the height of his pride, to have harnessed tributary kings to his chariot, till one of them, pointing out to him the rotation of the wheels, by which each part was successively at top and bottom, brought him to reflection. Becoming blind in his advanced years, he finished his course by a voluntary death.

It may be observed that sir Isaac Newton has endeavoured to prove that Sesostris is the Osiris of the Egyptians, and the Bacchus of the Greeks, as well as the Sefac of scripture. Univer. Hist.

**SESQUI**, a particle often used by old masters and theorists, in *Music*, in the composition of words to express different kinds of measure. They called sesquialter measures those which contain notes equal to one-third more than their usual value; that is, when equal to three notes of less value, instead of two. This happened in what was called *perfect time*, before the use of points or dots, when the breve was equal to three semibreves, the semibreve to three minims, &c.

In Italian treatises by old theorists, sesqui is much used to express a kind of ratio, particularly in different species of triples; that is, when the greater term contains the less once, and some small quantity more; as 3 : 2, when the first term contains the second, and unity over, which is the half of 2. So that if the part remaining be just half the less term, as 4 : 3, the ratio is called *sesqui terza*, or *tertia*; if a fourth, or 5 : 4, the ratio is *sesqui quarta*, and so on to infinity; still adding to sesqui the ordinal number of the less term.

**SESQUIALTER** is a stop in the organ, implying a whole and a half. In large organs this stop has usually five ranks of pipes, each note having one found in unison with the diapason, one with the principal, one with the twelfth, and one with the fifteenth.

**SESQUI-ALTERATE**, *the greater perfect*, which is a triple where the breve is three measures, or semi-breves, and that without having any point or dot annexed to it.

**SESQUI-ALTERATE**, *greater imperfect*, which is where the breve, when pointed, contains three measures, and without any point, two.

**SESQUI-ALTERATE**, *lesser perfect*, which is where the semibreve contains three measures, and that without any point.

**SESQUI-ALTERATE**, *lesser imperfect*, a triple, where the semibreve, with a point, contains three measures, and two without.

According to Buontempi, one may likewise call the triples  $\frac{3}{2}$  and  $\frac{3}{4}$ , sesqui-alterates.

**SESQUI-ALTERATE**, in *Geometry* and *Arithmetic*, is a ratio between two lines, two numbers, or the like, where one of them contains the other once, with the addition of a half.

Thus 6 and 9 are in a sesqui-alterate ratio; since 9 contains 6 once, and 3, which is the half of six, over; and 20 and 30 are in the same; as 30 contains 20, and half 20 or 10.

**SESQUIDITONE**, in *Music*, a concord, resulting from the sounds of two strings, whose vibrations, in equal times, are to each other in the ratio of 5 to 6. See **DITONE** and **INTERVAL**.

**SESQUIDUPLICATE RATIO**, is when of two terms, the greater contains the less twice, and half the less remains; as 15 and 6; 50 and 20.

**SESQUI-OCTAVE**, is a kind of triple, marked  $C_3$ , called by the Italians *nonupla di crome*, where there are 9 quavers in every measure or bar, in lieu of 8.

**SESQUIQUADRATE**, an aspect, or position of the planets, when at the distance of four signs and a half, or 135 degrees, from each other.

**SESQUI-QUARTA**, **DUPLA**, is a kind of triple, marked  $C_3$ , called by the Italians *nonupla di sememinime*, where there are 9 crotchets in each measure, instead of 4; that is, three crotchets to each time.

**SESQUIQUINTILE**, an aspect of the planets, when 108 degrees distant from each other.

**SESQUITERTIONAL PROPORTION**. When any number or quantity contains another once and one-third, they are sesquitertional proportions.

**SESSA**, in *Biography*, an Indian philosopher and mathematician, and the inventor of the game of chess, which he communicated to his sovereign Scheram, who was so pleased with it, that he ordered him to demand what he pleased as a reward for his ingenuity. Sessa asked only for a single grain of wheat to be laid on the first square, two on the second, four on the third, and so on in progression through the sixty-four squares. The king, offended that he should demand so mean a gift, directed that he should have just what he asked, and no more; but upon coming practically to the business, it was, in a very short time, found that all the granaries in the kingdom would not supply the demand. Scheram, astonished at the fact, crowned Sessa with very high honours. He lived about the eleventh century.

**SESSA**, in *Geography*, a town of Naples, in Principato Citra; 23 miles S.W. of Casigliano.

**SESSA**. See **SEZZA**.

**SESSEA**, in *Botany*, a Peruvian genus of plants, dedicated by the authors of the splendid Flora Peruviana, to the honour of a Spanish botanist, named Martin Sesleo, to whom the care of the botanic garden at Mexico was entrusted.—Poiret in Lamarek Dict. v. 7 139. "Ruiz and Pavon, Fl. Peruv. v. 2. 9."—Class and order, *Pentandria Monogynia*. Nat. Ord. *Lurida*, Linn. *Solancee*, Juss.

Gen.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, with five angles, each angle terminating in an oval tooth, permanent. *Cor.* of one petal, funnel-shaped; tube as long again as the calyx; throat globular; limb plaited, in five deep, straight, oval segments, revolute at their margin. *Stam.* Filaments five, inserted towards the middle of the tube, curved and downy at their base, as long as the tube; anthers oval, of two cells. *Pist.* Germen superior, small, oblong; style terminal, thread-shaped, the length of the stamens; stigma of two unequal lobes. *Peric.* Capsule cylindrical, slightly curved, as long again as the calyx, of one cell, and two cloven valves. *Seeds* numerous, imbricated, oblong, compressed, each encompassed with a membranous border.

Ess. Ch. Corolla funnel-shaped. Calyx tubular, with five angles, and five teeth. Stamens simple. Stigma of two unequal lobes. Capsule of one cell and two cloven valves. Seeds numerous, bordered.

1. *S. stipulata*. "Fl. Peruv. v. 2. g. t. 115. f. B."— "Leaves lanceolate, or heart-shaped. Clusters panicled."—Native of cool situations, on the mountains of Peru, flowering in June and July. A *small shrub*, five or six feet high, having the aspect of a *Cestrum*. The branches are straight, leafy, alternate. Leaves alternate, stalked, mostly lanceolate, heart-shaped at the base; others, especially the upper ones, narrower, oval, oblong, entire, pointed, from three to five inches long, and one or two broad, smooth above, white and downy beneath. *Stipulas* at the base of the footstalks, equal to them in length, opposite, large, oval, obtuse, sessile, a little heart-shaped at the bottom, deflexed at the sides, deciduous. *Panicles* terminal, composed of straight, downy clusters, with corymbose stalks, of yellow downy flowers, accompanied by small, awl-shaped, deciduous bractees.

2. *S. dependens*. "Fl. Peruv. v. 2. g. t. 116."—"Leaves oblong, heart-shaped. Clusters very long, pendulous."—Native of the banks of rivers in Peru, flowering in November, December, and January. A *tree*, twenty-five or thirty feet high, agreeing in many respects with the foregoing, but the leaves are very powdery at the back, and the clusters very long, simple, and pendulous, slightly zigzag. The flowers are usually placed three together, in alternate sessile tufts. *Calyx* powdery. *Corolla* with a black tube, and yellowish limb, externally downy. *Capsules* black.

Both species are esteemed emollient anodyne. *Poiret*.

SESSEI, in *Geography*, a town of Bengal; 5 miles N.W. of Doesa. N. lat. 23° 4'. E. long. 84° 58'.

SESSENREUTH, a town of Germany, in the principality of Culmbach; 10 miles N. of Bayreuth.

SESSERRY, a town of Hindoostan, in Oude; 13 miles S. of Lucknow.

SESSILE, in *Botany*, a term applied to any part of the herbage or flowers of a plant, that is not elevated on any kind of stalk; from the Latin *sessilis*, sitting close. Many plants bear *flowers sessile*, sessile flowers, on the branches; very few at the root, like *Crocus*, *Colchicum*, and *Aphytia*. It is not unusual for the fructification, though sessile at the flowering period, to become stalked as the fruit advances toward maturity. The *germen* is so usually sessile, as seldom to require to be so described, it being sufficient to notice a stalked germen, whenever such occurs, as affording mostly an important generic character. For *folia sessilia*, sessile leaves, see LEAF.

SESSILE *Roots*, such tuberous roots as adhere to the base of the stalk. See ROOT.

SESSION, *Sessio*, denotes each fitting, or assembly, of a council.

In quoting councils, we say, in such a session, such a canon, &c.

SESSION of *Parliament*, is a season, or space, from its meeting to its prorogation, or dissolution. See PARLIAMENT.

SESSION, in *Law*, denotes a fitting of justices in court, upon their commission. As the session of oyer and terminer, of gaol-delivery, &c. See ASSISES, JUSTICES of Assise, JUSTICES of Gaol-delivery, JUSTICES of Oyer, &c.

SESSIONS of *Wales*, *Great*. See COURTS of *Wales*.

*Quarter-sessions*, called *general sessions*, or *open sessions*, stand opposite to *especial*, otherwise called *petty sessions*, which are procured upon some special occasion, for the more speedy dispatch of justice. See QUARTER-sessions.

*Statute-sessions*, are those kept by a high-constable of a hundred, for the placing of servants, &c. See STATUTE.

SESSIONS for *Weights and Measures*. In London, four justices from among the mayor, recorder, and aldermen, (of whom the mayor or recorder is to be one), may hold a session to enquire into offences of selling by false weights and measures, contrary to the statutes; and to receive indictments, punish offenders, &c. Char. K. Cha. I.

SESSION, *The Court of*, otherwise called the *college of justices*, is the supreme court in Scotland for all civil causes. It consists of one constant president, who has an annual salary of 1300*l.* and fourteen other judges, at 700*l. per annum* each, who are lords by their office, which they hold by patent *quamdiu se bene gesserint*. The lord high chancellor presides here when present. The king names several other extraordinary lords, who sit, but are not obliged to give attendance, because they have no salaries; but they may vote among the rest.

The court sits from the first of November, old style, to the last of February, and from the first of June to the last of July, all inclusive; which holds of all the inferior courts or judicatories in Scotland. In time of session, or term, they sit from nine o'clock to twelve in the forenoon, every day in the week but Sunday and Monday; sometimes they sit in the afternoon, to end concluded causes, or to hear such long debates as the forenoon was too short to hear, which gives a great dispatch to causes that come before them. The lords, both ordinary and extraordinary, when in the inner house, sit on a semicircular bench in their robes; where the advocates debate their clients' causes before them. There are six principal clerks belonging to this court. Nine of the lords make a quorum in the inner house, otherwise they cannot vote in any case, except such as are referred to one or more of the whole lords; and one of the ordinary lords (the president being always excepted) is weekly appointed judge in the outer house, for discussing of ordinary actions, and has six under clerks to attend him. He meddles with no extraordinary cases, except where it is remitted to him by all the lords, to be discussed in the outer house for dispatch.

That the lords may have time to read informations, petitions, &c. and the suitors be eased of the trouble of going with them to their houses, every lord has a box standing upon a table in the waiting room in the inner house, from two to four o'clock in the afternoon, every day; wherein all who have papers to offer, may put them by a slit in the cover. Each of the principal clerks have also a box, and parties must put in their bills, answers, or informations of causes to be reported, into the clerk of the process's box.

The rolls of the court bring in all causes in their due order. Causes of the greatest consequence are at first advised by the whole lords in the inner house. Other causes are called of course before an ordinary in the outer house, who decides the controversy, if clear, without farther trouble or expence; and, in case of difficulty, takes some little time

to advise it himself, or to advise with the whole lords upon it. And if any of the parties think themselves wronged by the sentence of the ordinary, they may complain to the lords, and get their answer upon a bill.

An appeal lies from this court to the house of lords.

The *lords of session* were first appointed by James I. of Scotland, who selected, among the estates of parliament, a certain number of persons, and distinguished them by this appellation. They were empowered to hold courts for determining civil causes three times a-year, and forty days at a time, in whatever place he pleased to name. James IV. on pretence of remedying the inconveniences arising from the short terms of the *court of sessions*, appointed other judges, called *lords of daily council*. The session was an ambulatory court, and met seldom; the daily council was fixed, and sat constantly at Edinburgh; and though not composed of members of parliament, the same powers which the lords of session enjoyed, were vested in it. At last, James V. erected the new court that still subsists, and which he called the *college of justice*, the judges or senators of which were called *lords of council and session*. Robertson's Hist. of Scotland, 1776, 8vo. vol. i. p. 40.

SESSIONS, *Kirk*. See *KIRK*.

SESSLACH, in *Geography*, a town in the duchy of Wurzburg; 50 miles N.E. of Wurzburg.

SESSOAH, a town of Bengal; 21 miles S. of Doefa.

SESTA, a town of the Ligurian republic; 5 miles N.W. of Brugnatto.

SESTA, Ital. the interval and consonant of the sixth, in *Musick*. See *HEXACHORD*, and *HEXACHORDON*.

SESTERCE, SESTERTIUS, a silver coin, in use among the ancient Romans, called also simply *nummus*, and sometimes *nummus sestertius*.

The sesterce was the fourth part of the denarius, and originally contained two asses and a half.

The sesterce was at first denoted by LLS; the two L's signifying two libræ, and the S half. But the librarii, afterwards converting the two L's into an H, expressed the sesterce by HS.

The word *sestertius* was first introduced by way of abbreviation for *semisestertius*, which signifies two, and a half of a third, or, literally, only half a third; for in expressing half a third, it was understood that there were two before. Hence *sestertius* came to be the great estimate of Roman money.

Some authors make two kinds of sesterces: the less, called *sestertius*, in the masculine gender; and the great one, called *sestertium*, in the neuter: the first, that which we have already described; the latter containing a thousand of the other. Others will have any such distinction of great and little sesterces unknown to the Romans: *sestertius*, say they, was an adjective, and signified *as sestertius*, or two asses and a half; and when used plurally, as in *quinquaginta sestertium*, or *sestertia*, it was only by way of abbreviation, and there was always understood *centena, millia, &c.*

This matter has been accurately stated by Mr. Raper, in the following manner. The substantive to which *sestertius* referred is either *as*, or *pondus*; and *sestertius as* is two asses and a half; *sestertium pondus*, two pondera and a half, or two hundred and fifty denarii. When the denarius passed for ten asses, the sesterce of two asses and a half was a quarter of it; and the Romans continued to keep their accounts in these sesterces long after the denarius passed for sixteen asses; till, growing rich, they found it more convenient to reckon by quarters of the denarius, which they called *nummi*, and used the words *nummus* and *sestertius* indifferently, as synonymous terms, and sometimes both together, as *sestertius nummus*; in which case, the word *sestertius* having lost its original

signification, was used as a substantive; for *sestertius nummus* was not two nummi and a half, but a single nummus of four asses. They called any sum under two thousand sesterces so many *sestertii* in the masculine gender; two thousand sesterces they called *duo* or *bina sestertia*, in the neuter; so many quarters making five hundred denarii, which was twice the sestertium; and they said *dena, vicena, &c. sestertia*, till the sum amounted to a thousand sestertia, which was a million of sesterces. But, to avoid ambiguity, they did not use the neuter *sestertium* in the singular number, when the whole sum amounted to no more than a thousand sesterces, or one sestertium. They called a million of sesterces, decies nummum, or decies sestertium, for decies centena millia nummorum, or sestertiorum (in the masculine gender), omitting centena millia, for the sake of brevity. They likewise called the same sum decies sestertium (in the neuter gender) for decies centies sestertium, omitting centies for the same reason; or simply decies, omitting *centena millia sestertium*, or *centies sestertium*; and with the numeral adverbs, *decies, vicies, centies, millies*, and the like, either *centena millia*, or *centies*, was always understood. These were their most usual forms of expression; though for *bina, dena, vicena sestertia*, they frequently said *bina, dena, vicena millia nummum*. If the consular denarius contained sixty grains of fine silver, it was worth somewhat more than eight-pence farthing and a half sterling; and the as, of sixteen to the denarius, a little more than a half-penny. To reduce the ancient sesterces of two asses and a half, when the denarius passed for sixteen, to pounds sterling, multiply the given number by 5454, and cut off six figures on the right hand for decimals. To reduce *nummi sestertii*, or quarters of the denarius, to pounds sterling; if the given sum be consular money, multiply it by 8727, and cut off six figures on the right hand for decimals; but for imperial money, diminish the said product by one-eighth of itself. Phil. Trans. vol. lxi. part ii. art. 48. See *DENARIUS* and *DRACHM*.

To be qualified for a Roman knight, an estate of four hundred thousand sesterces was required; and for a senator, of eight hundred thousand.

Authors also mention a copper sesterce, worth about one-third of a penny English.

SESTERCE, *Sestertius*, was also used, in *Antiquity*, for a thing containing two wholes and a half of another: as *as* was taken for any whole, or integer.

SESTINI, *La SIGNORA*, in *Biography*, engaged as a prima buffa in the comic opera, arrived in England from Lisbon in 1774; and her first performance was in Aufossi's comic opera, entitled "La Marchesa Giardiniera." Her face was beautiful, her figure elegant, and her action graceful. Her voice, though by nature not perfectly clear and sweetly toned, had been well directed in her studies, and she sung with considerable agility, as well as taste and expression.

She was married to a young man of family at Lisbon, by which imprudent step he had totally lost all parental favour, and even support; so that, instead of being an auspicious match for herself, she had him and a large family to maintain by her talents; which not being of the first class, were soon disregarded by the public. And after languishing some years unemployed, she went with her helpless husband and family to Italy, where, it is to be feared, they suffered all the melancholy mortifications of extreme indigence.

SESTO, CESARE, known by the name of *Cesare Milanese*, was a native of Milan, and flourished about the year 1500. He is one of those painters by whom probably were executed some of the many pictures attributed to Lionardo da Vinci; and in the Ambrosian library was a head by him often attributed to Lionardo. In some of his works he also

imitated Raphael, to whom he was known. He died at Milan in 1524.

SESTO, in *Geography*, a town of Italy, in the Milanese; 28 miles W.N.W. of Milan.—Also, a town of Italy, in Friuli; 5 miles N. of Concordia.

SESTOLA, a town of Italy, in the department of the Panaro; 17 miles S. of Modena.

SESTOS, a fortress of European Turkey, in the province of Romania, opposite to Abydos; 24 miles S.S.W. of Gallipoli. N. lat.  $40^{\circ} 6'$ . E. long.  $26^{\circ} 25'$ . *Abydos* (which see) and *Sestos* were two towns, opposite one another at the most narrow part of the Hellespont: they were famous for the love-adventures of Leander, who lived at Abydos, and Hero, a priestess of Venus, at Sestos. Leander swam across the Hellespont to visit his mistress, guided by a torch, which she lighted on the top of a tower; but, in a tempestuous night, Leander, having too imprudently committed himself to the waves, could not reach the other shore, and was unfortunately swallowed up by the agitated waters. Hero, in true despair, threw herself into the sea, in order to share the fate of her lover. Procopius places Sestos in the cove the nearest to Abydos; and he adds, that the emperor Justinian caused a citadel to be built near that city: the remains of this citadel are still to be seen close to the sea-shore. On the declivity of the hill, the walls of the ancient city may very easily be traced. Four miles from Sestos, on ascending the channel, is another harbour, near which is seen only a single habitation of dervises, occupied by three or four Mussulman monks.

SESTOS, a river which rises in the mountains of Sierra Leone, traverses the Grain Coast, and runs into the Atlantic, N. lat.  $5^{\circ} 30'$ .

SESTRE, *Grand*, or *Great Paris*, a town of Africa, on the Grain Coast, being one of the largest commercial towns of the country. N. lat.  $4^{\circ} 16'$ . W. long.  $8^{\circ} 20'$ .

SESTRE, *Petit*, or *Little Paris*, a town of Africa, on the Grain Coast, near Grand Sestre.

SESTRE-KRO, or SETTRA-KROO, a town of Africa, being the chief town of the Kroo country, which extends along the Grain Coast, between Cape Mount and Cape Palmas, from  $5^{\circ} 54'$  to  $5^{\circ} 7'$  N. lat. The chief town is in long.  $7^{\circ} 48'$ . This district, though small, is extremely populous, and the natives are of a migratory disposition. Above 800 are employed as labourers at Sierra Leone; and they are to be found at every factory and town along the coast for a space of 350 miles. They are employed as factors or intermediate merchants, boatmen and sailors; and while the slave trade was carried on upon this coast, they had their share of its occupations. After the age of forty, they return and settle at home. Their country produces grain, particularly fine rice, pepper, and cattle; but their staple article is their own labour, with which they purchase goods, and return to their homes with the produce. Wars are rare among this people; they never sell one another, nor kill their captives; nor do they punish any offence by slavery, though witchcraft among them is a capital offence, and the only one that is invariably so among them. One of the most singular parts of the character of the Kroomee, is their extreme love for their own country, and their confident belief in its vast superiority over all others. Every action of their lives bears a reference to it. With regard to their talents and acquirements, they are sufficiently acute and observant, where the occasion calls their minds into action. They have not the use of letters, nor will they permit their children to learn; their language in conversation is very bad; and as they live by daily labour, which is paid for in European goods,

they have no occasion for manufactures of their own, and of course no opportunity for displaying their talents. They make their own canoes, some implements of agriculture, and a few musical instruments.

SESTRI *di Levante*, a town of the Ligurian republic; 12 miles W. of Brugnatto.

SESTRI *di Ponente*, a town of the Ligurian republic; 4 miles W. of Genoa.

SESTUPLA, Ital. in *Music*. See SEXTUPLA.

SESVAH, or RAMGUR, in *Geography*, a town of Hindoostan, in Bahar; 22 miles E.S.E. of Bettiah.

SESVIUM, in *Botany*, a Linnæan name, whose derivation we are unable to trace. Loeffing originally called it *Halimum*.—Linn. Gen. 250. Schreb. 338. Willd. Sp. Pl. v. 2. 1009. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 205. Jacq. Amer. 155. Swartz Obf. 204. Juss. 316. Lamarck Dict. v. 7. 141. Illustr. t. 434.—Class and order, *Icosandria Trigynia*. Nat. Ord. *Succulentæ*, Linn. *Ficoidea*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, deeply cloven into five, ovate, acute, withering segments, coloured on the inside. Cor. none. Stam. Filaments numerous, awl-shaped, shorter than the calyx and inserted at its base; anthers roundish. Pist. Germen superior, oblong, at the bottom of the calyx, triangular at the upper part; styles mostly three, capillary, erect, the length of the stamens; stigmas simple. Peric. Capsule ovate, of three cells, bursting all round. Seeds rounded, flattish, with a beak at the margin.

Ess. Ch. Calyx deeply five-cleft, coloured. Petals none. Capsule ovate, three-celled, bursting all round, many-seeded.

1. *S. Portulacastrum*. Purslane-leaved Sefuvium. Linn. Sp. Pl. 684. Jacq. Amer. t. 95. (Portulaca aizoides maritima procumbens, flore purpureo; Sloane Jam. v. 1. 204. Crithmus indicus; Rumph. Amboin. v. 6. 165. t. 72. f. 1.)—Stem round. Leaves opposite, oblong. Flower-stalks solitary, much shorter than the leaves.—Native of the West Indies, in maritime situations; flowering in July and August.—Root perennial. Stems succulent, four or five inches long, round, thick, diffuse, branched, at first procumbent, then erect. Leaves on short stalks, fleshy, bright green; their stalks sheathing, with membranous edges. Flowers solitary, axillary, green on the outside, white and blood-red or purple on the inside, inodorous. Seeds black.—The whole plant is very succulent, and abounds with a neutral-alkalescent salt, which is easily extracted, and would probably serve as a substitute for *Kali*.

2. *S. revolutifolium*. Revolute-leaved Sefuvium. "Orteg. Pl. Decad 2. 19." Lamarck Illustr. t. 434. f. 2.—Stems square. Leaves obovate-oblong, reflexed at the sides. Flowers sessile.—Native of the isle of Cuba, flowering in August. Stems herbaceous, succulent, much branched, forked. Leaves opposite, stalked, entire, revolute at their edges; stalks slightly embracing the stem, furnished on each side with a whitish membrane, like a wing. Flowers solitary, the upper ones perfectly sessile, of a purple colour. Seeds kidney-shaped, black.

SET, a term used for a pole or shaft, used to shove boats along a canal, &c.

SET is also a term signifying to let, as land.

SET, in *Agriculture* and *Gardening*, a term used in Ireland to signify a sort of ridge. It also signifies a cutting of any sort of fleshy root, shrub, or tree of the fruit kind. Likewise any sort of young plant from the seed-bed to be planted out.

SET-off, in *Law*, is an act, by which the defendant acknowledges

knowledges the justice of the plaintiff's demand on the one hand; but, on the other, sets up a demand of his own, to counterbalance that of the plaintiff, either in the whole, or in part: as, if the plaintiff sues for ten pounds due on a note of hand, the defendant may set-off nine pounds due to himself for merchandize sold to the plaintiff; and, in case he pleads such set-off, must pay the remaining balance into court. This answers very nearly to the *compensatio*, or floppage, of the civil law, and depends upon the statutes 2 Geo. II. cap. 22. and 8 Geo. II. cap. 24.

**SET-off**, in *Inland Navigation*, is a reefs, as I K (*Plate I. Canals, figs. 3 and 6.*), on the bank of a canal, and has the same meaning with bench or berm.

**SET-Bolts**, in a *Ship*. See **BOLTS**.

**To SET sail**. See **SAIL**, and **SETTING**.

**SETACEUS VERMIS**, in *Natural History*, a name given by Dr. Lister to that long and slender water-worm, which so much resembles a horse-hair, that it has been supposed by the vulgar to be an animated hair of that creature. These creatures, supposed to be living hairs, are a peculiar sort of insects, which are bred and nourished within the bodies of other insects, as the worms of the ichneumonflies are in the bodies of the caterpillars. See **AMPHIBÆNA Aquatica**.

**SETAH**, in *Botany*, a name used by the oldest writers for the acacia. It is an original Hebrew word, and is explained by the lexicographers, by a thorn growing in the desert. It is rendered by Theodotion *acantha*, one of the names of the acacia.

**SETAPOUR**, in *Geography*, a town of Hindoostan, in Golconda; 30 miles N.N.W. of Rachore.

**SETARIA**, in *Botany*, from *seta*, a bristle, a name given by Acharius, in his *Prodromus Lichenographiæ Suevicæ*, to the 27th tribe of the great genus *Lichen*. It comprehends seven species, of what have usually been termed filamentous lichens, as *zubatus*, *chalybeiformis*, &c. See **LICHENES**.

**SE-TCHEOU**, in *Geography*, a city of China, of the first rank, in Koei-tcheou, in a mountainous country, yielding cinnabar and quicksilver; 982 miles S.S.W. of Peking. N. lat. 27° 10'. E. long. 108°.

**SE-TCHIN**, a town of China, of the second rank, in Quang-fi; 1167 miles S.S.W. of Peking. S. lat. 22° 48'. E. long. 136° 31'.

**SE-TCHING**, or **SE-TCHIN**, a city of China, of the first rank, in Quang-fi; 1100 miles S.S.W. of Peking. N. lat. 24° 17'. E. long. 105° 54'.

**SE-TCHUEN**, a province of China, bounded on the N. by Chen-fi, on the E. by Hou-quang, on the S. by Koei-tcheou, and on the W. by the kingdom of Thibet and some other neighbouring countries. This province comprehends, besides a great number of forts and strong places, 10 cities of the first class, and 88 of the second and third. The great river Yang-tse-kiang traverses Se-tchuen, which is opulent, not only on account of the abundance of silk it produces, but also for its mines of iron, tin, and lead; its amber, sugar-canes, loadstone, lapis lazuli, musk, and horses, which are in great request; also for its rhubarb, and the root sou-lin, which the Chinese physicians introduce into all their prescriptions; and for a thousand other useful productions, which it would be tedious to mention. This province, which is at a great distance from the sea, obtains the salt which it consumes from its mountains, where the inhabitants dig pits, that furnish them with it in great abundance. Its capital is *Tching-tou*; which see. The population of this province, according to sir John Staunton, is estimated at 27,000,000

**SETEEF**, a town of Africa, anciently called *Sitipha*, and capital of a part of Mauritania, which made a stout resistance against the Saracens. There is scarcely one fragment left, either of the ancient walls, pillars, or cisterns of the Romans; the few remaining structures being obviously the work of the later inhabitants. The fountains, which continue to flow very plentifully near the centre of the city, are equally delightful and convenient; and without doubt gave occasion formerly for many ingenious and useful contrivances in the distribution of the water; 50 miles S.W. of Conitantina. N. lat. 35° 58'. E. long. 5° 36'.

**SETERRA**, or **SETRES**, a town of Africa, on the Grain Coast.

**SETHIANS**, **SETHEDIANS**, *Sethiani*, or *Sethiniani*, in *Ecclesiastical History*, a branch of the ancient Gnostics; thus called, because of their pretending to deduce their origin from Seth, son of Adam, whom they called Jesus and Christ; from an opinion, that Seth and Jesus were the same person, who came down from heaven at two several times.

As the Sethians had the same philosophy with the other Gnostics, they had numerous other fables in their system. They pretended to have several books of the ancient patriarchs; particularly, seven of their great master Seth; besides one of Abraham, which was full of manifest falsities, which yet they called *Apocalypse*, or *Revelation*. The book called the "Little Genesis," anciently very common in the churches of the East, was borrowed from them. From this book they learned the name of Seth's wife, who, they say, was called *Horaa*. Some imagine, they borrowed a great many of their fictions from the Hellenist Jews.

**SETHRON**, in *Geography*, a town of Egypt, on the S. coast of the lake Menzaleh; 16 miles W. of Tineh.

**SETICAUDÆ**, in *Natural History*, a term used to express such flies as have one or more hairs growing out at their tails. There are many species of these distinguished by their having one, two, or three hairs.

**SETIER**. See **SEPTIER**.

**SETINES**, in *Geography*. See **ATHENS**.

**SEIO**, a mountain in the E. part of the Tyrolese.

**SETLANA**, a town of Hindoostan, in the circar of Sirowy; 35 miles N.W. of Sirowy.

**SETLE'**, a town of Turkish Armenia; 30 miles S.W. of Akalziké.

**SETLEDGE**, a river of Hindoostan, which rises in the mountains of Thibet, and runs into the Indus, near Veh, anciently called *Hesudrus*.

**SETON**, a river of Spain, which runs into the Gallego, in the province of Aragon.

**SETON**, *Setaceum*, denotes, in *Surgery*, a skein of silk or thread, introduced through a part of the flesh by means of a needle, and left there so as to keep up a continual discharge of matter, and a degree of counter-irritation, with a view of relieving or curing a variety of diseases. In a few cases, setons are employed on another principle. When sinuses and fistulæ have lost all disposition to heal, in consequence of a want of action in the parts affected, a seton, passed through the track of the disease, will sometimes excite a salutary kind of inflammation, which brings on the healing process. Great judgment, however, is necessary in the application of a seton to this purpose; for, unless the sinus be prevented from healing merely by the cause above specified, namely, a want of action in the parts, no success can be expected to attend the practice, and the patient will be put to much unnecessary pain and inconvenience.

A seton is also sometimes employed as a means of discharging

charging the contents of large chronic abscesses. It is thought by some practitioners that this method has the advantage of letting the matter escape very gradually, a circumstance, by which the dangerous effects, often arising from emptying the abscess all at once, are in a great measure avoided. Many surgeons even suppose that setons hinder the external air from getting into the cavity of the abscess, and, as prejudice and exaggeration have filled their minds with serious apprehensions upon this subject, they are perhaps more attached to the practice than any recommendations which it really possesses would justify.

Formerly, setons were frequently used for accomplishing the radical cure of the hydrocele. The celebrated Mr. Pott was an advocate for this method, which he certainly brought to great perfection. It is scarcely necessary for us to remark here, that the seton excited the requisite degree of inflammation in the cavity of the tunica vaginalis testis, and the adhesion of its opposite surfaces to each other. See **HYDROCELE**.

The common mode of making a seton is with a flat broadish needle, which is somewhat curved towards the point, and furnished with cutting edges. This form enables the surgeon to bring the needle out of the part again without any difficulty. The integuments are pinched up into a fold, of which the operator raises one end with the fore-finger and thumb of his left hand, while an assistant raises the other. The needle, armed with the silk or thread dipped in sweet oil, is then to be pushed through the skin thus lifted up. It is only necessary to draw the end of the silk or thread a little way out of the second aperture: the needle may now be removed. The next object is to fix the ends of the silk, which is usually done with adhesive plaster. The wounds are then to be covered with pledgets, and a retentive bandage. The oil prevents the silk from adhering to the flesh, and facilitates its passage through the wound; for, as soon as suppuration has taken place, that part of the silk which is in the wound is to be drawn out and cut off. The same method is to be repeated every day, and the same plan of dressing continued. When the skein of silk is exhausted, a new one, oiled in the above manner, is to be introduced by means of an eye-probe.

Setons, unless kept exceedingly clean, and dressed with much tenderness, sometimes excite a great deal of irritation, and prove very troublesome to the patient. The thread is also apt, with the least neglect, to cut its way out, and leave an ugly sore.

When a seton is made in a case of large chronic abscess, a puncture is first made in the upper part of the tumour; an eye-probe, armed with a skein of silk, is introduced downward; and the end of the instrument being felt against the inside of the lower part of the swelling, an incision is made upon it, so that the end of the silk can then be drawn out.

The manner of making a seton for the cure of hydroceles has been described in a former volume. See **HYDROCELE**.

The like operation is frequently practised on horses, &c. and called, by the farriers, *rowelling*.

**SETOSCH**, in *Geography*, a town of Bohemia, in the circle of Chrudim; 8 miles S.S.W. of Chrudim.

**SETRA-JETA**, the name, in Hindoo romance, of the father of one of the favourite wives of the popular deity Krishna. Her name was Satyavama; and she is sometimes said to have been an incarnation of Lakshmi, consort of the god Vishnu. See those articles.

**SETS**, in *Agriculture and Gardening*, a term applied to

the cuttings or planted parts of potatoes, hops, liquorice, lavender, &c.

It has lately been found to be of material consequence for the sets which produce the plants, in some cases, to have a large substance for their early nourishment and support, as in those of the potatoe; as though the small parts, called *eyes* or *buds*, will grow and produce crops, they are far from being equal to those where the sets are of a large size. In short, the result of various experiments has shewn that crops of this sort prove, *ceteris paribus*, abundant or otherwise, nearly in proportion to the size of the sets. Therefore, as there is no material saving produced by the use of small sets or cuttings of this root, while the difference in the quantity of produce is from one hundred to one hundred and fifty bushels the acre, the practice of employing such small sets in planting should be discontinued in all situations; and for the very same reason that heavy well-fed corn, when otherwise in good condition, should, in all cases and circumstances, be preferred to that which is light. See **POTATOE** and **SEED**.

**SETSE**, in *Botany*, the name of a Chinese tree, called also *chiuse*, and much esteemed by the people of that country for its beauty, and for the goodness of its fruit. In the provinces of Cantong and Honan there are whole plains covered with these trees, many of which grow to the size of our walnut-tree. The fruit ripens every where in the East, where the tree grows, but it is of a much more delicious flavour in some places than in others. The leaves are of the colour and shape of those of the walnut-tree, only that they are more round at the ends. The fruit is sometimes round, sometimes pointed at one end, sometimes oval, sometimes flat, and not unfrequently composed of two pieces, as it were, and resembling two apples, cut and joined together. The rind is always green, never changing yellow or red, and the fruit keeps its freshness all the winter. They are about the size of the orange, and the skin is very tender and thin, and the fruit has a mixed taste of the sharp and the luscious. It is very wholesome and good.

**SETTE'**, in *Geography*, a town of Africa, and capital of a country of the same name, subject to Loango, on the river Sette; 160 miles north of Loango.—Also, a country of Africa, south of cape Lopez Gonfalso, watered by a river of the same name. This country is governed by a man, who is subject to the king of Loango.—Also, a river of Africa, which runs into the Atlantic, S. lat. 2° 15'.

**SETTEE**, in *Sea Language*, a vessel, very common in the Mediterranean, with one deck, and a very long and sharp prow. They carry, some two masts, some three, without top-masts. They have generally two masts, and are rigged and navigated like xebecs or galleys, with settee sails instead of lateen sails. The least of them are of sixty tons burden. They serve to transport cannon, and provisions for ships of war, and the like. These vessels are peculiar to the Mediterranean sea, and are usually navigated by Italians, Greeks, or Mahometans.

**SETTEFRATRI**, in *Geography*, a town of Naples, in Abruzzo Ultra, 10 miles N. E. of Teremo.

**SETTENIL**, a town of Spain, in the province of Grenada; 8 miles N. of Ronda.

**SETTER**, among *Farmers*. *To setter*, is to cut the dew-lap of an ox, or cow, and into the wound to put the root of the helleboraster; by which an issue is made, for ill humours to vent themselves.

**SETTER-Wort**, in *Botany*. See **HELLEBORE**.

**SETTIA**, in *Geography*, a province of the island of Candia, occupying the whole eastern part of the island; it is the most extensive, but the least peopled, and the least productive,

productive, though in a great measure susceptible of culture, and though most of its lands are very fertile. But distance from the capital, want of harbours, and the inconsiderate injustice of the agas, and almost every other circumstance, contribute to render the inhabitants of this part of the island more indolent than the others. Contented with gathering corn and fruit for their subsistence, oil for paying their taxes, and procuring for themselves a few clothes, and the utensils necessary for their family, they are not eager to seize from the earth a surplus of productions, which would render them more subject to the oppression and spoliation of the agas. The town is situated on a flat shore, which with a cape not much advanced, and three islets placed at upwards of a league's distance, protect it feebly from the N. and N.E. winds. When the Venetians were masters of the island, it was tolerably well fortified, and sufficiently peopled. They constructed a mole, in order to shelter the vessels which came thither to load with the productions of the province, or which brought those that were necessary to supply the wants of the inhabitants. At this day none but small boats may be seen at Settia. The population has diminished considerably, and the fortifications are in the greatest disorder. It is the see of a Greek bishop; 44 miles E.S.E. of Candia. N. lat. 35° 3'. E. long. 26° 3'.

**SETTIAVERAM**, a town of Hindoostan, in the circuit of Cicacole; 30 miles S.W. of Cossimcotta.

**SETTIMA**, Ital., in *Musick*, the interval of the seventh; which see.

**SETTIMANA SANTA**, Ital., passion-week, during which holy time, the sacred music of the highest class used to be performed in the most perfect and impressive manner in the pontifical chapel. See MISERERE and ALLEGRI.

**SETTIMO**, in *Geography*, a town of France, in the department of the Po; 8 miles N. of Turin.—Also, a town of Italy, in the department of the Tesino; 5 miles N.N.E. of Pavia.

**SETTING**, in *Astronomy*, the withdrawing of a star or planet; or its sinking below the horizon.

Astronomers and poets make three different kinds of setting of the stars: cosmical, acronichal, and heliacal.

To find the times of the setting of the sun and stars, see **GLOBE**.

**SETTING**, in *Seamanship*. To set the land, or the sun, by the compass, is to observe how the land bears on any point of the compass, or on what point of the compass the sun is; likewise the act of observing the situation of any distant object by the compass, in order to discover the angle which it makes with the nearest meridian: as at seven *post* meridian, we set the tower of Arabia near the port of Alexandria, and it bore S.S.E. distant four leagues by estimation. (See **BEARING**.) Also, when two ships sail in sight of one another, to mark on what point the chased bears, is termed *setting the chase by the compass*.

**SETTING** also denotes the direction of the wind, current, or sea, but particularly the two latter; as, the tide, which sets to the south, is opposed to a swelling sea, setting to the north-west.

**SETTING**, when applied to the sails, is the loosening and expanding them, so as to give the ship motion, or to accelerate her velocity, when she is already moving, and perhaps give a new direction to her motion. It is used in contradistinction to taking-in the sails, as loosening or heaving-out is opposed to furling or stowing them.

**SETTING**, in the language of *Sportsmen*, a term used to express a manner of attacking partridges, in order to the taking of them by means of a dog peculiarly

trained to that purpose. The setting-dog generally used is a long land-spaniel, taught by nature to hunt partridges more than any other game, and in his untaught state running over the fields in search of them, with an alacrity that is truly wonderful; yet by art this creature is brought under such excellent command, that he will, in the midst of his highest career, attend to the least hem from his master, and stand still to look in his face, and take his orders by the slightest signals; and when he is so near his game, that it is almost in his mouth, he will stand still, or lie down on his belly till his master arrive, and he receives his directions.

The setting-dog being taken to the haunt of the partridges is to be cast off, and sent to range; but he must be made to keep near the sportsman, and not to run wildly on, but to beat all the ground regularly. On being reproved for ranging too widely and too far, he will keep close the whole day, and at times look up in his master's face, to know if he does right or wrong. If in the dog's ranging he stop of a sudden, the sportsman is to make up to him, and as there is certainly game before him, he must be ordered to advance; if he refuses this and look back and shake his tail, it is a signal that they are close before him, and the sportsman is then to take a circumference, and look with a careless eye before the dog's nose to see where they are, and how they lie; then going up, and flaking down one end of the net, he is to command the dog to lie still, and to draw the net gently over the birds; then making in with a noise, he is to spring them, and they will be entangled and taken as they rise. It is a rule with fair sportsmen, when they take a covey in this manner, always to let the cock and hen go.

**SETTING**, among *Cock-Masters*, is the placing a cock that has fought so that he cannot stand, beak to beak against the other cock, and if he does not strike, the battle is won.

**SETTING-down**, in *Falconry*, is when a hawk is put into mew.

**SETTING-dog**, one trained up to find out and discover to the sportsman whereabouts fowls are. See **SPANIEL** and **DOG**.

**SETTING-up**, in *Ship-Building*, is raising a ship by shores and wedges from her blocks, the act of extending the shrouds, stays, and back-stays, to secure the masts, by the application of tackles, &c.

**SETTING**, or *Setting-to*, the act of making the planks, &c. lay or set close to the timbers, by driving wedges between the plank, &c. and wrain-staff. Hence "set, or set away," means to exert more strength. The power or engine used for this purpose is simple, and called a *sett*, and is composed of two ring-bolts, and a wrain-staff, cleats and lashing, or shores.

**SETTING**, in *Agriculture and Gardening*, the business of putting sets of different kinds into the ground, as those of the potatoe, hop, madder, liquorice, lavender, and many other kinds.

**SETTING out Plants**, the practice of thinning and reducing them; in the former, to their proper distances, in order to stand for crops, as in the turnip, cabbage, and many other sorts of plants; and, in the latter, the business of putting them into the ground as crops; it being practised for a great many different sorts of plants that are raised on seed-beds, as all the cabbage kind, lettuces, endives, hearts, and many other plants of a similar nature. It is usually performed as soon as the plants have acquired a proper state of growth in the seed-beds, and mostly when the weather is cloudy and rather moist, as it can then be done to the greatest

greatest advantage, in so far as the plants are concerned. They are commonly put out in this way to the proper distances for growing as crops, and the work is for the most part done by means of a line and dibble. See **THINNING out Crops**, and **TRANSPLANTING**.

**SETTING of Wheat**, is a method of cultivating wheat, which was probably first suggested by planting grains in a garden from mere curiosity, and first attempted on a larger scale by a farmer near Norwich, about the year 1768. His example was followed by some of his neighbours, and particularly by one of the largest occupiers of land in the county of Norfolk, who set fifty-seven acres in one year. His success, from the visible superiority in his crop both in quantity and quality, was so great, that the following autumn he set three hundred acres, and afterwards continued the practice. The method of setting was generally introduced, in consequence of this experiment, among the intelligent farmers, in a very large district of land. And it has been observed, in recommendation of it, that, although the set crops appear very thin during the autumn and winter, the plants tiller and spread prodigiously in the spring. The ears are indisputably larger, without any dwarfish or small corn; the grain is of a larger fathom, and specifically heavier *per bushel* than when sown. It furnishes employment for aged persons and children, at a season when they have little else to do; it saves to the farmer six pecks of seed-wheat in every acre; the expence is already reduced to about six shillings an acre; and a drill-plough has been invented, by which one man may set an acre a day.

The lands on which this method particularly succeeds, are either after a clover stubble, or those on which trefoil and grass-seed were sown the spring before the last, and on which cattle have occasionally pastured during the summer. These grounds, after the usual manuring, are once turned over by the plough in an extended slag or turf, at ten inches wide; along which a man, who is called a dibbler, with two setting-irons, somewhat bigger than ram-rods, but considerably bigger at the lower end, and pointed at the extremity, steps backwards along the turf, and makes the holes about four inches asunder every way, and an inch deep. Into these holes, the droppers (women and children) drop two grains, which are quite sufficient. After this, a gate, bushed with thorns, is drawn by one horse over the land, and closes up the holes. By this mode, three pecks of grain are sufficient for an acre; and being immediately buried, it is equally removed from vermin, or the power of frost. The regularity of its rising affords the best opportunity of keeping clear from weeds, by weeding or hand-hoeing.

**SETTING**, a term used in sheep-management, which signifies the picking, choosing, and selecting those which are the best formed, and most perfect for the purposes of breeding, forming the flock, and keeping as stock; the others, or the refuse ill-formed sheep, being sold off, or sent to be fattened in the proper pastures. The practice is extremely useful and necessary, where good stock of this kind is aimed at, as it cannot be well obtained without it. See **SHEEP**, and **SORTING Sheep-Stock**.

**SETTING Lamb-Stock**, a term made use of to signify the practice of culling and removing those lambs, which are any way improper for being kept as stock. It is an excellent custom in sheep-management, which should be as seldom as possible neglected.

**SETTING of Farms**, the business of letting them to tenants of different kinds. Much care and attention are necessary in the management of this business. See **LETTING Farms**.

**SETTING of Bricks**. See **BRICKS**.

**SETTING-Pin**, the name of a dibble or setting-tool.

**SETTING-Stick**, the stick used in setting out plants or cuttings as field crops, and in putting in and planting out those used for garden culture.

**SETTLE**, in *Geography*, a market-town in the parish of Giggleswick, west division of the wapentake of Staincliffe and Ewicrofs, West Riding of Yorkshire, is situated at the distance of 58 miles W. by N. from York, and 232 miles N.W. by N. from London. The position of this town, though singular, is pleasant, standing close to the base of an almost perpendicular lime-stone rock, about 300 feet high; from the summit of which is a fine prospect of an extensive vale, bounded on all sides by craggy mountains. This vale, which is watered by the river Ribble, and hence has acquired the appellation of Ribblesdale, is not surpassed by any in England in richness of verdure. As the prevalence of fogs and rains prevents the ripening of corn, it is almost wholly appropriated to pasturage; and such is its fertility, that the greater part of it rents as high as six pounds an acre. According to the parliamentary returns of 1811, Settle township contains 274 houses, and 1153 inhabitants, who are chiefly engaged in the cotton manufacture, and in the pursuits of husbandry. Like most of the other towns and villages in this district, it is principally built of stone, brick being used only for the chimnies. The market day here is Friday, weekly; and the fairs are on Tuesday before Palm Sunday, Thursday before Good Friday, and every alternate Friday till Whitfunday, 26th April, 2d June, 18th and 21st August, first Tuesday after 27th October, and every other Monday throughout the year. These fairs are generally well attended, and are noted for large supplies of cattle.

About a mile to the N.W. of Settle is the village of Giggleswick, which gives name to the parish, and where the church is accordingly situated. This village is remarkable for an excellent free grammar-school, founded in the reign of Edward VI., and supported by rich endowments in land. At present the salary of the master is 500*l.* *per annum*, that of the usher 200*l.*, and that of the writing-master 150*l.*; and each has a good house, garden, and every convenience for a comfortable dwelling. Near Giggleswick is a spring, which exhibits the singular phenomenon of a constant influx and reflux of its waters at irregular periods, sometimes thrice or oftener in an hour. No satisfactory explanation of this singularity has yet been offered to public notice.

At the distance of several miles further to the N.W. from Settle, on the road to Kendle in Westmoreland, stands Ingleton, a large village, the vicinity of which presents many objects worthy the attention of the admirers of romantic scenery. Among these are Thornton-Scar, Yordas Cave, and Weathercote Cave, and the mountains of Ingleborough, Pennigant, and Wharnside. Thornton-Scar is a tremendous chasm, above 300 feet in depth, which extends a considerable way into the mountains, and is so narrow towards the bottom, that the sides in some places approach within a few feet of each other. Yordas Cave is situated under a mountain, called Greg-roof. It is entered through a rude arched opening, resembling the gateway of an ancient castle, and extends about 170 feet in length, 40 in breadth, and 48 in height. On one side are several recesses, and the roof and walls exhibit a variety of petrifications. Weathercote Cave displays scenery still more romantic and sublime. It is of a lozenge form, and divided into two by a grotesque arch of lime-stone rock; the total length about 200, and the breadth about 90 feet. At the south

south end is an entrance down into a small cave, which communicates with the larger one by a subterraneous passage, "where the astonished visitant sees, issuing from a large aperture in the rock, an immense cataract, falling above 20 yards in an unbroken sheet, with a noise that stuns the ear. The water disappears as it falls from the rocks and pebbles, and runs about a mile under ground. The whole cave is filled with the spray that arises from the cataract, and sometimes a small vivid rainbow appears, which for colour, size, and situation, is scarcely any where else to be equalled."

But the most sublime features of this romantic district are the mountains of Ingleborough, Pennigant, and Wharnside. The summit of Ingleborough is level and horizontal, and, from its great elevation, commands extensive prospects on all sides. To the east, the picturesque country of Craven presents a confused assemblage of hills, gradually diminishing in height till they vanish in the horizon. Pennigant, at the distance of four miles, appears to be almost within a leap; as do also the rocks of Settle and Pendlehill. The northern and north-western prospect exhibits a mass of mountains. Wharnside is within the distance of six miles, and Snowdon and Crowsell are clearly visible in the background. Towards the west the flat country of Lancashire lies as in a map, and the prospect extends far into the Irish sea, the nearest point of which is 24 miles from Ingleborough. Beauties of England and Wales, vol. xvi. by John Bigland, 8vo. 1813.

**SETTLEMENT**, *Act of*, in *British History*, a name given to the statute 12 & 13 W. III. cap. 2. by which the crown was limited to his present majesty's illustrious house; and some new provisions were added, at the same fortunate era, for better securing our religion, laws, and liberties; which the statute declares to be the birth-right of the people of England, according to the ancient doctrine of the common law. See *Right of Crown*.

**SETTLEMENT**, *Marriage*. See **MARRIAGE**.

**SETTLEMENT** of the Poor. See **POOR**.

**SETTLING a Deck**, at Sea, a term for taking a deck lower than it was at first.

**SETTLING the Land**, denotes sinking it lower, by sailing farther out to seaward, and is used in the same sense with *laying the land*.

**SETTOREE**, in *Geography*, a town of Bengal; 56 miles N.W. of Burdwan.

**SETTOVITONE**, a town of France, in the department of the Dora; 4 miles N. of Ivrea.

**SETTS**, powers made use of, where force is required, to bring or unite two or more pieces together. The operation is performed by screws, shores, cross-setts, or clects.

**SETTS**, *Cross*, are made by two short pieces of spars, about four or six feet in length: one is laid across on the upper side, and the other on the under side, of any two pieces that are to be brought together, and their ends lashed together on each side with several turns of rope, taken round each end alternately: wedges are then driven in between the upper cross-piece, and the side or part of the mast.

**SETTS for Saws**, instruments for setting their teeth, when out of order.

**SETUNA**, in *Geography*, a town of Africa, on the Grain Coast.

**SETUVAL**, or *St. Ubes*, a strong sea-port town of Portugal, in the province of Estremadura, situated in a bay of the Atlantic, at the mouth of the river Sandao, with a good harbour, capable of receiving any ships of burden. This town was founded on the ruins of the ancient Cedo-

briga, which was destroyed by the Moors. The environs abound in corn, wine, and oil. Besides the old walls and towers, it is strengthened with eleven whole and two demi-bastions, with several other out-works. It has likewise a strong citadel, called "St. Philip," in which is a spring of excellent water; and the strong fort of Outao, near the harbour, which also serves for a light-house, exclusive of which it has two smaller forts. It contains four churches, two hospitals, ten convents, an academia problematica, founded by John V., and about 10,000 souls. In 1796, the number of vessels which entered this harbour was 558; and the same number sailed from it; 15 miles S.S.E. of Lisbon. N. lat. 38° 29'. E. long. 8° 53'.

**SETWELL**, in *Botany*, a name sometimes used for a species of valerian.

**SETZINI**, in *Geography*, a town of Poland, in the palatinate of Sandomirz: near it are some silver mines, and some lapis-lazuli; 16 miles W. of Malogocz.

**SEV**, a river of Russia, which runs into the Desna, near Trubchevsk, in the government of Orlov.

**SEU**, a river of Malacca, which runs into the Chinese sea, N. lat. 6° 45'. E. long. 10° 10'.

**SEVAJEE**, in *Biography*, a distinguished person in the history of Hindoostan, the founder of the modern Mahratta empire, was the son of Shawjee, who, from an humble situation, had raised himself by his talents to be guardian to a minor of the house of Nizam Shah. On a Mogul invasion of the country, being closely pursued by the troops of his father-in-law, Jadoo Row, with whom he was at enmity, Shawjee escaped with an infant son, and left his pregnant wife to fall into the hands of her father. She was kindly received, and was delivered of her second son, Sevajee, the subject of this article, in the month of May 1626, and finally separated from her husband.

Sevajee, at the age of 17, placed himself at the head of a body of banditti, who pillaged all the neighbouring districts, which so affected the person who had been entrusted with the care of his education, that he put an end to his life. Upon this, Sevajee took possession of the property accumulated from his father's estate, and increased the number of his followers, so as to become a most formidable free-booter. His exploits soon rendered him dangerous to the government of Vijiapour, which sent a powerful army against him, and brought him to submission. Sevajee asked pardon for his offences, and, by the humility of his deportment, threw the general, sent against him, off his guard, till he found an opportunity to stab him to the heart with a concealed dagger: in consequence of which the army dispersed. Shawjee, the father of this desperate young man, was now high in office at Vijiapour, and though he pretended entirely to have renounced his son, a correspondence between them was suspected, and a plan was formed for seizing his person, and putting him to death. He was, however, saved by the intercession of a patron, and at length restored to office. But he was resolved to have ample revenge for the affront, and caused Sevajee to murder the chief who had seized him, and his whole family. After this Shawjee paid a visit to his son at Poona in great state, and manifested much affection and respect for him.

Sevajee now proceeded in a career of successful predatory war, and in 1664 pillaged the rich city of Surat. Having, in 1672, laid the king of Golconda under a heavy contribution, he afterwards entered into an alliance with a potentate against the Mogul and the king of Vijiapour, the object of which was the expulsion of all the Mahometan powers from the Deccan; and marching with a great army, in 1677, towards Golconda, he took possession of many fortresses,

fortresses, and pillaged the whole country. His half-brother, Eccojee, was now king of Tanjore; and the different branches of the family were possessed of a large portion of the south of India.

The principal dominions of Sevajee were in the tract called Concan, extending from the south of Surat to the south of Goa, which rendered him completely master of the western Gaults; from which he was, at all times, able to issue and ravage the plain country, while it was impossible to force him from his fastnesses; hence he was denominated by Aurungzebe the mountain rat. Sevajee continued this course of action till his death in 1680, when he was succeeded in his conquests by his son Sambajee.

SEVANI, in *Geography*, a town of Persian Armenia, on a lake; 40 miles E. of Erivan.

SEVASTOPOL, a sea-port town of Russia, in the province of Tauris, on the coast of the Black sea, with an excellent harbour for men of war; 80 miles S. of Pereltop. N. lat.  $44^{\circ} 45'$ . E. long.  $33^{\circ} 24'$ .

SEUBELSDORF, a town of Germany, in the principality of Culmbach; 6 miles N. of Culmbach.

SEUBITZ, a town of Germany, in the principality of Culmbach; 8 miles S.S.E. of Bayreuth.

SEUCKENDORF, a town of Germany, in the margravate of Anspach; 4 miles E. of Langenzen.

SEUDRE, a river of France, which runs into the sea, opposite the isle of Oleron, N. lat.  $45^{\circ} 49'$ . W. long.  $1^{\circ} 5'$ .

SEVE, a town of France, in the department of the Seine and Oise, celebrated for its manufacture of china;  $1\frac{1}{2}$  post S.W. of Paris.

SEVEKTEN, or SEVEKOTE, a town of France, in the department of the Lys; 10 miles S.W. of Bruges.

SEVEN, a river of Yorkshire, which runs into the Derwent.

SEVEN AGES, rocks in the Caribbean sea, near the S.E. coast of the island of Blanca.

SEVEN BROTHERS, a cluster of small islands near the north coast of Hispaniola. N. lat.  $19^{\circ} 53'$ . W. long.  $72^{\circ} 35'$ .

SEVEN CAPES. See *SEBBA Rous*.

SEVEN HEADS, a promontory of the county of Cork, Ireland, west of Courtmasherry bay, and 6 miles W.S.W. of the old head of Kinfale. N. lat.  $51^{\circ} 34'$ . W. long.  $8^{\circ} 41'$ .

SEVEN ISLANDS, a cluster of small islands in the East Indian sea. S. lat.  $1^{\circ} 9'$ . E. long.  $105^{\circ} 21'$ .

SEVEN ISLANDS, a cluster of islands near the west coast of Sumatra, lying off Padang.

SEVEN ISLANDS, a cluster of small islands in the English Channel, near the coast of France. N. lat.  $48^{\circ} 54'$ . W. long.  $3^{\circ} 23'$ .

SEVEN ISLANDS, a republic so named, lately formed by the union of the islands of Zante, Cephalonia, Corfu, Cerigo, Curzola, St. Maura or Leucadia, and Teaki, constituted about the year 1799, acknowledged by the Ottoman Porte, and by the French and Great Britain, at the peace of Amiens, 1802.

SEVEN ISLANDS, small islands of Virginia, in James river. N. lat.  $37^{\circ} 40'$ . W. long.  $78^{\circ} 32'$ .

SEVEN ISLANDS, a cluster of small islands near the coast of Canada, in the gulf of St. Lawrence. N. lat.  $50^{\circ} 10'$ . W. long.  $66^{\circ} 5'$ .

SEVEN ISLANDS' BAY, a bay of Canada, on the north side of the river St. Lawrence. N. lat.  $50^{\circ} 5'$ . W. long.  $66^{\circ} 25'$ .

SEVEN PAGODAS, a town of Hindoostan, in the Carnatic; 30 miles S. of Madras.

SEVEN ROCKS' POINT, a cape in the English Channel, on the coast of Dorsetshire; 3 miles S.W. of Lyme Regis.

SEVENAER, or ZEVENAER, a town of Germany, in the duchy of Cleves; 10 miles N. of Cleves.

SEVENBERGEN, a town of Dutch Brabant; 8 miles N.W. of Breda.

SEVENNES, or CEVENNES, mountains of France, crossing the department of the Lozere, particularly memorable as being the strong hold of the Protestants in the 17th century, and beginning of the 18th.

SEVENOAKS, or SEVENOKE, a market-town, in a parish of the same name, hundred of Codsheath, lathe of Sutton at Hone, and county of Kent, England, is situated on high ground at the distance of 16 miles W. by N. from Maidstone, and 33 miles S.E. from London. In the *Textus Roffensis* the name is written Seauanacca, and is said to have been suggested by the circumstance of a cluster of seven large oaks growing on the site of the town, at the time of its foundation. The principal building here is the church, which forms a conspicuous object for several miles round the country. It formerly contained a chantry chapel, founded by sir Henry Gawdy, who was buried within it. The only monument of note is that of William Lambard, the celebrated Kentish antiquary, whose family had a seat in this parish. Here are an alms-house and free-school, originally built and endowed by sir William de Sevenoke, in the beginning of the 15th century. They were subsequently incorporated under the title of the free grammar-school of queen Elizabeth, and now possess a revenue of nearly 1000*l.* a-year. The school-house was rebuilt in 1727, at which time the alms-house was substantially repaired. The former has six exhibitions to either university, and the latter affords an asylum to thirty-two elderly trades-people, who have a weekly allowance in money. This town consists chiefly of two wide streets, in one of which stands the ancient market-house, where the assizes were frequently held during the reign of queen Elizabeth, and where the petty sessions for the lathe of Sutton at Hone are still held. Many of the houses are large and respectable mansions, inhabited by independent families. The market-day here is Saturday, weekly; and there are two annual fairs on the 10th of July and the 22d of October. Seven-oaks town and parish constitute a liberty, governed by a warden or bailiff and four assistants, who are not, however, empowered to hold any court of record for pleas. According to the parliamentary returns of 1811, this liberty contains 638 houses and 3444 inhabitants, of whom about 1500 reside in the town. *History and Topographical Survey of Kent*, by Edward Hasted, 8vo. 1797, vol. iii. *Beauties of England and Wales*, vol. viii. by E. W. Brayley, 8vo. 1805.

SEVENTH, SEPTIMA, in *Music*, an interval, called by the Greeks *heptachordon*; of which there are four kinds.

The first, the *defective* or *diminished* seventh, consisting of three tones, and three greater semitones, as from *ut* sharp to *fi* flat: its ratio is 128 to 75.

The second, called by Zarlino, and the Italians, *semitono con diapente*, or *settimo minore*, is composed diatonically of seven degrees, and six intervals, four of which are tones, and the rest greater semitones, as from *de* to *ut*; and chromatically of ten semitones, six of which are greater, and four less: it takes its form from the ratio *quadrupartiens quintas*, 9 to 5.

The third, called by the Italians *il ditono con diapente*, or *settimo*

*settimo maggiore*, is composed diatonically, like the former, of seven degrees, and six intervals, six of which are full tones, and a single one a greater semitone; so that only one greater semitone is wanting of the octave; as from *ut* to *fi*: and chromatically of eleven semitones, six of which are greater, and five lesser. It takes its origin from the ratio of 15 to 8.

The fourth is the *redundant* seventh, composed of five tones, a greater semitone and a lesser, as from *fi* flat to *la* sharp: so that it only wants a comma of an octave; that is, so much as it wants to render its second semitone a greater. Hence many confound it with the octave itself; maintaining, with good reason, that only the three first sevenths can be of any use.

In thorough basses the seventh, whether double, simple, major, or minor, is marked by a figure of 7; but if it be accidentally flat, or minor, thus,  $\flat 7$ , or  $7 \flat$ . If sharp, major, thus,  $\sharp 7$ , or  $7 \sharp$ . Again, if when it is naturally minor, it be marked with a flat, it must be diminished. See FUNDAMENTAL.

SEVERAC *le Chateau*, in *Geography*, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Milhau; 21 miles E. of Rodés. The place contains 2113, and the canton 6051 inhabitants, on a territory of  $212\frac{1}{2}$  kilometres, in 7 communes. N. lat.  $46^{\circ} 19'$ . E. long.  $3^{\circ} 9'$ .

SEVERAL, in *Agriculture*, the same as dole. See DOLE.

SEVERAL Tail, or *Inheritance*, in *Law*. See INHERITANCE.

SEVERAL Tenancy, *Tenura separalis*, a plea, or exception taken to a writ that is laid against two persons as joint tenants, who are *several*.

SEVERALTY, *Estates in*. He that holds lands or tenements in severalty, or is sole tenant of them, is he who holds them in his own right only, without any other person being connected with him in point of interest, during his estate therein.

SEVERALTY Land, in *Agriculture*, such as is in an open field state, and divided amongst many. It is a bad situation or tenure of land, and ought to be done away as soon as possible.

SEVERANCE, in *Law*, the *singling* or *severing* two or more that join, or are joined, in the same writ or action.

As if two join in a writ, *de libertate probanda*, and the one be afterwards nonsuited; here severance is permitted, so as, notwithstanding the nonsuit of the one, the other may severally proceed.

There is also *severance of the tenants* in assise; when one, two, or more disseises appear upon the writ, and not the other. And *severance in debt*, where two executors are named plaintiffs, and the one refuses to prosecute. We also meet with *severance of summons*, *severance in attainds*, &c.

An estate in joint tenancy may be severed and destroyed by destroying any of its unities. 1. That of time, which respects only the original commencement of the joint estate, cannot indeed (being now past) be affected by any subsequent transaction. But, 2. The joint-tenant's estate may be destroyed, without any alienation, by merely disuniting their possession. 3. The jointure may be destroyed, by destroying the unity of title. And 4. By destroying the unity of interest. Blackst. Comm. book ii.

SEVERANCE of Corn. The cutting and carrying it from  
VOL. XXXII.

off the ground; and sometimes the setting out the tythes from the rest of the corn, is called severance.

SEVERIA, or SIEWEIRZ, in *Geography*, a town of Austrian Poland, in Galicia, capital of a duchy sold by the duke of Teschen to the bishops of Cracow; 4 miles N.W. of Cracow.

SEVERIA, a town of European Turkey, in the Morea; 14 miles N.E. of Mistra.

SEVERIANS, SEVERIANI, in *Ecclesiastical History*. There were two sects of heretics thus called: the first, who are as old as the beginning of the third century, were an impure branch of the Gnostics; thus called from their chief, Severus.

The second, by some called Severites, were a sect of Monophysites, or Eutychians; their leader, Severus, was preferred to the see of Antioch in 513, where he did his utmost to set aside the council of Chalcedon.

SEVERIK, in *Geography*, a town of Asiatic Turkey, in the government of Diarbekir; 50 miles W. of Diarbekir.

SEVERIN, or SZÖRENY, a town of Walachia, on the Danube, founded by the emperor Severus; 12 miles E. of Orsova.

SEVERINUS, pope, in *Biography*, a Roman, was elected soon after the death of Honorius, in 638, but was not consecrated till May 640, when the papal see had been vacant nearly two years. This delay was owing to the refusal of the emperor to confirm the election till the clergy of Rome had promised that their bishop should sign the declaration of faith relative to the one will of Christ, drawn up by Sergius, the patriarch of Constantinople, and published by Heraclius. During the vacancy of the see, the Lateran palace was plundered of all its treasures by the exarch of Ravenna. At length the confirmation of the election of Severinus arrived, but he enjoyed his elevation only about two months, which afforded opportunity for no remarkable act, except that he refused to receive the declaration, and even published a decree condemning it.

SEVERINUS, MARCUS AURELIUS, a distinguished physician, was born at Tarsia, in Calabria, in the year 1580. His early inclination led him to the study of the law; but he subsequently abandoned that pursuit for the profession of medicine, and received the degree of doctor in the university of Naples. He became ultimately one of the most celebrated professors of that school, and taught anatomy and surgery with such reputation, as to attract a crowd of students to the university. His method of treating surgical subjects in his writings was highly commended by Bartholin. He was, however, a harsh practitioner, and censured the inertness of his contemporaries, for neglecting the cautery and the knife, as employed by the ancients, and himself carried the use of the actual cautery to a great extent. He died at Naples, on the 15th of July, 1656, at the age of seventy-six. He was a man of bold and original mind, but somewhat attached to paradox; and was the author of several publications, of which we have the following catalogue. "Historia Anatomica, Observatioque medica eviscerati hominis;" 1629. "De recondita abscessuum naturâ Libri octo;" 1630, which passed through many editions. "Viperæ Pythia, id est, de Viperæ natura, veneno, et medicina;" 1643. "Zootonica Democritea, id est, Anatomie generalis totius animantium opificii, Lib. v." 1645, containing the result of his dissection of a great many animals. "De efficaci Medicina, Libri iii." 1646. In this work he extols the advantages of fire and steel in the cure of diseases. "De Lapide fungifero, de Lapide fungimappa, Epitole duæ;"

1649. "Therapeuta Neapolitanus, five curandarum Februm et Morborum interiorum Methodus;" 1653. "Trimembris Chirurgia;" 1653. "Seilo-Phlebotome castigata, five de Venæ Salvatellæ usu et abusu censura;" 1654. "De Aqua Pericardii, cordis adipe, poris choledocis;" 1654. At the time of his death, Severini was preparing for publication some papers, which he meant to illustrate by engravings; they were published together, and entitled, "Antiperipatiæ, hoc est, adversus Aristoteles de respiratione piscium Diatriba." "Commentarius, in Theophrastum de piscibus in sicco viventibus." "Phoca anatomicè spectatus;" 1661. A sort of extract or abridgment of his writings on surgery was also published in 1664, with the title of "Synopsis Chirurgicæ Libri vi." See ELOY Dict. Hist.

SEVERN, in *Geography*, the second most important river in England, is supposed by some antiquaries to derive its name from the British word *fabrin*, sandy, or muddy; but others, with greater probability, consider it as a corruption of the Saxon term *saferne*, which signifies flowing. This river has its source from a large bog on the top of Plinlimmon-hill, in Montgomeryshire, North Wales, whence running down with a swift current, and being joined by many lesser torrents, it presently appears considerable; and passing by Llanydlos and Newtown, becomes navigable near Welsh-Pool, where the river Vernew joins it with a stream little inferior to its own. From thence proceeding gently to Shrewsbury, which it almost surrounds, it flows on through a rich vale, with many extensive windings, to Benthall Edge; by the way receiving into it the river Tern, which waters all the north of Shropshire. Here the Severn begins to be rapid, being pent up from thence, to Bridgenorth and Bewdley, by high woody banks and rocky cliffs, which afford a variety of beautiful prospects. Afterwards it again glides pleasantly on through the fertile plains of Worcestershire, visiting in its course the city of Worcester itself, near which it receives the waters of the Teme. At Tewkesbury it forms a junction with the Avon, and thereafter pursues its course to Gloucester, about fifty miles below which city the name of Severn is lost in that of the Bristol channel.

The Severn is a river of great importance, being navigated by vessels of large burthen for more than 160 miles from its mouth, without the assistance of any lock. Upwards of 100,000 tons of coal are annually shipped by the collieries about Madeley and Broseley, for the cities and towns situated on its banks, and thence conveyed into the adjacent counties. Great quantities of grain, pig and bar iron, iron manufactures, and earthen-ware, as also wool, hops, cider and provisions, are likewise sent to Bristol and other places, whence various kinds of goods are brought in return. This traffic is carried on with vessels of two sorts, the larger ones being called trows, and the lesser ones barges, or frigates. In May 1756, the number of these vessels navigating from Welsh-Pool, in Montgomeryshire, to Bristol, amounted to 376; but in consequence of the addition of the inland canals from the Trent, the Mersey, and the Thames, into the Stroud navigation, it may be fairly calculated that more than double that number are now employed. This river is peculiarly remarkable for its tide, which rolls in with a head of three or four feet high, foaming and roaring in its course, as if enraged by the opposition it meets with from the strong descending current of fresh water, which seems to contend with it for the superiority. They clash in such a manner as to dash the waters to a considerable height. This contest is called the *hygre*, or *eager*, as Rudder sup-

poses, from the French *eau-guerre*, i. e. water-war. Drayton, in his *Poly-Albion*, describes it in these words.

—"With whose tumultuous waves,  
Shut up in narrow bounds, the Hygre wildly raves,  
And 'frights the straggling flocks, the neighbouring shore  
to fly  
Afar, as from the main it comes with hideous cry,  
And on the angry front the hideous foam doth bring.  
The billows 'gainst the banks when fiercely it doth fling,  
Hurles up the slimy ooze, and makes the scaly brood  
Leap madding to the land, affrighted from the flood;  
O'erturus the toiling barge, whose steersman doth not  
launch,  
And thrulls the furrowing beake into her ireful paunch."

Rudder, in his "History of Gloucestershire," remarks that the bailiwick of the Severn is vested in the crown; that John Arnold obtained a lease of it in 1669 for 31 years, at 10*l.* a-year, and that the bailiff in 1779 was a Mr. Edward Baylis. From the rapid and boisterous character of this river, its waters are extremely muddy, a circumstance which renders it unfavourable as an abode for fish. It is, however, well furnished with salmon in some of the calmer spots, and is particularly famous for lampreys. For an account of the local circumstances of this river, and the scenery on its banks, see the articles MONTGOMERYSHIRE, SHROPSHIRE, WORCESTERSHIRE, and GLOUCESTERSHIRE, also WELSH-POOL, SHREWSBURY, and WORCESTER. Skrine's History of Rivers, 8vo. Atkyns's Ancient and present State of Gloucestershire, folio, 1768. Rudder's New History of Gloucestershire, fol. 1779. Fosbrooke's Abstracts of Records and Manuscripts respecting the County of Gloucester, 4to. 1807. Nash's History of Worcestershire, fol. 1782. Also Tours in Wales by Pennant, Bingley, Hutton, Skrine, Warner, and Wyndham.

SEVERN, a river of America, in Maryland, which runs into the Chesapeake, a little below Annapolis.—Also, a river of North America, which runs into Hudson's bay, with a settlement at its mouth, called "Severn House." N. lat. 56°. W. long. 88°.—Also, a river of North America, which runs from lake Simcoe to lake Huron.—Also, a river of Virginia, which runs into the Chesapeake bay, N. lat. 37° 23'. W. long. 76° 27'.

SEVERNDROOG, a sea-port town and fortress of Hindoostan, in Concan, taken by the English in 1756; 68 miles S. of Bombay. N. lat. 17° 55'. E. long. 72° 50'.

SEVERUS, LUCIUS-SEPTIMIUS, in *Biography*, a Roman emperor, was born at Leptis, in Africa, in the year 146 of the Christian era. His father, Septimius Geta, was of a Roman equestrian family, and his two paternal uncles were raised to the consular dignity. Severus was liberally educated, and made a proficiency in rhetorical studies. He came to Rome in the reign of Marcus Aurelius, by whom he was raised to the offices of advocate of the treasury, and senator. His youth was licentious; he however passed with credit through the offices of quæstor, tribune of the people, and prætor, in consequence of his active and regular performance of his public duties. After his quæstorship, he went into Africa, as lieutenant of the præconsul, where he shewed his sense of the dignity of office, and the importance of strict discipline, by causing an old acquaintance of ordinary rank to be scourged for greeting him familiarly, as he was walking, preceded by lictors. After he had completed the prætorian year, he was sent to Spain with the command of a legion. He passed some time in retirement at Athens, at the beginning of the reign of Commodus; after this, however, he was raised

raised to the highest honours, being successively appointed governor of the district of Lyons, consul, and commander of the legions posted on the banks of the Danube.

At the death of Commodus, Severus acquiesced in the elevation of Pertinax to the throne; but when, after the murder of that prince, the empire was purchased by Didius Julianus, he procured himself to be declared emperor by his Pannonian legions, in the year 193. Sensible that nothing was so essential to his success as celerity, after preparing his troops, he immediately commenced his march, which he performed on foot, at the head of a select body of guards, sharing with the meanest soldier all the hardships of his rapid advance. He entered Italy without meeting with any resistance, Julianus being incapable of any consistent and effective measures. On his approach to Rome, his competitor was deposed and put to death, and Severus received the decree of his election to the empire. His first act of power was to inflict a just punishment on those of the prætorian guards who were immediately concerned in the murder of Pertinax, which was the only blood that his elevation hitherto cost. Though he spared the lives of the rest of that mutinous and dissolute body, he determined to disband them, and with this view he summoned them on a plain near the city, ordering them to come without arms. He now reproached them for their want of discipline, stripped them of their ornaments, and ordered them, on pain of instant death, to depart to the distance of one hundred miles from the capital. Severus was not secure on his throne, having to contend with two formidable rivals, Pescennius Niger, governor of Syria, and Clodius Albinus, commander in Britain. Niger being the more powerful, Severus made the first attack upon him; and in the mean time, to secure himself against the attacks of Albinus, he flattered his vanity, conferring upon him the title of Cæsar; and in a letter conceived in terms of apparent respect and friendship, he requested him to partake with himself the toils of government, which age and infirmity rendered him unable to undergo without an associate. In this manner he disarmed the unsuspecting soldier. Severus now marched out to encounter Niger, whom he defeated in several battles, of which the last was at Illus, in Cilicia. Severus was now freed from further contest by the death of his rival, who was slain in his flight to the Euphrates, but he used his victory with great rigour; he banished and afterwards put to death the sons of Niger, severely fined all the towns which had taken his part, and executed all the senators who had been officers in his army. Taking Byzantium after a long siege, he dismantled and reduced it to the condition of a village, confiscating all the property of the inhabitants. He remained in Asia some time after the victory over Niger, and made an expedition into Mesopotamia, where he obliged the Parthians to raise the siege of Nisibis, and gained other advantages over the Barbarians on the frontiers.

Severus was now too great to think of sharing his power with a partner: he accordingly deprived Albinus of the prerogatives attaching to the title of Cæsar, while Albinus laid claim to the rank of Augustus. An open rupture ensued, and each prepared to decide the contest. They met at Lyons, each at the head of 150,000 men, equal in valour and discipline. Severus was the conqueror, and his rival destroyed himself. This event took place in 197. Severus being now undisputed master of the empire, indulged without restraint his disposition to cruelty. After putting to death the family of Albinus, and all the prisoners of rank taken in the battle, together with many citizens in the towns of Gaul, which had favoured his rival, he extended his severity to the Roman senate, which had displayed an

inclination towards the cause of Albinus. By way of insult to that body, he conferred divine honours on the tyrant Commodus, whose memory they had declared to be detestable and infamous; and when he returned to Rome, he made a reproachful and menacing speech to the assembled senate, followed by the execution, without trial, of twenty-nine, or, as another account says, of forty-one of the most distinguished members, whom of his own accord he pronounced guilty of favouring the enemy. Conscious of having thus made himself odious to the superior classes, he endeavoured, by all the means in his power, to ingratiate himself with the people at large by public exhibitions, and by exemptions from certain duties; and it has been affirmed that, notwithstanding his tyranny, peace and prosperity were generally prevalent throughout the empire during the reign of this emperor. Severus studiously cultivated the affection of the soldiery, by the augmentation of their pay, and by privileges and indulgences which he granted them, and which have been considered as materially tending to introduce that relaxation of military discipline which in the end put a period to the Roman empire.

He supplied the place of the prætorian guards, whom he had disbanded, by a more numerous body, selected from all the legions, and consisting, in great part, of the natives of barbarous nations; and he conferred unusual authority on their commander Plautianus. To his reign is chiefly attributed the introduction of those maxims of imperial prerogative which entirely put an end to all ideas of a republic, and placed the government upon the footing of an absolute and unlimited monarchy. The indolence of the capital did not suit the disposition of Severus. Learning that, while he was engaged with Albinus, the Parthians had made an irruption into Mesopotamia, and threatened Nisibis, he hastened into the East, and not only relieved that city, but took Seleucia and Ctesiphon. He then marched towards Armenia, the king of which country sued for peace, and obtained it. Some successful incursions into Arabia concluded his eastern expedition, from which he returned in the year 203, after an absence of five or six years. He celebrated his victories by many splendid spectacles; and in the same year he married his son Caracalla, whom he had some years before created Augustus, to the daughter of Plautianus; his second, Geta, had been elevated to the rank of Cæsar, and both these princes had received their honours at a very early age. This union, which seemed likely to exalt the favourite minister Plautianus to the summit of fortune, was the cause of his destruction, for Caracalla, who had acquired a great ascendancy over his father, scorned his bride, and hated her father, and procuring an accusation against him of having formed a conspiracy to take away the emperor's life, he caused him to be killed in the presence of Severus. His death drew after it that of many of his relations and adherents, and the cruelty of the emperor increased with his years. The reciprocal hatred between his two sons, and the ferocious character of the eldest, were sources of the utmost disquietude to him in the midst of his external prosperity. He in vain employed every argument to reconcile them, and at length he placed them on a perfect equality, by raising Geta, as well as his brother, to the rank of Augustus. It was chiefly with a view of removing these princes from the licentiousness of the capital, and keeping them under his own eye, that in the year 208 he undertook an expedition to the northern part of Britain, the uncivilized tribes of which had made incursions into the Roman provinces. He took his sons with him, and at the head of a powerful army proceeded beyond the walls of Adrian and Antoninus, and penetrated to the northern extremity of the

island. He was harassed by the natives, who did not dare to meet him in the field, and he suffered much from the severity of the climate. At length the Caledonians purchased peace by surrendering all the country south of the Clyde and Forth, which he secured by raising a rampart between these firths. The attempts against his life by his son Caracalla, joined to age and a declining state of health, so reduced him, that he died at York in the year 209, in the 66th year of his age. In his last moments he recommended concord to his sons, and his sons he recommended to the protection of the army. Gibbon speaks of Severus ending a glorious and successful reign, but other historians have doubted whether Severus ought to be reckoned among the good or the bad emperors; for while his perfidy towards his competitors, his cruelty to vanquished enemies, and the general severity of his administration, justify a very unfavourable view of his moral character, it is not denied that he possessed in a high degree the virtues of industry and vigour, the love of order, attention to correct abuses, strict and impartial administration of justice, and simple and frugal habits of life. He was a good judge of the characters of men, and the empire was in general well administered and prosperous during his reign.

He is supposed to have been favourable, in the early part of his reign, to Christians, but the rapid increase of their number seems to have alarmed him, and he is reckoned the author of the fifth persecution, which took place in the tenth year of his reign, and which lasted with more or less violence, according to Dodwell, two years, and according to Bagnage, six years and upwards. See Lardner's Works, vol. viii. cd. 1790. ch. 23.

SEVERUS, CORNELIUS, a Roman poet, who lived in the reign of Augustus, was author of a poem entitled "Ætina," which has sometimes been attributed to Virgil. He is reported by Quintilian to have given a relation in verse of the Sicilian war, and some lines of his on the death of Cicero are quoted by Seneca the orator. It is to him that Ovid is supposed to have addressed one of his Pontic elegies, in which he is termed "Vates magnorum maxime regum." An elegant edition of the remains of this writer, was published with notes at Amsterdam in 1703, by Le Clerc; and they are printed in Mattaire's "Corpus Poetarum."

SEVERUS, SANCTUS, a Christian rhetorician and poet, was a native of Aquitaine, and flourished in the fourth century. He wrote an eclogue, which is still extant, where, in a dialogue between a Pagan and a Christian, he treats of the mortality of cattle. It was first printed in the "Poemata Vetera" of Pithæus, and has been several times republished. Gronovius gave an edition of it, with a preface, under the title "Severi Sancti sive Endeleichii Rhetoris de mortibus Boum Carmen, ab Elia Vinetto et Petro Pethæo servatum, cum notis John Weitzii et Wolfgang. Lug. Bat. 1715." Another edition was published by D. Richtern, with a preface, in 1747.

SEVESE, in *Geography*, a town of Italy, in the Milanese; 8 miles N.N.W. of Milan.

SEVIAMALLY, a town of Hindoostan, in the Carnatic; 19 miles W. of Trichinopoly.

SEVIER, a county of Tennessee, Hamilton district, containing 3419 inhabitants, of whom 162 are slaves.

SEVIÉRVILLE, a post-town and capital of the above county; 555 miles from Washington.

SEVIGNAC, a town of France, in the department of the Lower Pyrenées; 9 miles N. of Morlaas.

SEVIGNE, MARIE RABUTIN, *Marquise de*, in *Biography*, a distinguished lady, was born in 1626. Her father, baron of Chantal and Bourbilly, died while she was

very young, leaving her heirs of the house of Buffi Rabutin. Her rank, and the graces of her person and conversation, procured her many admirers, and in 1644 she married the marquis de Sevigné, who in 1651 was killed in a duel. She from this time devoted herself to her children, and to the cultivation of her own mind. She had an extraordinary affection for her daughter, who, in 1669, married the count de Grignan, and accompanied him to his government of Provence, and this separation gave rise to the greater part of the letters which have gained her so high a reputation, though she had many other correspondents. Many of M. de Sevigné's letters are of a domestic nature, but others are enlivened with court anecdotes, remarks on men and books, and topics of the period in which they were written, which render them very amusing; and in point of style, they are models of epistolary writing, which, perhaps, have never been surpassed. In her letters to her daughter, the reader sometimes is hurt with the excess of flattery on her talents and beauty, which latter quality appears to have been a principal source of her maternal tenderness, and the preservation of it the great object of her anxiety. This lady died in 1696, at the age of 70. Though endowed with much penetration, and, to a certain degree, with a cultivated understanding, she did not rise much above the level of her age and sex in taste and principles. She was attached to rank and splendour, loved admiration, and was apt to be taken with frivolous accomplishments in preference to solid worth. She had a deep sense of religion, but wished to conciliate it with the polite world, the manners and maxims of which, according to the rigid system of the Catholics, were entirely at variance with it. She has been censured for want of taste in her insensibility to the poetical merit of Racine, but this has been imputed to her prepossessions in favour of Corneille. The best editions of her letters are that in 8 vols. 1775; and that in 10 vols. 1801.

SEVIGNY, in *Geography*, a town of France, in the department of the Ardennes; 12 miles N.W. of Rethel.

SEVIL, in the *Manege*. The sevil of the branches of a bridle is a nail turned round like a ring, with a large head, made fast in the lower part of the branch, called *gargouille*. See BANQUET.

SEUIL, in *Geography*, a town of France, in the department of the Ardennes, on the Aisne; 12 miles S.E. of Rethel.

SEVILLE, a province of Spain, commonly called the kingdom of Seville, is now exclusively, but improperly, denominated Andalusia, and occupies the western part of ancient Bætica. Its figure is irregular, 58 leagues long from E. to W., and 27 broad from N. to S.; a point of it bending towards the Straits of Gibraltar, 14 leagues from N. to S. and 9 from E. to W. It is bounded to the E. by Cordova; to the E. and S.E. by Grenada; to the S. by the Atlantic and the Straits of Gibraltar; to the W. by the kingdom of Algarva, &c.; and to the N. by Eltramadura. There are two sea-ports in this province, the one in the Mediterranean at Algeziras, the other on the Atlantic at Cadiz: the latter is spacious and beautiful, the best known, and the most frequented in Spain; its bay is eight leagues round. The principal towns of the kingdom of Seville are its own capital, Seville, an archiepiscopal see; Cadiz, an episcopal see, fortrefs, and sea-port; Santa-Maria, a sea-port; Xeres, Ecija, and Offuna, inland towns. Its rivers are, the Saltes, Guadiana, Tinto, Odiel, Chanca, Verde, Barbate, Guadalette, Guadalquivir, Xenil, Guadianar, Guadaya, Las Feguas, Camdon, and San-Pedro.

## SEVILLE.

SEVILLE, in Spanish *Sevilla*, and in Latin *Hispalis*, the capital of the above kingdom, is a large handsome city, one of the first in Spain, and so ancient, that it is mentioned by Strabo, Pomponius Mela, Pliny, and Ptolemy, as being ancient even in their time. Fable ascribes its origin to Hercules, Bacchus, to the Hebrews, to the Chaldeans, and to the Phœnicians; but its real founder is unknown. From the Romans it obtained the privilege of a Roman colony, and it was called "Julia Romula," or Little Rome. This town has often changed its sovereign and its form of government. It was formerly subject to the Gothic kings, who made it the place of their residence; and in 582 it took part in the rebellion of Ermenegild, son of king Leudivigild. In 711, it opened its gates to the Moors; and in 1027 it supported the rebellion of the Moor, who was its governor, in favour of the king of Cordova, whom it proclaimed king of Seville. Restored to the empire of the sovereigns of Cordova, it again raised the standard of rebellion in 1144, and chose itself a king, whose descendants united Cordova to their new dominions. Aben-hut, the last of those kings, being assassinated at Almeria, and Ferdinand II., king of Castile and Leon, having seized upon Cordova and Jaen in 1236, it threw off all authority, formed itself into a republic, and was governed by its own laws. In its turn, however, it experienced the power of a conqueror. Ferdinand II. assembled his forces before Seville in 1247, and compelled it, after a year's resistance, to surrender 23d of Nov. 1248. From the period of this memorable siege Seville has always made a part of the dominions of the kings of Castile.

Seville is situated on a beautiful and extensive plain, on the banks of the Guadalquivir. Its shape is circular, and its circumference, as it was left by the Romans, is surrounded by a wall more than a league in circuit, flanked by 176 towers: the number of gates is 12, that of Triana being of Doric architecture, and ornamented with columns and statues. Over one of the gates is the following inscription:

"Condidit Alcides, renovavit Julius Urbem,  
Restituit Christo Fernandus Tertius, Heros."

The town is badly planned, the streets being narrow, crooked, and ill-paved: the houses, however, are tolerably well built, and, including those of the suburbs, amount to 11,820 in number. The number of inhabitants is stated by Mr. Townsend at 80,268, contained in 30 parishes, 84 convents, and 24 hospitals. Laborde estimates the present population, since the decline of its commerce, at 96,000. Many of the houses have large courts, surrounded by galleries or columns, with fountains in the middle. In summer the families live in the galleries, or courts, where they spread tents. In Seville there are many squares, the best of which are La Lonja, or the Exchange; the Hotel de Ville; the Arsenal, at the entrance of the harbour, with the Custom-house and the Gold-house, in which the gold and silver brought from the Indies are deposited: here are also several fine suburbs, and a handsome promenade, called Alameda, having three walks planted with trees, and ornamented with seats and fountains. This city is the see of an archbishop; and of the public ecclesiastical edifices, the first that demands attention is the cathedral, chiefly admired for its tower, constructed by Guever the Moor; originally, *viz.* A.D. 1568, 250 feet high, and afterwards raised 100 feet. It is so easy of ascent, and at the same time so spacious, that two horsemen may ride up abreast; and on the top is the Giralda, or brazen image, which, with

its palm-branch, weighs near  $1\frac{1}{2}$  ton, and yet turns with the slightest variation of the wind.

The dimensions of the cathedral are 420 feet, by 263; and the height is 126 feet. It was built A.D. 1401. It receives light by fourcore windows with painted glass, the work of Arnao of Flanders, each of which cost 1000 ducats.

The treasures of this church are inestimable: one altar is wholly silver, with all its ornaments, as are the images, large as life, of S. Isidore and S. Leander, and a custodia or tabernacle for the host more than four yards high, adorned with forty-eight columns; yet these are trifling in value, when compared with the gold and precious stones deposited by the piety and zeal of Catholics, during the period in which all the wealth of a newly-discovered world flowed into this city. The profusion of gold, of silver, and of gems, would be more striking, were not the attention occupied and lost in admiration of innumerable pictures, the works of those Spanish masters who flourished immediately after the revival of the art in Seville. Every chapel preserves some monuments of their superior skill. Of these, the most conspicuous are of Luis de Vargas, and of Fr. Zurbaran, but chiefly of Murillo. By the last is a Nativity in the chapel of the Conception, and, near the baptismal font, S. Anthony of Padua, with the Baptism of Christ. In the principal sacristy, are his much admired pictures of S. Isidore with his brother S. Leander; and in another sacristy his Holy Family, and an Ecce Homo by Morales. The chapter-house is wholly devoted to Murillo, and the chapel of S. Peter is given up to Zurbaran. The works of Luis de Vargas are dispersed in various places; but his famous picture called de la Gamba, is in a chapel near the gate of S. Christopher, and merits particular attention.

To the cathedral belongs a library of 20,000 volumes, collected by Hernando, son to Christobal Colon, the first discoverer of America, a man of taste, and much admired in his day for learning. It is to be lamented, that modern publications have not been added to complete what was so well begun by him.

The construction of the organ is peculiar; it contains 5300 pipes, with 110 stops, being, as it is said, 50 more than those of the famous one at Haerlem, yet, so ample are the bellows, that when stretched they supply the full organ fifteen minutes. The mode of filling them with air is singular; for instead of working with his hands, a man walks backwards and forwards along an inclined plane of about fifteen feet in length, which is balanced in the middle on its axis; under each end is a pair of bellows of about six feet by three and a half. These communicate with five other pair united by a bar; and the latter are so contrived, that when they are in danger of being overstrained, a valve is lifted up, and gives them relief. Passing ten times along the inclined plane fills all these vessels.

In the cathedral are eighty-two altars, at which are said daily five hundred masses. The annual consumption is fifteen hundred arrobas of wine, eight hundred of oil, and of wax about one thousand.

The wealth belonging to this chapter may be estimated by the numbers that are supported by it.

The archbishop, with a revenue of three hundred thousand ducats; or, in sterling, nearly thirty-three thousand pounds a-year.

Eleven dignitaries, who wear the mitre on high festivals, amply, but not equally, provided for.

Forty canons, of forty thousand reals, or about four hundred pounds each *per annum*.

Twenty prebendaries, with an income of thirty thousand reals each.

Twenty-one minor canons, at twenty thousand reals each.

Beside these, they have twenty chanters, called Veinteros, with three assistants, called Sochantres, two beadles, one master of the ceremonies, with a deputy, three attendants to call the roll and mark the absentees, thirty-six boys for singing and for the service of the altar, with their rector, vice-rector, and music-masters; nineteen chaplains, four curates, four confessors, twenty-three musicians, and four supernumeraries; in all, two hundred and thirty-five.

Many of the convents are remarkable for the beauty of their architecture; but, in Seville, the eye covets only pictures, and amidst the profusion of these, it overlooks works, which in other situations would rivet the attention, and every where fixes on the pencil of Murillo. His most famous performances are in the Hospital de la Caridad, and, suited to the institution, express some acts of charity; such as the Miracle of the Loaves and Fishes; the smiting of the Rock in Horeb; the Pool of Bethesda; the Reception of the returning Prodigal; Abraham addressing the three Angels, and pressing them to enter his habitation; the Deliverance of Peter from the Prison; and Charity, in the person of Elizabeth, washing the wounds and curing the diseases of the poor. Beside these, in the same hospital, is the Annunciation of the blessed Virgin; and two little pictures, the one of the infant Jesus, the other of John.

The church of the Capuchins is richly furnished with his works; and although in these the composition is more simple than in the former, yet they may be considered as some of the best of his productions. Eleven of his pictures are to be seen in a chapel called de la Vera Cruz, belonging to the Franciscans. These do much credit to his pencil; and not inferior to them, are many preserved in other convents; such as, an Ecce Homo, and the blessed Virgin, with the infant Jesus, in the church of the Carmelites; the Flight into Egypt, in that of La Merced Calzada; a rich variety of subjects in S. Maria de la Blanca; and S. Augustin writing, with S. Thomas of Villanueva, stripping himself to clothe the poor, in the convent of the Augustin friars, near the gate of Carmona. In the opinion of Mr. Townsend, the most masterly of all his works is in the refectory of an hospital designed for the reception of superannuated priests. It represents an angel holding a basket to the infant Jesus, who, standing on his mother's lap, takes bread from it to feed three venerable priests. No representation ever approached nearer to real life, nor is it possible to see more expression, than glows upon that canvas. In the parochial church of Santa Cruz are two pictures in a superior style, a Stabat Mater Dolorosa, which excels in grace and softness; and the famous Descent from the Cross, of Pedro de Campana, which Murillo was accustomed daily to admire, and opposite to which, by his own directions, he was buried.

This great painter was born A.D. 1618, and died in 1682.

His name stands high in Europe; but to form an adequate idea of his excellence, every convent should be visited, where he deposited the monuments of his superior skill.

In exactness of imitation he was equalled; in claro oscuro, and in reflected lights, he was surpassed by Velazquez; but not one of all the Spanish artists went beyond him in tenderness and softness.

Of the convents, that which is upon the most extensive scale belongs to the Franciscans. It contains fifteen clois-

ters, many of which are elegant and spacious, with apartments for two hundred monks; but at present they have only one hundred and forty in their community. These, like all their order, are fed by charity, and are much favoured by the people. Their annual expenditure is more than four hundred thousand reals, or in sterling about four thousand pounds, amounting to twenty-eight pounds eleven shillings and five-pence for each. But then out of this must be deducted the expence of wine, oil, and wax, with the alms distributed daily to the poor, which altogether is considerable.

Among all the hospitals, Mr. Townsend was most pleased with that of La Sangre, designed for the reception of female patients. The front is elegant, and the sculpture is much to be admired, more especially the three figures of Faith, Hope, and Charity. The wards are spacious, and the whole is remarkable for neatness.

Our limits will not allow our introducing particular descriptions of other public buildings; such as the Torre del Oro, the Plaza de Toros, the Aqueduct with its four hundred and ten arches, and especially the Exchange. The latter, planned by Herrera (A.D. 1598), and worthy of its great architect, is a quadrangle of two hundred feet, with a corridor or spacious gallery round it, adorned with Ionic columns, and supported by an equal number of Doric.

The university was founded in the year 1502, and soon rose into consideration. The name of Arias Montanus, who lies buried at the convent of S. Jago, is alone sufficient to give celebrity to this seminary. His translation of the holy scriptures will be valued by the learned, as long as the scriptures themselves shall be the objects of veneration to mankind. The number of under-graduates here is about five hundred.

We meet at Seville with the favourite institutions of count Campomanes, his academy for the three noble arts of painting, sculpture, and architecture, and his economical society of the friends of their country. Both these have been attended with success, and have given assistance not only to the arts, but to agriculture, to manufactures, and to commerce. About two hundred pupils attend the former.

The alcazar, or royal palace, built by the Moors, is very spacious. The principal article of manufacture in Seville is snuff; and it furnishes also cigars to a very considerable amount. The silk manufacture was also formerly very flourishing in this place; so that in the year 1248 it employed 16,000 looms, and 130,000 persons; and such was then the population of the city, that the Moors who left it, when it was surrendered to the Christians, were 400,000, besides multitudes who died during a sixteen months' siege, and many who remained after their fellow-citizens were gone. But in consequence of the accumulation of taxes and other circumstances, the number of looms has been very much diminished; so that A.D. 1740, the looms for wide silks amounted to 462, and for other purposes to 1856.

The country round the city to a considerable distance lies so low, that it is frequently overflowed, and upon some occasions the water has been eight feet high, even in their habitations. The soil is rich, and being at the same time very deep, its fertility is inexhaustible. The produce is corn, leguminous plants, hemp, flax, lemons, oranges and liquorice. The quantity of this exported from Spain is said to be annually not less than four thousand quintals, or nearly two hundred tons, a considerable part of which

is supposed to be purchased by the porter-brewers in London.

In consequence of vapours and miasmata, occasioned by stagnant water, and by frequent floods, the inhabitants of Seville and its neighbourhood are subject to tertians, to putrid fevers, and to hysterical disorders. The predispotion to such diseases may be likewise sought for in the quantity of cucumbers and melons consumed by them all the year, in consequence of which they are likewise infested with worms, accompanied with epilepsies, especially in the more youthful subjects. Other diseases arise from heat, whenever they have the Solano wind, that is, whenever the wind blows from Africa, they become liable to pleurisies, and also a very pernicious irritability of nerves. N. lat.  $37^{\circ} 12'$ . W. long.  $6^{\circ} 8'$ .

SEVILLA *del Oro*. See MACAS.

SEVILLE *Plantation*, a place on the N. coast of Jamaica, W. of Mammee bay, where are the ruins of an ancient town, called "Sevilla Nueva," founded by Esquivail on the spot where Columbus resided after his shipwreck in the year 1503.

SEVILLETA, a town of New Mexico; 100 miles S. of Santa Fé.

SEVIN, FRANCIS, in *Biography*, a man of letters, born in the diocese of Sens, was educated at Paris, where he pursued, with great ardour, the study of the learned languages, in company with the abbé Fourmont the elder. He became an associate of the Academy of Belles Lettres in Paris in 1714. He was sent in 1728, by the king's command, with the abbé Fourmont the younger, to Constantinople, in search of MSS., of which he brought back a great number, and was, in 1737, presented with the place of keeper of MSS. in the king's library. His letters, descriptive of this journey, were published in 1801, in one vol. 8vo. These contain several interesting details concerning Turkey, Egypt, &c. Sevin died in 1741. Several of his papers are published in the "Memoires de l'Acad. des Inscriptions."

SEVION, in *Geography*, a river of North Wales, which runs into the Clyde; 3 miles N.W. of St. Afaph.

SEVIR, among the Romans, an officer who, according to Pitiscus, commanded a whole wing of horse; though others make him only the commander of a troop, *turmis*, a division answering to our regiments.

SEVIRI were also magistrates in the colonies, so called, from their being six in number.

SEURAH, in *Geography*, a town of Hindoostan, in Bundelcund; 18 miles N. of Callinger.

SEVRE, or *Sevre Nantaise*, a river of France, which rises about eight miles W. from Parthenay, passes by Mortagne, Tiffauges, Clifson, &c. and runs into the Loire, opposite to Nantes.

SEVRE *Niortaise*, a river of France, which rises near St. Maixent, passes by Niort, Marance, &c. and runs into the sea; 7 miles W. of Marance.

SEVRES, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Versailles. The place contains 2643, and the canton 3485 inhabitants, on a territory of 50 kilometres, in eight communes.

SEVRES, *Two*, one of the nine departments of the western region of France, formerly Lower Poitou, between Vendée and Vienne, in N. lat.  $46^{\circ} 30'$ , containing  $6337\frac{1}{2}$  kilometres, or 305 square leagues, and 242,658 inhabitants. This department comprehends 4 districts, 30 cantons, and 363 communes. The districts or circles are, Thouars, including 43,543; Parthenay, 53,020; Niort, 84,923; and

Melle, 61,167 inhabitants. Its capital is Niort. According to Hassenfratz, the extent is 32 French leagues in length, and 12 in breadth: the number of circles is 6, and of cantons 50, and the population is 259,122. The contributions in the 11th year of the French era amounted to 2,556,115 francs; and the expences for administration, justice, and public instruction, to 233,694 francs 66 cents. The soil of this department, in general, is fertile, yielding grain, wine, fruits, and pastures. The S.W. district is marshy.

SEVRI, a river of Natolia, which runs into the Sakaria, near Sevribisar.

SEVRIHISAR, a town of Asiatic Turkey, in Natolia, at the conflux of the Sevri and Sakaria; 60 miles W. of Angora. N. lat.  $39^{\circ} 53'$ . E. long.  $32^{\circ} 2'$ .

SEURRE, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Beaune; 21 miles S. of Dijon. The place contains 2777, and the canton 11,546 inhabitants, on a territory of 280 kilometres, in 23 communes. N. lat.  $46^{\circ} 58'$ . E. long.  $5^{\circ} 12'$ .

SEVSK, a town of Russia, in the government of Orel, on the Sev; 56 miles S.W. of Orel. N. lat.  $52^{\circ} 15'$ . E. long.  $34^{\circ} 44'$ .

SEUTZACH, a town of Switzerland, in the canton of Zurich; 17 miles N.N.E. of Zurich.

SEVYNVEY, a river of South Wales, which runs into the Clethy, in Pembrokeshire.

SEW, in *Sea Language*, the situation of a ship when the water first leaves her resting on the ground, or blocks in a dock. Thus, if a ship runs a-ground on the tide of ebb, or by the reflux of the tide she rests on her blocks; and if it be required to know she has sewed, or how much she has sewed, the mark the water-line has made on her bottom when afloat is examined, and as much as is the difference above the surface of the water and this mark, so much she is said to have sewed.

SEW is also a term applied to a cow, signifying to go dry.

SEWAD, or SOWHAD, in *Geography*, a province of Candahar, situated on the W. side of the Indus, which separates it from Puckholi; 40 cosses long and 15 broad. This province, as well as Bijore, is very mountainous, and abounds with passes and strong situations; so that their inhabitants have not only held themselves generally independent of the Mogul emperors, but have occasionally made very furious inroads into their territories. The country of the Affaceni, or Affacani, answers to Sewad; Ashenagur being the ancient name of Sewad; or rather Sewad was one of the subdivisions of Ashenagur. At present Sewad includes the three provinces of Sewad *proper*, Bijore, and Bener.

SEWAD, the easternmost and largest of the four rivers that unite successively with the river Cabul, before it falls into the Indus; the other three being that which passes by the town of Bijore, the Peujakoreh river, separating Bijore on the W. from Sewad on the E., and the Chendoul river, which is a branch of the Bijore river.

SEWALICK, or SEWA-LUCK, a chain of mountains forming the northern boundary of Hindoostan, and separating the country of Lahore from Thibet.

SEWAN, or ALLIGUNGE, a town of Hindoostan, in Bahar; 32 miles N.N.W. of Chuprah. N. lat.  $26^{\circ} 11'$ . E. long.  $84^{\circ} 32'$ .

SEWARD, THOMAS, in *Biography*, an English divine of the church of England, was born in 1708. He became rector of Eyam, in Derbyshire, and prebendary of Litchfield, where he died in 1790. He was a man of taste and learning,

ing, and of considerable talents for poetry and polite literature. He published an edition of Beaumont and Fletcher's works, and was author of a treatise on the "Conformity between Popery and Paganism." Some of his poems are in Dodsley's collection.

SEWARD, ANNA, daughter of the preceding, a poetess of distinguished elegance, was born about the year 1745. Her infant mind was nourished by her father with the vivid and sublime imagery of Milton, and her early education amidst the wild and alpine scenery of the Peak, enhanced the enthusiasm of feeling to which she was naturally disposed. In her seventh year, her father being appointed canon residentiary of Litchfield, she removed with the family to that city, which thenceforth became her residence during the whole of her life. The fruit of her father's instructions appeared in some early efforts at poetical composition, which, however, met with discouragement from her mother; and Mr. Seward was afterwards induced to withdraw the countenance he had given to her literary pursuits; so that several years of her youth elapsed with only stolen and interrupted attempts to cultivate an art of which she had so strongly imbibed the rudiments. As she advanced in life, she of course followed more freely the bent of her genius, and in 1780 she published an "Elegy on Captain Cook," a performance of great merit, as well from the harmony of its versification, as the beautiful and appropriate imagery with which it abounds, and the force and delicacy of its sentiments. The contrast between the different mourners on this event, queen Oberea, and the wife of the great navigator, is peculiarly striking. In the following year she gave the world a "Monody on Major Andre." With this lamented young officer she was intimately acquainted: she accordingly wrote with peculiar pathos on the occasion, and expressed a glowing, and we scruple not to say, a just indignation against the actors in that tragedy: the laws of what are called civilized war do not and ought not to suppress the feelings of humanity. Miss Seward made herself known as a writer on many other topics: in 1790 she published "Llangollen Vale," with other poems; and in 1804 she gave the public "Memoirs of the Life of Dr. Darwin." This is a desultory performance, but it contains much entertaining matter, enriched with some judicious criticism on Dr. Darwin's poetical character. Miss Seward died in March 1809. A collection of her letters has been published since her decease, in six vols. 12mo. Athenæum. Monthly Mag.

SEWARD, WILLIAM, was the son of a brewer in London, and born in 1797. He received his education at the Charter House, which he completed at Oxford; this place he left without taking a degree. Having a good fortune, he devoted his life to literary ease, and antiquarian researches. He is known as an author by five volumes of "Anecdotes of distinguished Persons," extracted from curious books, to which he added a supplement, in two volumes, under the title of "Biographiana." Europ. Mag.

SEWARY, in *Geography*, a town of Hindoostan, in the circar of Surgooja; 22 miles E. of Surgooja.

SEWEE, a country of Asia, between Persia and Hindoostan, on the W. side of the Indus.

SEWEE Bay, or *Bull's Harbour*, a bay of the Atlantic, on the coast of South Carolina. N. lat. 32° 58'.

SEWEESTAN, a country of Hindoostan, between Sewee and the Indus, about 110 miles long and 50 broad.

SEWEL, among *Sportsmen*, denotes any thing that is fet or hung up, to keep a deer out of any place.

SEWEL-Coronde, a name given by the natives of Ceylon to a species of cinnamon, which, when chewed, is of a

mucilaginous nature, like the cassia: this dries well, and is very firm and hard, and has the appearance of a very fine cinnamon; but it has very little taste, and a disagreeable smell. The natives take advantage of the handsome appearance of this kind of cinnamon, and are very apt to mix it with the good kind, to the great detriment of the buyer. Phil. Trans. N° 409.

SEWER, formed from the French *escuyer, esquire, gentleman, or usher*, in the *Household*, an officer who comes in before the meat of a king, or nobleman, to place and range it on the table. Of these officers there are four in the king's household, and eight, called sewers of the great chamber.

SEWERS, in *Building*, are shores, conduits, or conveyances, for the suilage and filth of a house.

SEWERS, *Clerk of the*. See CLERK.

SEWERS, *Commission of*. See COMMISSION.

SEWIN, in *Ichthyology*. See GREY.

SEWL, in *Agriculture*, provincially a plough. It is sometimes written *fule*. See PLOUGH.

SEWNADY, in *Geography*, a town of Hindoostan, in the circar of Ruttunpour; 35 miles N. of Ruttunpour.

SEWNY, a town of Hindoostan, in Goondwanah; 60 miles N.N.E. of Nagpour.

SEX, SEXUS, something in the body, which distinguishes male from female. See GENERATION.

The number of persons, of the two sexes, are exceedingly well balanced; so that every man may have his wife, and every woman her husband.

Hermaphrodites have the apparent marks of both sexes.

It is expressly forbidden by the law of Moses, to disguise the sex.

SEXAGENARY, SEXAGENARIUS, something relating to the number sixty; more particularly a person arrived at the age of sixty years.

Some casuists dispense with sexagenarians for not fasting: the Papias law prohibits sexagenarii from marriage; because at that age the blood and humours are frozen.

SEXAGENARY *Arithmetic*. See SEXAGESIMAL.

SEXAGENARY *Tables*, are tables of proportional parts, shewing the product of two sexagenaries that are to be multiplied; or the quotient of two to be divided.

SEXAGESIMA, the second Sunday before Lent, or the next to Shrove Sunday; so called, as being about the sixtieth day before Easter.

Sexagesima is that which follows Septuagesima, and precedes Quinquagesima.

SEXAGESIMAL, or SEXAGENARY *Arithmetic*, a method of computation, proceeding by sixties.

Such is that used in the division of a degree into sixty minutes; of the minute, into sixty seconds; of the second, into sixty thirds, &c. See ARITHMETIC.

SEXAGESIMALS, or SEXAGESIMAL *Fractions*, are fractions, whose denominators proceed in a sexagecuple ratio; that is, a prime, or the first minute =  $\frac{1}{60}$ ; a second =  $\frac{1}{3600}$ ; a third =  $\frac{1}{216000}$ .

Anciently there were no other than sexagesimals used in astronomical operations, and they are still retained in many cases; though decimal arithmetic is now much used in astronomical calculations.

In these fractions, which some also call *astronomical fractions*, the denominator being always 60, or a multiple of it, is usually omitted, and the numerator only written down: thus, 4°, 59', 32", 50'''', 16''''', is to be read, 4 degrees, 59 minutes, 32 seconds of a degree, or 60th parts of a minute, 50 thirds, 16 fourths, &c.

SEXANGLE, in *Geometry*, a figure having six sides, and consequently six angles.

SEXDRAGA,

**SEXDRAGA**, in *Geography*, a town of Sweden, in West Gothland; 38 miles E. of Gotheborg.

**SEXES of Plants**, in *Vegetable Physiology*. See **FECUNDATION**, and **FRUCTIFICATION**.

**SEXT**, in *Geography*, a town of France, in the department of Mont Blanc; 2 miles S.E. of St. Maurice.

**SEXTA PARS**, Lat. a sixth vocal part in the motetti and madrigals of old masters.

**SEXTANS**, **SEXTANT**, a sixth part of certain things.

The Romans divided their *as*, which was a pound of brads, into twelve ounces: the ounce was called *uncia*, from *unum*; and two ounces *sextants*, as being the sixth part of a pound. See **AS**.

**SEXTANS** was also a measure which contained two ounces of liquor, or two cyathi. Hence,

“Sextantes, Caliste, duos infundi Falerni.”

**SEXTANS**, the *Sextant*, in *Astronomy*, a constellation of the southern hemisphere, made by Hevelius out of unformed stars. In Hevelius's catalogue it contains 11, but in the Britannic catalogue 41 stars. See **CONSTELLATION**.

**SEXTANT**, in *Mathematics*, denotes the sixth part of a circle, or an arc comprehending sixty degrees.

**SEXTANT** is more particularly used for an astronomical instrument, made like a quadrant; excepting that its limb only comprehends sixty degrees.

The use and application of the sextant is the same with that of the quadrant.

In the observatories of Greenwich and Pekin, there are very large and fine sextants.

**SEXTARIUS**, an ancient Roman measure, containing two cotylæ, or two heminae. See **COTYLA**.

**SEXTERY-Lands**, are lands given to a church, &c. for maintenance of the sexton.

**SEXTILE**, **SEXTILIS**, the position or aspect of two planets, when at sixty degrees distance; or at the distance of two signs from one another. It is marked thus (\*). See **ASPECT**.

**SEXTILIS**, in *Chronology*. See **AUGUST**.

**SEXTON**, a church-officer, thus called by corruption of the Latin *sacrista*, or Saxon *segerflanc*, which denotes the same. His office is to take care of the vessels, vestments, &c. belonging to the church; and to attend the minister, churchwarden, &c. at church. He is appointed by the minister or others, and receives his salary according to the custom of each parish.

Sextons, as well as parish clerks, are regarded by the common law as persons who have freehold in their offices; and, therefore, though they may be punished, yet they cannot be deprived, by ecclesiastical censures.

The office of *sexton in the pope's chapel*, is appropriated to the order of the hermits of St. Augustine. He is generally a bishop, though sometimes the pope only gives a bishopric, *in partibus*, to him on whom he confers the post. He takes the title of *prefect of the pope's sacristy*, and has the keeping the vessels of gold and silver, the relics, &c.

When the pope says mass, the sexton always tastes the bread and wine first. If it be in private he says mass, his holiness, of two wafers, gives him one to eat; and, if in public, the cardinal, who assists the pope in quality of deacon, of three wafers, gives him two to eat. When the pope is desperately sick, he administers to him the sacrament of extreme unction, &c. and enters the conclave, in quality of first conclavist.

**SEXTON'S River**, in *Geography*, a river of America, in Vermont, which runs into the Connecticut, N. lat. 43°. W. long. 72° 25'.

VOL. XXXII.

**SEXTULA**, a word used by some pharmaceutic writers to express the sixth part of an ounce, that is, four scruples, or one drachm and one scruple.

**SEXTUPLA**, Ital. *Sextuple*, Fr. and Eng. in *Music*, implies a compound time of triplets mixed with binary time. Sextuple time is never properly used but in the faraband, consisting of six even crotchets, or quavers, expressed by  $\frac{2}{3}$  or  $\frac{3}{4}$ , where triplets are out of the question. All other indications of compound measure, or, as formerly called, jig time, are at present the following;  $\frac{3}{8}$ ,  $\frac{3}{16}$ ,  $\frac{3}{32}$ ,  $\frac{3}{64}$ ; all which measures consist of triplets.

Old authors mention five different species of sextuple time: as,

**SEXTUPLE of the Semibreve**, by the French called triple of 6 for 1, as being denoted by those two numbers  $\frac{6}{1}$ ; or because here are required six semibreves to a measure, in lieu of one, *viz.* three rising, and three falling.

**SEXTUPLE of the Minim**, called by the French triple of 6 for 2, as being denoted by  $\frac{6}{2}$ ; which shew, that six minims are here required to a measure, instead of two.

**SEXTUPLE of the Crotchet**, called by the French triple of 6 for 4, because denoted by  $\frac{6}{4}$ , or  $\frac{3}{2}$ , which shew, that there must be six crotchets to a measure, in lieu of four.

**SEXTUPLE of the Chroma**, by the French called triple of 6 for 8, as being denoted by  $\frac{6}{8}$ ; which shew, that six quavers here make the measure, or semibreve, instead of eight.

**SEXTUPLE of the Semichroma**, or triple of 6 for 16, so called, because denoted by  $\frac{6}{16}$ ; which shew, that six quavers are here required to a measure, instead of sixteen.

**SEXTUS**, **SIXTH**, in the *Canon Law*, denotes a collection of decretals, made by pope Boniface VIII. usually thus called from the title, which is “*Liber Sextus*;” as if it were a sixth book added to the five books of decretals, collected by Gregory IX.

The *Sextus* is a collection of papal constitutions, published after the collections of Gregory IX. containing those of the same Gregory, Innocent IV., Alexander IV., Urban IV., Clement IV., Gregory X., Nicholas III., and Boniface VIII., by whose order the compilation was made. The persons employed in making of it were Will. de Mandegot, archbishop of Ambrun; and Berenger, bishop of Beziers; and Richard of Sienna. See **CANON LAW**.

**SEXTUS**, in *Biography*, an ancient philosopher of the stoical sect, was a native of Cheronea, and the nephew of Plutarch. He is celebrated as the preceptor of the emperors Lucius Verus and Marcus Aurelius.

**SEXTUS**, *Empiricus*, in *Medical History*, a Roman physician, of the *empiric* sect, who followed Heracides and others in the adoption of that system which Serapion and Plinius began. He is said to have been the pupil of Herodotus, the physician, and the preceptor of Saturninus. There are two works extant, with the name of Sextus attached to them; but Le Clerc believes, that they are not both the production of this physician, who only composed that which is entitled “*Sexti Placiti*;” and that the other work, which contains six books, treating of the doctrines of Pyrrhonius, and ten books relative to all the sciences, was the production of another Sextus, of Cheronea, who was of the Platonic school, a nephew of Plutarch, and preceptor of the emperor Marcus Aurelius. See **Le Clerc**, *Hist. de la Méd.* p. ii. chap. 8.

**SEXTUS Oculi**, in *Anatomy*, a name given by Fallopius to one of the muscles of the eye, called by Albinus, and others, the obliquus oculi inferior, and by some, the obliquus oculi brevis.

**SEXTUS Thoracis**, a name given by Fallopius, and others,

to a muscle, now generally known by the name of the *triangularis sterni*.

**SEXUAL SYSTEM**, in *Botany*, denotes that system, which is founded on a discovery, that there is in vegetables, as well as in animals, a distinction of the sexes; or that plants propagate themselves by means of male and female organs, either growing upon the same tree, or upon different trees of the same species. This system is suggested and confirmed by the analogy observable between the eggs of animals and the seeds of plants, both serving equally to the same end; *viz.* that of propagating a similar race; and by the remarks which have been made, that when the seed of the female plant is not impregnated with the prolific powder of the male, it bears no fruit; inasmuch that as often as the communication between the sexual parts of plants has been intercepted, which is the cause of their fecundity, they have always proved barren. The authors of this system, after exactly anatomizing all the parts of the plant, assign to each a name, founded on its use and analogy to the parts of an animal. Thus, as to the male organs, the filaments are the spermatic vessels, the antheræ the testicles, and the dust of the antheræ correspond to the sperm and feminal animalcules; and as to the female, the stigma is the external part of the female organ, which receives the dust; the style answers to the vagina; the germ to the ovary; and the pericarpium, or fecundated ovary, to the womb. See **VEGETATION**.

The sexual system was not wholly unknown to the ancients, though their knowledge of it was very imperfect. Accordingly we find in the account given by Herodotus (*lib. i.*) of the country about Babylon, where palm-trees abounded, that it was a custom with the natives, in their culture of these plants, to assist the operations of nature, by gathering the flowers of the male trees, and carrying them to the female. By this means they secured the ripening of the fruit; which might else, on account of unfavourable seasons, or the want of a proper intermixture of the trees of each sex, have been precarious, or at least not to have been expected in equal quantities. The ancients had also similar notions concerning the fig. Theophrastus (*Hist. Plant. lib. iii. cap. 9.*) observes, that the characteristic and universal difference among trees is that of their gender, whether male or female. And Aristotle (*De Plantis, lib. i. cap. 2.*) says, that we ought not to fancy, that the intermingling of sexes in plants is the same as among animals. However, there seems to have been a difference of opinion among the ancients as to the manner in which plants should be allowed to have a difference of sex. Some apprehended that the two sexes existed separately; and others thought that they were united in the same individual. Empedocles thought, that plants were androgynous or hermaphroditical, or that they were a composition of both sexes. Aristotle expresses his doubt upon this head. Empedocles (*vide Arist. de Generat. Anim. lib. i. c. 23.*) called plants oviparous; for the seed or egg, according to his account, is the fruit of the generative faculty, one part of which serves to form the plant, and the other to nourish the germ and root; and in animals of different sexes, we see that nature, when they would procreate, impels them to unite, and like plants to become one; that from this combination of two, there may spring up another animal.

As to the manner in which fruits were impregnated, the ancients were not ignorant that it was by means of the prolific dust contained in the flower of the male; and they remarked, that the fruits of trees never come to maturity till they had been cherished with that dust. Upon this subject Aristotle says (*De Plant. lib. i. cap. 6.*) that if one shakes the dust of a branch of the male palm-tree over the female,

her fruits will quickly ripen; and that when the wind sheds this dust of the male upon the female, her fruits ripen apace, just as if a branch of the male had been suspended over her. And Theophrastus (*Hist. Plant. lib. ii. cap. 9.*) observes, that they bring the male to the female palm, in order to make her produce fruit. The manner in which they proceed, says he, is this: when the male is in flower, they select a branch abounding with that downy dust which resides in the flower, and shake this over the fruit of the female. This operation prevents the fruit from becoming abortive, and brings it soon to perfect maturity. Pliny also informs us (*Nat. Hist. tom. i. lib. xiii. c. 7.*) that naturalists admit the distinction of sex, not only in trees, but in herbs, and in all plants. Yet this is no where more observable, he adds, than in palms, the females of which never propagate, but when they are fecundated by the dust of the male. He calls the female palms, deprived of male assistance, barren widows. He compares the conjunction of these plants to that of animals; and says, that to generate fruit, the female needs only the asperision of the dust or down of the flowers of the male.

Zaluzianski seems to have been the first among the moderns who clearly distinguished from one another the male, the female, and the hermaphroditical plants. About a hundred years after him, Sir Thomas Millington, and Dr. Grew, communicated to the Royal Society their observations on the impregnating dust of the stamina. Grew's *Anatomy of Plants*, published in 1682.

Camerarius, towards the end of the last century, observed, that upon plucking off the stamina of some male plants, the buds that ought to have produced fruit came not to maturity. Malpighi, Geoffroy, and Vaillant, have also carefully considered the fecundating dust; the latter of whom seems to have been the first eye-witness of this secret of nature, the admirable operation that passes in the flowers of plants, between the organs of different sexes. Many authors afterwards applied themselves to improve this system; the principal of whom were Morland, Logan, Van Royen, Bradley, Ludwig, Blair, Wolfius, &c. But Linnæus had the honour of applying this system to practice, by reducing all trees and plants to particular classes, distinguished by the number of their stamina, or male organs. See Dutens' *Inquiry into the Origin of the Discoveries attributed to the Moderns*, 1769, chap. vii. *Phil. Transf. vol. xlvii. art. 25.*

The sexual hypothesis, on its first appearance, was received with all that caution which becomes an enlightened age; and nature was traced experimentally through all her variations, before it was universally assented to. Tournefort refused to give it a place in his system; and Pontedera, though he had carefully examined it, treated it as chimerical. The learned Dr. Alston, professor of botany in the university of Edinburgh, violently opposed it; but the proofs which Linnæus has given amongst the aphorisms of his "*Fundamenta Botanica*," and farther illustrated in his "*Philosophia Botanica*," are so clear, that the mind does not hesitate a moment in pronouncing animal and vegetable conception to be the same; but with this difference, that in animals fruition is voluntary, but in vegetables necessary and mechanical. The impregnation of the female palm by the farina of the male, related by Mylius, in his letter to Dr. Watson (*Phil. Transf. vol. xlvii. art. 25.*) establishes the fact attested by the ancients concerning the palm-tree; and as the fructification in other vegetables, though it may differ in particular circumstances, has nevertheless a general conformity to that of the palm-tree, with respect to the parts supposed to be the organs of generation, which are discoverable either on the same or in a separate flower, we may, from this single experiment, deduce

an argument by analogy for the confirmation of the whole sexual hypothesis. Besides, a very striking proof of the analogy between plants and animals may be drawn from observations made in their infant states, at which early period they seem nourished and protected in a similar manner. Those who desire farther satisfaction, may see the several demonstrations collected, and methodically connected, in the "*Sponſalia Plantarum*" of J. Guſtavus Walhbor, published in the "*Amœnitates Academicæ*," at Leyden, in 1749. See **BOTANY, CLASSIFICATION, FRUCTIFICATION, PLANTS, and VEGETATION.**

**SEXUALISTÆ**, among *Botanical Authoꝛs*. See **BOTANY, FRUCTIFICATION, and SEXUAL System.**

**SEXUNX**, in *Pharmacy*, the weight of ſix ounces, or half a pound troy.

**SEYBO**, or **SEYVO**, in *Geography*, a ſettlement in the ſouthern part of Hiſpaniola; 70 miles N.E. of St. Domingo.

**SEYBORS DORF**, a town of Pruffia, in the province of Oberland; 6 miles S. of Liebfſtat.

**SEYCHELLES**, an iſland in the Indian ocean, N.E. of Madagaſcar; high and mountainous, and eſtimated at 72 miles in circumference. The ſoil appears to be rich and good, and the iſland is covered with trees, many of which would ſerve for masts and yards for ſhips, as they are large and ſtraight: among the trees are great quantities of roſe-wood, and cocconut trees. Wild goats, land-tortoiles, and Guinea-fowl, are found in plenty; and in the harbour abundance of good fiſh. The harbour is well ſheltered from the ſouth-eaſt wind. When the winds are from the north and north-weſt, it is rather an open road, but the ground ſeems to hold well. The tide riſes about ſix feet, and ſets about S.S.W. High water full and change, thirty minutes paſt five. S. lat. 4° 34'. E. long. 55° 35'.

**SEYDA**, or **SEDAU**, a town of Saxony; 10 miles E. of Wittemberg. N. lat. 51° 55'. E. long. 12° 59'.

**SEYDE**. See **SAIDE**.

**SEYDEWITZ**, a river of Saxony, which runs into the Elbe, near Pirna, in the marggravate of Meiſſen.

**SEYER**. See **PULO Seyer**.

**SEYER Oe**, an iſland of Denmark, in the Cattegat, about eight miles long, and hardly one broad; about five miles from the coaſt of Zealand. N. lat. 55° 53'. E. long. 11° 11'.

**SEYFFERS DORF**, a town of Sileſia, in the principality of Grotkau; 3 miles N.N.E. of Grotkau.

**SEYFORTES VOLT**, a town of Pruffia, in the province of Ermeland; 9 miles S. of Heiſſberg.

**SEYGAR**, in the *Materia Medica*, a name uſed by ſome authoꝛs for the nutmeg.

**SEYGERS W A L D**, in *Geography*, a town of Pruffia, in the province of Oberland; 4 miles N.E. of Salfeldt.

**SEY L O N E**, a town of Hindooſtan, in Oude, ſeated on a river which runs into the Goonty; 15 miles S.E. of Bareilly.

**SEYMAN**, an iſland in the Red ſea. N. lat. 15° 20'. E. long. 57° 30'.

**SEYMOUR, EDWARD**, in *Biography*, brother of lady Jane Seymour, wife of HENRY VIII. (ſee his article), and uncle to Edward VI., was created viſcount Beauchamp, earl of Hertford, and duke of Somerſet. On the acceſſion of his nephew to the throne he became his guardian, and protector of the kingdom. Not thinking that the vote of the executors of Henry VIII. was a ſufficient foundation for the high authority which he partly aſſumed by the influence which his relationship to the king gave him, he procured a patent from Edward, by which he overſet the meaning and

intent of the late king's will. In this patent he named himſelf protector, with full regal power, and appointed a council entirely of thoſe perſons whom he thought he could truſt. The protector became the warm friend of the reformation, and conſulted Cranmer on the beſt means of promoting the object he had at heart. He appointed a general viſitation to be made in all the dioceſes in England, the viſitors conſiſting of a certain number of the clergy and laity, and they had their different circuits aſſigned them. The chief purport of their inſtructions was, beſides correcting the immoralities and irregularities of the clergy, to aboliſh, but with a very lenient hand, ancient ſuperſtitions, and to bring diſcipline and worſhip ſomewhat nearer the practice of the reformed churches. Somerſet made war upon Scotland, and upon his return in Nov. 1547, he called a parliament, and being elated with the ſucceſſes which he obtained over the Scots, he procured from the young prince a patent, appointing him to ſit on the throne, upon a ſtool at the right hand of the king, and to enjoy the ſame honours and privileges that had uſually been poſſeſſed by any prince of the blood, or uncle of the kings of England. In this patent the king employed his diſpenſing power, by ſetting aſide the ſtatute of precedence enacted during the reign of his father. If, however, the protector gave offence by aſſuming too much ſtate, he deſerves high praiſe on account of the laws which were paſſed during this ſeſſion, by which the rigour of former ſtatutes was much mitigated, and ſome ſecurity given to thoſe principles of freedom which ſeem to make a part of the conſtitution. All laws were repealed which extended the crime of treaſon beyond the ſtatute of the twenty-fifth of Edward III.: all crimes enacted during the late reign extending the crime of felony; all the former laws againſt hereſy, together with the ſtatute of the ſix articles. None, in future, were to be accuſed for words, but within a month after they were ſpoken. "By theſe repeals," ſays Hume, "ſeveral of the moſt rigorous laws that were ever paſſed in England were annulled, and ſome dawn, both of civil and religious liberty, began to appear to the people."

About this time, moſt violent differences ſubſiſted between the protector and his brother, Thomas Seymour, admiral of England. The ambition of the latter was insatiable: he was beſides arrogant, aſſuming, and implacable; and though eſteemed of ſuperior capacity to the protector, he did not poſſeſs the ſame degree of confidence and regard of the people. By his flattery and addreſs, he had ſo far inſinuated himſelf into the favour of the queen-dowager, that ſhe married him almoſt immediately upon the demise of the king. The credit of this alliance ſupported the ambition of the admiral, and gave great offence to the ducheſs of Somerſet, who, uneaſy that the younger brother's wife ſhould have the precedence, employed all the credit ſhe had with her huſband, firſt to create, and then to widen the breach between the two brothers. Matters, at length, were carried ſo far, that the admiral was attainted of high treaſon, and executed by a warrant, which was ſigned by the hand of his brother, whoſe own diſgrace was at no great diſtance.

After the duke of Somerſet had obtained the patent, inveſting him, as it were, with full regal authority, he thought every one was in duty bound to yield to his ſentiments. Beſides his general hauteur, he gave great offence to the higher ranks of ſociety, by the attention with which he evidently courted the applauſe of the people at large. For the relief of the latter he had erected a court of requeſts in his own houſe, and he interpoſed with the judges in their behalf, a circumſtance that could not but be deemed illegal. Though the protector had thus courted the people, to the diſpleaſure and diſguſt of the nobles, whom Hume repreſents as "the

surest support of monarchical authority," the interest which he had formed with them was in no degree answerable to his expectations. The Catholic party, who retained influence with the lower ranks, as might be expected, were his declared enemies, and took advantage of every opportunity to decry his conduct. The attainder and execution of his brother bore an odious aspect: the introduction of foreign troops into the kingdom was represented in invidious colours: the great estate which he had suddenly acquired at the expence of the church, and of the crown, rendered him obnoxious; and the palace which he was building in the Strand served, by its magnificence, and still more by other circumstances attending it, to expose him to the censure of the public. The parish church of St. Mary, with three bishops' houses, were pulled down, in order to furnish ground and materials for this structure. Not content even with this, which, at that period, was regarded as great sacrilege, an attempt was made to demolish St. Margaret's church, Westminster, and to employ the stones for the same purpose, but the parishioners rose in a tumult, and chased away the protector's tradesmen. He then laid his hands on a chapel in St. Paul's church-yard, with a cloister and charnel-house belonging to it, and these edifices, together with the church called the St. John of Jerusalem, were made use of to raise his palace. All these imprudences were remarked by Somerset's enemies, who resolved, when an opportunity offered, to take advantage of them to his ruin. A conspiracy was soon formed against him, and he resigned his office, hoping that with this concession his foes might be satisfied, but he was mistaken, they determined to pursue him even to the scaffold. He was committed to the Tower, with some of his adherents, and articles of indictment were exhibited against him, of which the chief was his usurpation of the government, and his taking into his own hands the whole administration of affairs. The clause of his patent, which invested him with absolute power, unlimited by any law, was never objected to him, because, says Mr. Hume, "according to the sentiments of those times, that power was, in some degree, involved in the very idea of regal authority." Somerset prevailed upon to confess on his knees, before the council, all the articles laid to his charge, and he imputed these misdemeanors to his own rashness and indiscretion, not to any malignity of intention. He even subscribed a paper which contained a full confession of his guilt; he was accordingly fined two thousand pounds a-year in land, and deprived of all his offices, and here the matter for the present ended; the fine was remitted, and he recovered his liberty. After this, he was re-admitted into the council, and soon obtained a considerable portion of popularity, which rendered him an object of jealousy to the duke of Northumberland, who planned his destruction. Under pretence of an intended insurrection, he had him seized, with his friends, and committed to the Tower. He was now brought to trial before a jury of twenty-seven peers, some of whom were his avowed enemies, and was of course found guilty, and condemned to death. Care was taken to prepossess the young king against his uncle, and lest he should relent, no access was allowed to the duke of Somerset's friends, and the prince was, by a continued series of occupations and amusements, kept from reflection. The prisoner was executed on Tower-hill, much to the regret of the great body of people, who entertained the hopes of pardon to the last. A vast multitude of those friendly to him were the witnesses of his death. Many of them dipped their handkerchiefs in his blood, which they preserved as a precious relic; and some of them, when Northumberland, his great enemy and one of his jurors, met with a like doom, upbraided him with this act of his cruelty, and

displayed to him these symbols of his crime. "Somerset, indeed," says Hume, "though many actions of his life were exceptional, seems in general to have merited a better fate, and the faults which he committed were owing to weakness, not to any bad intention. His virtues were better calculated for private than for public life; and by his want of penetration and firmness, he was ill-fitted to extricate himself from those cabals and violences to which that age was so much addicted."

Somerset left three daughters, Anne, Margaret, and Jane, who were distinguished for their poetical talents. They composed Latin ditties on the death of Margaret de Valois, queen of France, which were translated into the French, Greek, and Italian languages, and printed in Paris in 1551. Anne, the eldest of these ladies, married first the earl of Warwick, the son of the duke of Northumberland, already mentioned, and afterwards sir Edward Hunton. The other two died single. Jane was maid of honour to queen Elizabeth.

SEYMOUR, ARABELLA, better known in history by the name of the lady Arabella, was daughter of Charles Stuart, earl of Lennox, youngest brother of Henry Danvers, husband to Mary queen of Scots. Her mother was daughter of sir William Cavendish of Chatsworth, in Derbyshire. Her affinity to the crown was the cause of her misfortunes. Several projects were formed for placing her on the English throne, so that she was kept under confinement in the reign of queen Elizabeth. At the beginning of that of James, a conspiracy, or rather a project of a conspiracy, was formed to raise her to the crown. She was first cousin to the king, being the daughter of a younger brother, which shews how rash the project was, supposing it to have been real; because James did not ascend the throne of England by the right of his father but that of his mother, consequently Arabella, though of the Stuart family, stood in a very remote degree of relation to the late queen Mary, had no claim to the crown of England, and the more so, as James had three children. The authors of this conspiracy were lords Grey, Cobham, sir Walter Raleigh, and others, who were tried, convicted, and condemned, but none were executed at the time, except a brother of lord Cobham, and two priests. The others were remanded to the Tower. (See RALEIGH). Arabella died in the year 1615, in prison, to which place she had been committed some time before, for having contracted marriage, without the knowledge of the crown, with William Seymour, grandson to the earl of Hertford. Hume. *Acta Regia*.

SEYMOUR'S Canal, in *Geography*, an inlet on the S.E. coast of Admiralty Island, extending from Point Hugh, about 28 miles N.N.W. of the entrance between Point Hugh and Point Gambier.

SEYMS, among *Farrriers*. See SEAMS.

SEYNE, in *Geography*, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Digne; 15 miles N. of Digne. The place contains 2557, and the canton 5227 inhabitants, on a territory of 307½ kilometres, in 8 communes.

SEYNEY, a town of Lithuania; 38 miles N.N.W. of Grodno.

SEYPOUR, a town of Hindoostan, in Oude; 40 miles N.E. of Fyzabad.

SEYSSÉL, CLAUDE DE, in *Biography*, an historical and political writer, who flourished in the beginning of the sixteenth century, was brought up to the law, which he practised with great applause at Turin. He obtained the places of master of requests and counsellor under Lewis XII. of France. He attended in the name of that prince at the

council

council of Lateran, and was promoted to the bishopric of Marseilles in 1510, and to the archbishopric of Turin in 1517. He died in 1520, leaving behind him a great number of works, on theological, juridical, and historical subjects. He also translated into the French language Eusebius's Ecclesiastical History, Thucydides, Appian, Diodorus, Xenophon, Justin, and Seneca. He is said to have been the first who alleged the Salic law as influencing the succession to the crown of France. His "Grand Monarchie de France," published in 1519, and translated by Sleidan into the Latin language, maintains that the French constitution is a mixed monarchy, and that the king is dependent on the parliament. In his "Histoire de Louis XII. Père du Peuple," he is the perpetual panegyrist of that prince, but gives some curious facts respecting the reign of Lewis XI., whose vices are exposed by way of contrast.

SEYSEL, in *Geography*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Belley, seated on the Rhone, which here becomes navigable, and divides it into two parts; 13 miles N. of Belley. The place contains 2260, and the canton 6032 inhabitants, on a territory of 122½ kilometres, in 5 communes.

SEZANE, or CEZANE, a town of France, in the department of the Po, on the Dora; 7 miles E. of Briançon.

SEZANNES, a town of France, in the department of the Marne, and chief place of a canton, in the district of Epernay; 45 miles W. of Vitry le Français. The place contains 4149, and the canton 12,203 inhabitants, on a territory of 300 kilometres, in 27 communes. N. lat. 48° 42'. E. long. 3° 48'.

SEZARNIK, a town of Hungary; 4 miles W. of Kapfdorf.

SEZENEVA, a town of Russia, in the government of Viatka; 16 miles N.N.E. of Glazov.

SEZULFE, a town of Portugal, in the province of Tras los Montes; 7 miles N.E. of Mirandela.

SEZZA, a town of the Campagna di Roma; 35 miles E.S.E. of Roma.—Also, a town of Naples, in Lavora, the see of a bishop, suffragan of Capua; 29 miles N.N.W. of Naples. N. lat. 41° 19'. E. long. 13° 34'.

SFACCIA, a town of European Turkey, in Albania; 8 miles N. of Dulcigno.

SFACHIA. See SPACHIA.

SFALASSA, a river of Naples, which runs into the sea; 4 miles E. of Cape Sciglio.

SFASACA, a town of Japan, on the S.W. coast of Nippon; 18 miles E. of Amanguchi.

SFAX, or *El Sfakuffe*, a town of Africa, in the kingdom of Tunis, surrounded with walls. The trade of the inhabitants in oil and cloth is considerable; 45 miles S.E. of Cairoan. N. lat. 34° 49'. E. long. 10° 56'.

SFORZA, GIACOMUZZO, in *Biography*, named also Attendolo, founder of the illustrious house of Sforza, was born in 1369 at Cotignola, in Romagna. He is said to have been originally a peasant, and, according to a traditional report, being one day at work, he was solicited to enlist for a soldier, when throwing his spade on a tree, he said he would enter if the spade did not fall down again, which proving to be the case, he immediately engaged in that military life which rendered him famous. He first served under general Alberic de Barbiano, and had for his comrade in arms the celebrated Braccio. These, in the early part of their career, were as intimate as brothers, but as they advanced in the profession, jealousy intervened, and they became at length such determined enemies, that when one engaged in the service of a prince or state, it was a sufficient motive for the other to engage on the opposite side. Sforza was soon distinguished

for his bravery, and for a disposition to seize by force whatever booty fell in his way. Braccio and he perfectly agreed in selling their services as dearly as possible, and in considering war as a trade which was to be kept up for their benefit. From the command of 100 men he rose to that of 7000: he obtained the office of gonfalonier to the holy see, and by pope John XXIII. he was created count Cotignola, an honour that was given by way of payment of a sum of money due to him. He commanded in the kingdom of Naples against Alphonso of Aragon, and was made constable of the kingdom. In marching to the relief of Aquila, he was drowned in the passage of the river Aterno or Pescara, in the year 1424. He is represented to have been robust in body, and when elevated to his highest rank, that he preferred the peasant's disregard of luxury, and frankness of manners.

SFORZA, FRANCESCO, first duke of Milan of that family, natural son of the preceding, was born in 1401. In 1421 he was viceroy to Louis, duke of Anjou, who had been adopted by queen Joan II. of Naples, and in 1424 he defeated the troops of Braccio; but his father, as we have seen, being drowned, he could make no advantage of his success. Although an illegitimate son, Joan conferred upon him all his father's estates, and he served successfully against the Aragonese commanders. He afterwards entered into the service of the duke of Milan, and defeated a fleet of the Venetians in the Po, in 1431. After the death of the queen, in 1435, he attached himself to her heir, René, duke of Anjou, and made himself master of several places in the Marche of Ancona. He even seized some of the pope's possessions, which brought on him an excommunication from Eugenius IV. whom he had formerly served. He had long wished to marry Bianca, the natural daughter of Philip-Maria Visconti, duke of Milan, and being in the Venetian service against that prince, he gained such advantages as induced Philip, who had often deceived him, to enter into a treaty in 1441, by which he made peace with the Venetians, and gave his daughter to Sforza, with Cremona and its territory for her portion.

The father and son-in-law did not long continue united, and Sforza commanded, as general, the troops of the pope, Venetians, and Florentines, in a war against Philip. He was, however, at length, induced to go over to the party of the duke of Milan, who, in 1447, died without legitimate issue. Sforza was now ambitious of succeeding him, and took a commission, as general of the troops of Milan, against the Venetians. But he soon made a treaty with the latter, and then led an allied army to the gates of Milan, to which he laid siege. The distress of the city occasioned a popular commotion, the leaders of which proposed the electing of Sforza for their duke. The majority concurred in the proposal, and in February 1450 he was received with great acclamations in that quality. Sforza remained in possession of the duchy, and in 1464 made himself master of Genoa, Lewis XI. of France having made over to him all the right of France to that city. Sforza died in 1466, and transmitted the sovereignty to his son. He had shown himself a brave and skilful commander; but with several traits of grandeur in his character, he was not a man of principle, and was ready to change sides as suited his interest. Mod. Univ. Hist.

SFORZA, CATHERINE, an heroine of the same family, the natural daughter of Galeazzo Sforza, duke of Milan, who was assassinated in 1476. She married Jerome Riario, lord of Forli and of Imola, which was her own dowry; but she was left a widow at the age of twenty-two, with several children. In 1500 Forli was besieged by the duke of Valentinois, son of pope Alexander VI. but she defended

the fortrefs with the greateft bravery, though the befiegers threatened to put her children to death, who were in their hands. At length the place was taken, and Catherine fent prifoner to Rome, but fhe foon recovered her liberty, and was married to John de Medicis, to whose family fhe rendered very eminent fervices.

**SFORZA, ISABELLA**, an ingenious lady of the fame family in the fixteenth century. Her letters were printed at Venice in 1549, by Hortenfio Lãudo.

**SFRONDATI, FRANCIS**, a fenator of Milan, and counfellor of ftate to the emperor Charles V. On the death of his wife he entered into orders, and was elevated to the cardinalship. He died in 1550, aged 56. A poem of his, on the "Rape of Helen," was printed at Venice in 1559. His fon Nicholas became pope by the name of Gregory XIV: there was another cardinal of this name and family, who wrote feveral works againft the liberties of the Gallican church. He died in 1696.

**SFUGGITO**, Ital. in *Mufic*, to fhun, avoid, go out at the common way: as *cadenza sfuggita*, a difappointed cadence. This happens when the bafe feems preparing for a full clofe; inftead of falling a 5th or rifing a 4th, it rifes only one tone or femitone, or falls a 3d; or in other words, when all the parts avoid their natural and expected conclufion.

**SFUMBERG**, in *Geography*, a town of Bohemia, in the circle of Chrudim; 5 miles S.S.E. of Chrudim.

**SGIGATA, SGZGATA**, or *Stora*, a town of Africa, in the country of Algiers, anciently called Rificada; fituated near the coast of the Mediterranean. A few cisterns are the only remains of its ancient fplendour; 30 miles W. of Bona. N. lat. 36° 48'. E. long. 6° 40'.

**SGIGATCHEE**, or *SHIGATCHEE* *Jeung*, a town of Thibet, fituated in a narrow valley, on a ridge of rock, fo as to command the road near the river Painom-tchieu; 130 miles W.S.W. of Laffa. N. lat. 29° 5'. E. long. 88° 52'.

**SGRAFFIT, SGRAFFIATA**, in *Painting*. See *SCRATCH-WORK*.

**SHAAB** at *Yudayn*, in *Geography*, a dry thelf in the Red fea, extending from N.E. by E., deriving its name from its fupposed refemblance to two arms wide open with their hands, fituated at the end of a great bay, far out to fea. There is a feure harbour on the fide towards the land.

**SHAAL STONE**, in *Mineralogy*. See *TABULAR SPAR*.

**SHAB**, in *Agriculture*, a difeafe of fheep. See *SCAB*.

**SHAB**, or *Sheb*, in *Geography*, a town of Africa, in the county of Nubia; 400 miles S.S.W. of Cairo. N. lat. 23° 35'. E. long. 30° 30'.

**SHABADPOUR**, a town of Hindooftan, in Oude; 50 miles W. of Kairabad.

**SHABALA**, a name of a wonderful boon-granting cow, often fpoken of in Hindoo romance; but more commonly under the name of *Surabbi*; which fee.

**SHABALEG**, in *Geography*, a mountain of Turkeftan; 70 miles N.N.E. of Toncat.

**SHABAMUSHWAN LAKE**, a lake of Canada; 210 miles N.N.W. of Quebec. N. lat. 49° 10'. W. long. 75°.

**SHABAT**, a town of the kingdom of Charafm; 95 miles S.S.E. of Urgheuz.

**SHABAYAGAN**, a river of Canada, which runs into lake Michigan. N. lat. 48° 30'. W. long. 86° 45'.

**SHABAZPOUR**, a town of Hindooftan, in Allahabad; 16 miles S.E. of Corah.

**SHABRAN**, a town of Perfia, in the province of Schirvan; 40 miles N.E. of Schamachie.

**SHABUR**, a town of Perfia, in the province of Irak; 6 miles S.W. of Cafbin.—Alfo, a town of Egypt, on the weft branch of the Nile, thought to be the ancient Andropolis; 50 miles N.N.W. of Cairo. N. lat. 30° 47'. E. long. 31°.

**SHACK**, in *Ancient Customs*, a liberty of winter-pafturage. In the counties of Norfolk and Suffolk, the lord of the manor has shack, *i. e.* a liberty of feeding his fheep at pleafure, in his tenants' lands, during the fix winter months.

In Norfolk, shack alfo extends to the common for hogs, in all men's grounds, from the end of harveft till feeding-time. Whence to go a shack, is to feed at large.

**SHACK**, in *Agriculture*, provincially to fhed as grain at harveft. See *HARVESTING Grain*.

**SHACK**, or *Shack-corn*, a provincial term applied to the wafte corn left in the fields at harveft: alfo the flock turned upon the stubble after harveft, and likewise to fuch grounds as lie open to common fields. Pigs are the flock ufually employed in gathering this, and in fome parts flocks of geefe and turkies. Where pigs are clovered through the fummer, they are finifhed with the shacks and the acorns; but fome farmers are fo improvident, as neither to feed their clovers in that advantageous way, nor even keep pigs enough to pick up the wafte corn, which is fometimes abfolutely fuffered to rot in the fields. Young pigs anfwer well in this ufe, as they thrive greatly, efpecially when bred upon the farm.

**SHACK-Fork**, provincially a wooden fork for shaking ftraw off the barn-floor, made of forked willow, &c.

**SHACKLEFORD**, in *Geography*, a poft-town of America, in Virginia; 143 miles W.S.W. of Wafington.

**SHACKLES**, in *Ship-Building*, the fmall ring-bolts driven through the ports, or fcuttles, and through which the lashings or an iron hook paffes when the ports are barred in. There are alfo shackles put upon billow-bolts, for confining feamen, &c. who have deferved corporal punifhment.

**SHACORA**, in *Geography*, a town of Egypt, on the coast of the Red fea; 65 miles S. of El Cofeir.

**SHAD, ALAUSA**, in *Ichthyology*, the name of a fea-fifh, called alfo the *mother of herrings*, and by fome authors *clupea* and *triffa*, by the ancients *trichis*, or *trichias*, and the *clupea alfa* of Linnæus. See *CLUPEA*.

It very much refembles the herring in its general form, but it is flatter and broader, and grows to a cubit long, and four inches broad. The head flices down confiderably from the back, which at the beginning is very convex, and rather fharp; the body from thence grows gradually lefs towards the tail; the under jaw is rather longer than the upper; the teeth very minute; the dorsal fin is placed very near the centre, is fmall, and the middle rays are the longeft; the pectoral and ventral fins are fmall; the tail very forked; the belly extremely fharp, and ftroingly ferrated; the back is of a dusky blue; above the gills begins a line of dark fspots, which mark the upper part of the back on each fide; the number of thefe fspots is different in different fifh, from four to ten.

It is very common in many feas, and in fome of our large rivers which lie near the fea. They run up thefe in great numbers, and are then very fat; they afterwards become lean, and then go down to the fea again. They ufually fwim in large fhools together.

In Great Britain the Severn affords the shad in higher perfection than any other river; where it firft appears in May, but in very warm feafons in April, and continues about

about two months. The shad at its first appearance, especially near Gloucester, is esteemed a very delicate fish, and sells dearer than salmon. The London fishmongers distinguish it from that of the Thames, by the French name of *alose*. Whether they spawn in the Severn or Wye is not determined, as their fry has not yet been ascertained. The old fish come from the sea in full roe. The fishermen erroneously imagine that the bleak, which appears in multitudes near Gloucester in July and August, are the fry of the shad. Many of these are taken in those months only, but none of the emaciated shads are ever caught in their return. The Thames shad does not frequent that river till the month of July, and is esteemed a very insipid coarse fish. About the same time, the *twait*, a variety of the shad, makes its appearance near Gloucester, and is taken in great numbers in the Severn, but held in as great disrepute as the shad of the Thames. The true shad weighs sometimes eight pounds, but their general size is from four to five. The *twait*, on the contrary, weighs from half a pound to two pounds, which it never exceeds. The *twait* differs from a small shad only in having one or more round black spots on the sides; if only one, it is always near the gill, but commonly there are three or four, placed one under the other. Pennant.

No shad is to be taken in the Thames or Medway, except from May 10 to June 30. 39 Geo. II. cap. 21.

SHADDOCK, in *Botany*. See CITRUS.

SHADE, in *Agriculture*, any sort of protection employed for preventing the heat, cold, and rain, from affecting and injuring any kind of stock, whether of the nature of building or plantation, of the woody kind, &c. See SCREEN-Plantation, and SHELTER.

SHADE, in *Gardening*, any thing that intervenes to obscure or protect plants from the rays of the sun. It is effected in various ways by the gardener; as by mats, covers, &c.

SHADE, provincially a shed for fuel, or house for sheltering live-stock, &c.; it also signifies to shed as grain, as used in some places.

SHADE Mountain, in *Geography*, a mountain of Pennsylvania, N.E. of Lewistown.

SHADENDORFF, a town of Austria; 4 miles N.E. of Brugg.

SHADING of Plants, in *Gardening*, the art of protecting plants of young and tender growths in feed-beds, &c. from the sun. It is a necessary work on many occasions, in warm, dry, sunny weather in spring and summer, &c. in pricking out various sorts of small young plants from feed-beds, into nursery-beds, pots, &c. as well as small cuttings, slips, above-ground off-sets, pipings, &c. as likewise occasionally in transplanting any kind of more advanced plants, flowers, &c. into beds, or pots, in a hot, dry season; and sometimes to feed-beds of particular sorts of small or curious seeds, in hot sunny days; also to plants in hot-beds, under frames and glasses, both of young and more advanced growths. It is the most commodiously and effectually performed by garden mats in a sort of awning over the beds, to plants in the full ground, or to those in pots placed close together, or sometimes to feed-beds, either in that way, or by being spread on the surface; in the latter method, being occasionally watered over the mats: or sometimes, in hot dry weather, by some loose straw litter strewn over feed-beds, which by screening the surface from the parching sun, and preserving the moisture in the earth, promotes a more quick, regular, and free germination in the seed; and when the plants are come up, the covering is soon drawn off lightly with a wooden or other rake. To plants under

glasses in frames, &c. the occasional shading is effected either by mats spread thinly over the glasses, or sometimes by a little loose, long litter, shaken lightly over them, just during the fierce heat of the sun. In all cases the shade should not be made too thick, so as to darken the plants too much.

Also in the business of occasional shading, it is in general only to be continued in the warmest time of sunny days, generally longer to plants, cuttings, &c. which have not struck root, than those that are in a growing state; and in common with all plants in the full ground, or others designed for placing in the open air, where occasional shading is necessary, it should be discontinued on evenings, mornings, and nights, that they may enjoy the benefit of the full fresh air at these times; as also the tender sorts, striking or advancing in growth under glasses, having occasional shading when the sun is powerful, in the warmer part of the day, should remain unshaded before and after that time, that they may receive the necessary beneficial influence of light and air in a proper degree. But in plants, cuttings, slips, &c. that have had occasional shading till they have struck good root, and begin to advance a little in a renewed growth, the shading should be mostly discontinued gradually, especially for those in beds, pots, &c. in the open ground, or others designed for transplantation, or for placing in pots, in the full air for the summer, according to their kinds: but in some small tender plants of slender growth, the occasional shading may probably be necessary in longer continuation, as till they acquire more strength; and to plants remaining all summer in hot-beds, or under frames and glasses, the continuance of occasional moderate shading in hot sunny days will be proper; but in most young plants, cuttings, &c. pricked out or planted as above, and designed for the full ground or open air, not continued under glasses, the having the benefit of occasional shade till well struck is all they require.

The sorts of plants which require this kind of management are very numerous; but it is constantly mentioned in their culture where necessary.

SHADMAN, in *Geography*, a town of Grand Bucharica; 36 miles N.N.E. of Termid.

SHADOW, SHADE, in *Optics*, a certain space deprived of light, or where the light is weakened by the interposition of some opaque body before the luminary.

The doctrine of shadows makes a considerable article in optics, astronomy, and geography; and is the general foundation of dialling.

As nothing is seen but by light, a mere shadow is invisible: when, therefore, we say, we see a shadow, we mean partly, that we see bodies placed in the shadow, and illuminated by light reflected from collateral bodies; and partly, that we see the confines of the light.

If the opaque body, that projects the shadow, be perpendicular to the horizon, and the plane it is projected on be horizontal, the shadow is called a *right* shadow. Such are the shadows of men, trees, buildings, mountains, &c. If the opaque body be placed parallel to the horizon, the shadow is called a *versed* shadow; as the arms of a man stretched out, &c.

SHADOWS from opaque Bodies, *Lacons of the Projection of.*

1. Every opaque body projects a shadow in the same direction with the rays of light; that is, towards the part opposite to the light. Hence, as either the luminary or the body changes place, the shadow likewise changes its place.

2. Every opaque body projects as many shadows, as there are luminaries to enlighten it.

3. As the light of the luminary is more intense, the shadow

dow is the deeper. Hence, the intensity of the shadow is measured by the degrees of light that space is deprived of. In reality, the shadow itself is not deeper, but it appears so, because the surrounding bodies are more intensely illuminated.

4. If a luminous sphere be equal to an opaque one, which it illumines, the shadow this latter projects will be a cylinder; and, of consequence, will be propagated still equal to itself, at whatever distance it extends; so that, if it be cut in any place, the plane of the section will be a circle equal to a great circle of the opaque sphere.

5. If the luminous sphere be greater than the opaque one, the shadow will be conical. If, therefore, the shadow be cut by a plane parallel to the base, the plane of the section will be a circle; and that so much the less as it is at a greater distance from the base.

6. If the luminous sphere be less than the opaque one, the shadow will be a truncated cone: consequently it grows still wider and wider; and therefore, if cut by a plane parallel to its base, that plane will be a circle so much the greater as it is farther from the base.

7. To find the length of the shadow, or the axis of the shady cone, projected by a less opaque sphere, illumined by a larger; the semidiameters of the two, as  $CG$  and  $IM$ , (*Plate XX. Optics, fig. 1.*) and the distances between their centres  $GM$ , being given:

Draw  $FM$  parallel to  $CH$ ; then will  $IM = CF$ ; and therefore  $FG$  will be the difference of the semidiameters  $GC$  and  $IM$ . Consequently, as  $FG$ , the difference of the semidiameters, is to  $GM$ , the distance of the centres; so is  $CF$ , or  $IM$ , the diameter of the opaque sphere, to  $MH$ , the distance of the vertex of the shady cone, from the centre of the opaque sphere. If then, the ratio of  $PM$  to  $MH$  be very small, so that  $MH$  and  $PH$  do not differ very considerably,  $HM$  may be taken for the axis of the shadowy cone: otherwise the part  $PM$  must be subtracted from it, to find which, seek the arc  $LK$ , which is the measure of the angle  $LMK$ , or  $MHI$ , and this angle is one of the angles of the right-angled triangle  $MHI$ , the sides of which,  $MI$  and  $MH$ , are known; for this, subtracted from a quadrant, leaves the arc  $IQ$ , which is the measure of the angle  $IMP$ . Since then, in the triangle  $MIP$ , which is rectangular at  $P$ , besides the angle  $IMP$ , we have the side  $IM$ ; the side  $MP$  is easily found by plain trigonometry.

*E. g.* If the semidiameter of the earth be  $MI = 1$ ; the semidiameter of the sun will be  $= 117$ ; and therefore  $GF = 111$ ; and of consequence  $MH = 217$ ; since then  $MP$  is found by calculation to bear a very small ratio to  $MH$ ; for the angle  $MIP = KML$ , may be taken equal to the apparent semidiameter of the sun, because of the sun's great distance, and its considerable magnitude, in proportion to the globe  $M$ ; and therefore,  $MP : MI :: \text{fine of } 16' : \text{radius, i. e.} :: 217 : 1$ , nearly; and as  $MH$  is about 217 times  $MI$ ,  $PM$  may be neglected, and  $PH$  may be taken to be 217 semidiameters of the earth. See *ECLIPSE of the Moon*.

Hence, as the ratio of the distance of the opaque body, from the luminous body  $GM$ , to the length of the shadow  $MH$ , is constant; if the distance be diminished, the length of the shadow must be diminished likewise. Consequently, the shadow continually decreases as the opaque body approaches the luminary.

8. To find the length of the shadow projected by an opaque body  $TS$  (*fig. 2.*); the altitude of the luminary, *e. gr.* of the sun above the horizon, *viz.* the angle  $SVT$ , and that of the body, being given. Since, in the rectangled

triangle  $STV$ , which is rectangular at  $T$ , we have given the angle  $V$ , and the side  $TS$ ; the length of the shadow  $TV$  is had by trigonometry.

Thus, suppose the altitude of the sun  $37^\circ 45'$ , and the altitude of a tower 178 feet;  $TV$  will be found 230 feet nearly.

9. The length of the shadow  $TV$ , and the height of the opaque body  $TS$ , being given; to find the altitude of the sun above the horizon.

Since, in the rectangled triangle  $STV$ , rectangular at  $T$ , the sides  $TV$  and  $TS$  are given; the angle  $V$  is found thus: as the length of the shadow  $TV$ , is to the altitude of the opaque body  $TS$ , so is the whole sine to the tangent of the sun's altitude above the horizon. Thus, if  $TS$  be 30 feet, and  $TV$  45,  $TVS$  will be found  $41^\circ 49'$ .

10. If the altitude of the luminary, *e. gr.* the sun above the horizon  $TVS$ , be  $45^\circ$ , the length of the shadow  $TV$  is equal to the height of the opaque body, the triangle in this case being isosceles.

11. The length of the shadows  $TZ$  and  $TV$  of the same opaque body  $TS$ , in different altitudes of the luminary, are as the co-tangents of these altitudes.

Hence, as the co-tangent of a greater angle is less than that of a less angle; as the luminary rises higher, the shadow decreases; whence it is, that the meridian shadows are longer in winter than in summer.

12. To measure the altitude of any object, *e. gr.* a tower  $AB$  (*fig. 3.*) by means of its shadow projected on an horizontal plane.

At the extremity of the shadow of the tower  $C$ , fix a stick, and measure the length of the shadow  $AC$ ; fix another stick in the ground of a known altitude  $DE$ , and measure the length of the shadow thereof  $EF$ . Then as  $EF$  is to  $AC$ , so is  $DE$  to  $AB$ . If, therefore,  $AC$  be 45 yards,  $ED$  5 yards, and  $EF$  7 yards;  $AB$  will be  $32\frac{1}{2}$  yards.

13. The right shadow is to the height of the opaque body, as the cosine of the height of the luminary to the sine.

14. The altitude of the luminary being the same in both cases, the opaque body  $AC$  (*fig. 4.*) will be to the versed shadow  $AD$ , as the right shadow  $EB$  to its opaque body  $DB$ . Hence, 1. The opaque body is to its versed shadow, as the cosine of the altitude of the luminary to its sine; consequently the versed shadow  $AD$  is to its opaque body  $AC$ , as the sine of the altitude of the luminary to its cosine.

2. If  $DB = AC$ ; then will  $DB$  be a mean proportional between  $EB$  and  $AD$ ; that is, the length of the opaque body is a mean proportional between its right shadow and versed shadow, under the same altitude of the luminary.

3. When the angle  $C$  is  $45^\circ$ , the sine and cosine are equal; and, therefore, the versed shadow is equal to the length of the opaque body.

15. A right line is to a versed sine of the same opaque body, under the same altitude of the luminary, in a duplicate ratio of the cosine to the sine of the altitude of the luminary.

Right and versed shadows are of considerable use in measuring: as by their means we can commodiously enough measure altitudes, both accessible and inaccessible, and that too when the body does not project any shadow. The right shadows we use, when the shadow does not exceed the altitude; and the versed shadows, when the shadow is greater than the altitude. On this footing is made an instrument called the *quadrat*, or *line of shadows*; by means of which the ratios of the right and versed shadow of any object, at any altitude, are determined. This instrument is usually

usually added on the face of the quadrat. Its description and use, see under QUADRAT, and ALTITUDE.

SHADOWS, *The Doctrine of, in Perspective*, is the theory and practice of representing shadows, as projected from a given point at a finite distance, such as a candle, or as projected from the sun, where the distance, though not infinite, is, for the sake of simplicity, considered as such, in order that the rays may be all parallel; or otherwise, for this purpose, the rays may be supposed as proceeding from all points of space in parallel lines.

A line of shade is the line deprived of light by an opaque point opposed to the luminary.

A plane of shade is an opaque or dark plane, occasioned by the privation of light from the interposition of a straight line opposed to the luminary; and hence it is evident, that every plane of shade will pass through the luminary.

To find the shadows upon the surfaces of bodies occasioned by the privation of the sun's rays.

Given the vanishing line of a plane, the vanishing point of the sun's rays, the vanishing point of the feat of a ray on the plane, the representation of a point in space, and the representation of the feat of the point in the plane whose vanishing line is given; to find the representation of the shadow upon the plane of the picture.

Join the vanishing point of the line to the vanishing point of lines perpendicular to the plane, whose vanishing line is given, and you will thus obtain the vanishing line of another plane, in which is the original of the feat of the point, and the original of the line in projection; and therefore the intersection of the vanishing line given of the plane on which the feat of the line required to be drawn and the vanishing line found is the vanishing point of the feat of the line. Therefore, draw a straight line through the feat of the point given in projection to the vanishing point found, and the line thus drawn will be the whole representation of the feat.

This proposition is evident, since the vanishing line of every plane perpendicular to the plane whose vanishing line is given, will pass through the vanishing point of lines perpendicular to that plane; and since the feat of the original line, on the original of the plane given, is formed by a plane passing through the original line perpendicular to the given plane intersecting therewith: therefore the vanishing line of this perpendicular plane will pass through the vanishing point of lines perpendicular to the original of the plane given; but when two points in a vanishing line are given, the whole of the vanishing line is given, being the straight line passing through these points.

A general knowledge of the shadows of lines upon planes in any position ought first to be acquired; but as the relation of lines and planes to the horizon is generally given, it will be necessary to find the relation of these lines and planes to one another; and here it will be proper to observe, that whatever be the number of planes, the vanishing point of the sun's rays will remain unchangeable, or in the same position in respect of the first vanishing line, and will be common to all the different planes; but every different plane will have its own vanishing point for the feat of the sun's rays in that plane, and that vanishing point will be in the vanishing line of that plane. As vertical and horizontal planes occur most frequently in practice, these will require particular attention.

Given the inclination of a plane to the plane of the picture, both being perpendicular to the original plane, and the feat and inclination of a straight line in the plane of the horizon; to determine the vanishing point of the feat of the line on the vertical plane, and the vanishing point of the line.

Let the scheme, N<sup>o</sup> 1. (*Plate I. Shadows, fig. 1.*) represent the vanishing plane, and N<sup>o</sup> 2. the plane of the picture.

In the vanishing plane, N<sup>o</sup> 1, let  $v1$  be the vanishing line,  $e$  the point of light or place of the eye,  $AB$  the intersection of the original vertical plane, inclined to the plane of the picture in the angle  $Ag1$ . Let  $AD$  be the feat of the line, as given in position, to the horizon: make the angle  $DAF$  equal to the inclination of the line to the plane of the horizon; draw  $DF$  perpendicular to  $AD$ , and  $DB$  perpendicular to  $AB$ ; produce  $DB$  to  $K$ ; make  $BK$  equal to  $DF$ , and join  $AK$ , which is the feat of the line on the vertical plane. Draw  $el$  parallel to  $AB$ , and draw  $lh$  perpendicular to  $v1$ : in  $v1$ , make  $lm$  equal to  $le$ , and make the angle  $lmh$  equal to  $BAK$ , and  $h$  will be the vanishing point of the feat of the line. Draw  $ev$  parallel to  $DA$ , and  $vi$  perpendicular to  $v1$ : make  $vn$ , in the vanishing line, equal to  $ve$ ; make the angle  $vni$  equal to the angle  $DAF$ , which the original line makes with the plane of the horizon. Draw  $e\odot$  perpendicular to  $v1$ , meeting  $v1$  in  $\odot$ .

In the plane of the picture N<sup>o</sup> 2, let  $VL$  be the vanishing line answering to  $v1$ , N<sup>o</sup> 1: in  $VL$  make choice of any convenient point,  $\odot$ , for the centre of the picture: make  $\odot L$  equal to  $o1$ , N<sup>o</sup> 1, and  $\odot V$  equal to  $ov$ , N<sup>o</sup> 1: draw  $LH$  and  $VI$  perpendicular to  $VL$ , then  $H$  is the vanishing point of the feat of the line, and  $I$  the vanishing point of the line itself.

The points  $H$  and  $I$  will be both on the same side of the vanishing line of the horizontal planes.

This problem is the same when the feat and altitude of a ray of the sun are given, and the inclination of a vertical plane to the plane of the picture; to find the vanishing point of a ray of light, and the vanishing point of the feat of the sun's rays.

When the sun is on the same side of the picture with the spectator, the vanishing point of the feat of the rays, and the vanishing point of the rays, will be below the vanishing line  $VL$ ; but when on the other side of the picture, the vanishing point of the rays and the vanishing point of their feat will be above  $VL$ .

The following problem unites that of finding the vanishing points of the feat of a line, and the vanishing point of the line itself, with the vanishing point of the feat of the sun's rays and the vanishing point of the rays, as relating to the plane given.

Given the inclination of a plane to the plane of the picture, both being perpendicular to the original plane, the feat and inclination of a straight line, and the feat and inclination of the sun's rays, both to the plane of the horizon; to determine the vanishing point of the feat of the sun's rays, the vanishing point of the feat of the line on the vertical plane, as also the vanishing point of the sun's rays and vanishing point of the line itself.

It is evident, that the vanishing point of the feat of the sun's rays, and the vanishing point of the feat of the line, are both in the vanishing line of the plane, which is a straight line perpendicular to the vanishing line of the horizon; since the original of the feat of a ray, and the original of the feat of the line, are both in the original plane: and if the line be parallel to the original plane, the vanishing point of the feat of the line will be in the intersection of the vanishing line of the vertical plane with that of the horizon.

Join  $VS$ , (*fig. 2.*) and let it meet  $AB$  in  $s$ ; draw  $bs$  and  $aS$ , cutting each other in  $e$ , and  $bc$  is the shadow of the line required.

For the vanishing point of the line that projects the shadow and the vanishing point of the sun's rays, are in the vanishing

vanishing line of the plane of shade; and because the plane of shade is supposed to cut the original plane, the intersection, which is the shadow, will be a line in the original plane, and therefore the vanishing point of the shadow will be in the vanishing line of the original plane; and as it has been shewn that it is also in the plane of shade, it will therefore be in the intersection of the plane of shade, and the vanishing line of the plane on which the shadow is thrown.

This problem is general for planes and lines in all situations, but in the following examples the centre and distance of the picture are supposed to be given, and the position of the picture is that of being perpendicular to the primary plane or first original plane: the objects themselves are solids, whose edges or planes are supposed to be perpendicular to the plane on which they stand. As oblique positions very seldom occur in practice, we shall suppose the vanishing line of the original plane, on which the object is placed, to be given.

To find the shadow of a prism placed on the primary plane.

Let  $AB$  (figs. 3, 4, and 5.) be the vanishing line of the plane of the base, and since the picture is supposed to be perpendicular to the primary plane, the vanishing line of the plane of shade, occasioned by the vertical lines which form the concurrence of the sides of the object, will be perpendicular to the vanishing line  $AB$ . Let  $Ss$ , therefore, be the vanishing line of a plane of shade, occasioned by any line of concurrence,  $S$  being the vanishing point of the sun's rays, and  $s$  the intersection of the vanishing line of the plane of shade, with that of the plane on which the shadow is to be thrown.

Let  $gd$ ,  $ba$ ,  $mn$ , be the edges of the solid; join  $bs$  and  $aS$ , cutting each other in  $e$ ; and  $bc$  is the shadow, occasioned by the edge or line of concurrence  $ba$ . Draw  $cB$  and  $dS$ , cutting each other in  $e$ ; or, if necessary, produce them to cut in  $e$ , and  $ce$  is the shadow, occasioned by the edge  $ad$ , parallel to the plane of the original plane; also draw  $eA$  and  $Sf$ , cutting each other in  $i$ ; or, if necessary, produce them to cut each other in  $i$ , then  $ei$  will be the shadow of the edge  $df$ . Lastly, draw  $is$ , which will complete the shadow of the prism, as required.

Fig. 3. shews the shadows of the object when the sun is before the picture; fig. 4. shews the shadow when the sun is behind the picture; and fig. 5. when the sun is in the plane of the picture.

To find the shadow of a building with a break. Let  $VL$  (fig. 6.) be the vanishing line of the horizon,  $V$  the vanishing point of the horizontal lines, represented by  $ac$  and  $bd$ , that form the end of the building, also of  $ef$ ,  $gh$ , which represent the horizontal lines forming the sides of the break. Let the sun be supposed to be in the plane of the picture, or its rays parallel thereto, and let the planes  $abcd$  and  $egbf$  be in shade, and the plane  $egbf$  will throw a shadow upon the plane  $ablk$ , and the plane  $abdc$  upon the horizon. As the sun's rays are parallel to the picture, they will have no vanishing point, but still the rule will hold in this case also. Through the vanishing point  $L$ , draw  $LM$  perpendicular to  $VL$ , then  $LM$  is the vanishing line of the plane  $ablk$ , on which the shadow is to be thrown; through  $V$  draw  $VM$  parallel to the sun's rays, or make the angle  $LVM$  equal to the angle which the sun's rays make with the plane of the horizon. Thus  $M$  is the vanishing point of the shadow of all lines vanishing in  $V$ , upon the plane  $ablk$ : therefore, to find the shadow of the line  $bg$ , join  $Mb$ , and produce it to  $m$ ; and draw  $gm$  parallel to  $MV$ , then  $m$  will be the shadow of the point  $g$ , and  $bm$  of  $bg$ . Draw  $mn$  parallel to  $ge$ , and  $mn$  will be the

shadow of  $ge$ : therefore  $bmnf$  will be the whole shadow of the plane  $bgef$ , upon the plane  $ablk$ .

To find the shadow of the end  $abcd$  upon the plane of the horizon: draw  $ao$  parallel to  $LV$ , and  $bo$  parallel to  $MV$ ; then  $ao$  is the shadow of the vertical line  $AB$ : join  $oV$ , and draw  $dp$  parallel to  $MV$ , and  $op$  is the shadow of  $bd$ : join  $pL$ , and draw  $rq$  parallel to  $MV$ , and  $pq$  will be the shadow of the line  $dr$ , not seen: join  $sq$ , or draw it parallel to  $LV$ , then  $aopqs$  will be the shadow of the building upon the plane of the horizon.

Many more examples of shadows might be given, but if the principles here shewn are understood, the artist will not be at a loss to find the shadow of any right-lined object whatever: for to find the shadow of an object constituted by planes, and consequently terminated by straight lines, is no more than to find the shadow of these lines. If a circle be given, the circumference may be divided by parallel lines into parts, and the shadows of the points of division may be found by finding the shadows of the intercepted lines, and drawing a curve round the extremities.

If it were required to find the shadows upon several planes, first find the shadow in the plane on which the object stands, and observe where the shadow meets the next plane; then having the vanishing line of this second plane, observe where the vanishing line of the plane of shade cuts the vanishing line of this second plane, then the point of intersection is the vanishing point of the shadow on the second plane.

The principles shewn under the article PROJECTION, will apply equally to the representation of objects in perspective, particularly where the planes which throw the shadow intersect the plane on which the shadow is to be thrown; for by continuing the line that throws the shadow, and the intersection of the plane to meet each other, you have the point where the shadow terminates; and therefore, if a point be given in the shadow, the direction of the shadow will be known. Thus in the last example, suppose the line  $ao$  obtained; and since the point  $o$  is the beginning of the shadow of the line  $bd$ , produce  $ac$  and  $bd$  to meet in  $V$ : join  $oV$ , and draw the ray of the sun  $dp$ , then  $op$  is the shadow of  $bd$ : produce  $dr$  and  $cs$  to meet in  $L$ , and join  $pl$ ; draw the ray  $rq$  from  $r$ , then  $pq$  is the shadow of  $dr$ , not seen.

To find the vanishing line of a pole upon several planes.

Let  $ABCDEFGHIK$ , (Plate II. *Shadows*, fig. 1.) be the outline of a building, with a lean-to or pent-house  $DENPQ$ :  $V$  is the vanishing point of all horizontal lines, in the gable  $ABLIK$  of the main house, and also of the gable  $DMQC$  of the pent-house;  $L'$  is the vanishing point of all the horizontal lines in the parallel fronts  $BFG L$  and  $DENM$ ; and as all vertical planes have vertical vanishing lines,  $VR$  is the vanishing line of the parallel gables  $ABLIK$  and  $CDMQ$ ;  $LU$  the vanishing line of the fronts  $BFG L$  and  $DENM$ ;  $ILGH$  is the representation of the roof of the main building, and  $QMN P$  that of the pent-house.

Produce  $LI$  to meet  $VR$ , its vanishing point, in  $S$ : draw  $SL'$ , which will be the vanishing line of the inclined plane  $ILGH$ , for  $S$  and  $L$  are the vanishing points of two lines in that plane: produce  $MQ$  to meet  $VR$  in  $T$ , and draw  $TL$ ; then  $TL$  is the vanishing line of the inclined plane  $MNPQ$  of the roof of the pent-house, because  $T$  and  $L$  are the vanishing points of two lines in that plane.

Let  $WX$  be a pole, reeling upon the end of the house in the same plane with the gable  $ABLIK$ ; and let  $\odot$  be the vanishing point of the sun's rays: produce the pole  $XW$  to meet  $VR$  in  $R$ , then  $R$  is the vanishing point of the pole, or of the line that throws the shadow: therefore by drawing  $\odot R$ ,  $\odot R$  will be the vanishing line of the plane of shade, which let cut  $VI$ , the vanishing line of the horizon, in  $Y$ ; and

L U, the vanishing line of the vertical planes B F G I and D E M N of the walls, in U; V R, the vanishing line of the gables, in R; S L, the vanishing line of the main roof, in Z; and T L', the vanishing line of the pent-house, in Z'. We are now prepared for drawing the shadow of the pole W X upon the horizontal plane and upon the building.

Produce A B to meet W X in X, then X will be the point where the pole rests upon the ground or horizontal plane: draw X Y, cutting D E in *a*; draw U *a*, cutting D M in *b*; draw *b* R, cutting M Q in *c*; draw *c* Z', cutting P Q in *d*; draw U *d*, cutting G I at I; and draw I Z, cutting the ridge I H at *f*; then X *a b c d e f* will be the whole shadow of the pole.

For, since the shadow first begins at the foot of the pole or line in the plane of the horizon, and since the intersection of the vanishing line of a plane on which the shadow is to be thrown, and the intersection of the vanishing line of the plane of shade, gives the vanishing line of the shadow upon that plane; now Y is the intersection of the vanishing line of the plane of shade with the vanishing line of the horizon; therefore Y is the vanishing point of the shadow of the line W X upon the plane of the horizon. The next plane on which the shadow is thrown is D E N M; now L U is the vanishing line of the plane D E N M, and U is the point where the vanishing line of the plane of shade cuts L' U; therefore U is the vanishing point of the shadow upon the plane D E N M. The next plane on which the shadow is projected is the plane C D M Q: now V R is the vanishing line of the plane C D M Q, and it intersects the vanishing line of the plane of shade in R; therefore R is the vanishing point of the shadow upon the plane C D M Q. The next surface on which the shadow is projected is the plane, M N P Q, of the roof of the pent-house: now Z' is the intersection of the vanishing line of the plane of shade with the vanishing line of the plane M N P Q; therefore Z' is the vanishing point of the shadow on the plane M N P Q. The next surface on which the shadow is projected is the plane B F G I of the wall; but U has already been shewn to be the vanishing point of the shadow. The plane of the roof is the last surface on which the shadow is projected: now S L is its vanishing line, and it meets the vanishing line of the plane of shade in Z, therefore Z is the vanishing point of the shadow upon the roof.

In carrying the shadow of a line across several planes, it will not be surprising if some little inaccuracy takes place from the obliquity of intersections: it might be a great chance, that when the part of the shadow *d* I, which falls upon the plane B F G I, is drawn from the vanishing point U, through the point *d*, that it will meet the pole at I, as it ought to do. To remedy this, begin with the shadow I *d*, and proceed in the reverse order, until it meets the line W X at X, which it must in principle, and will not be liable to vary much in practice.

The points which direct the shadows upon the several planes might also be found by the methods shewn in the article PROJECTION.

The following observations will be useful in the practice of shadows.

When a straight line that throws a shadow is parallel to the picture, it is then represented parallel to the original. In this case it has no vanishing point; or, in other words, the vanishing point of the line may be said to be at an infinite distance; and, therefore, instead of the vanishing point of the line being joined to the vanishing point of the sun's rays, draw a straight line from the vanishing point of the sun's rays parallel to the projection of the line which throws the shadow, which will be the vanishing line of the plane of

shade; and therefore the intersection of the vanishing line of the plane of shade with the vanishing line of the plane on which the shadow is to be thrown, will give the vanishing point of the shadow on that plane, after the same analogy as lines which are inclined to the picture. This case is similar to that of the sun's rays being parallel to the picture: for here also the vanishing point of the rays is at an infinite distance; but as the plane of shade will still have a vanishing line, this line will be found by drawing a straight line through the vanishing point of the line that throws the shadow parallel to the sun's rays, as already shewn in a former example.

*Shadows projected from a given Point; as by the Light of a Candle or Lamp.*—It is evident, if the representation of the luminous point be given, and its seat upon any plane, also the representation of any point in space, and its representation upon that plane, the shadow of the point will be found by drawing a straight line from the luminous point through the point in space, and by drawing another straight line from the seat of the luminous point through the seat of the point in space; and the intersection of the two lines thus drawn will represent the shadow of the point upon the plane. But when the relation of several planes represented in a picture, the representation of the light with its seat, and the representation of a point in space with its seat, are given, to project the shadow of the point on the other planes, other considerations become necessary.

For this purpose, let A B C D (*fig. 2.*) be the inside of a room, confining internally of the vertical planes, A H, E I, F K, G C, and of the horizontal planes A E F G B and D H I K C: also, let L be the luminous point, and M its seat in the plane A E F G B. In order to form an idea of the point L, in respect of the other planes, it is necessary to have the intersection of a line drawn through L, in a given position with one of the planes. Thus, if it is known that the straight line L *a*, parallel to the picture, cuts the plane of the wall B K, in the point *a*; the position of the point L to any of the other planes may be easily determined, as follows.

Through *a* draw *a b* parallel to the vanishing line N O, of the plane B K, cutting B G, the intersection of the planes B K and A G, in *b*; through *b* draw *b* M parallel to P Q, the vanishing line of the floor, cutting A E, the intersection of the planes A G and A H, in *c*; also F E, the intersection of the planes A G and E I, in *d*. Draw *c e* parallel to N O, the vanishing line of the plane A H; and *d f* parallel to R S, the vanishing line of the plane E I. Then, because the intersecting and vanishing lines of any plane are parallel to each other, and because a line drawn parallel to the intersecting line is parallel to the picture; therefore the representations of all the lines, *a b*, *b c*, or *b d*, *c e*, and *e f*, are all parallel to the picture, and in a plane passing through the luminous point L.

Given the representation of any straight line T U, and the points V and W, where the lines T V and U W, drawn parallel to the picture and to each other, meet the plane A G, whose vanishing line, P Q, is given, to find the vanishing point, X, of the line T U.

Draw W V, cutting P Q, the vanishing line of the plane A G, in Y; and draw Y X parallel to T V or U W, meeting the line U T, produced in X, the vanishing point required.

To make this appear, it is evident that the vanishing line of a plane passing through W and V, must also pass through Y; and likewise the vanishing line of a plane passing through U W, must be parallel to it: wherefore Y X is the vanishing line of the plane, which passes through U W.

## SHADOW.

Now let  $WY$  cut the plane  $AX$  in  $Z$ ; and in this example the vanishing line,  $YX$ , is parallel to the vanishing line of the plane  $EI$ : therefore the planes, represented by  $EI$  and  $XUWY$ , intersect each other in a line parallel to the picture; and, therefore, the representation of such an intersection is parallel to  $XY$ , or to  $RS$ , the vanishing line of the plane  $EI$ .

Given the vanishing lines,  $AB$ ,  $CD$ ,  $EF$ , (*fig. 3.*) of three planes,  $GHIK$ ,  $LMNO$ , and  $MNIQR$ , the common intersection,  $NO$ , of the planes  $GHIK$  and  $LMNO$ ; also the intersections,  $NI$  and  $MN$ , of the planes  $GHIK$  and  $LMNO$ , with the plane  $MNIQR$ ; the representation,  $ab$ , of a line in the plane  $LMNO$ ; the point of light,  $c$ ;  $cd$ , a line parallel to the picture; and  $d$ , the point where it intersects the plane  $MNIQR$ : to find the shadow of the line on the plane  $GHIK$ .

First, find the representation of a ray of light parallel to the picture, thus: draw  $de$  parallel to  $AB$ , cutting  $MN$  at  $e$ ; draw  $ef$  parallel to  $EF$ : then if  $ab$  be not parallel to  $ef$ , produce  $ba$  to  $f$ , and join  $fc$ , which is the ray required. Secondly, find the vanishing line of a plane of shade passing through the line  $ab$ , and the ray  $fc$ , thus: produce  $ab$  to meet  $CD$  in  $D$ , which is the vanishing point of  $ab$ ; through  $D$  draw  $DF$  parallel to  $fc$ , and  $DF$  will be the vanishing line of the plane required. And, lastly, find the shadow of  $AB$  upon the plane  $GHIK$ , thus: produce  $ON$  and  $ab$  to meet in  $g$ ; from  $F$ , through  $g$ , draw the line  $Fgi$ ; and from the point of light,  $c$ , draw  $cbi$  and  $cai$ ; then  $bi$  will be the shadow of the line, as required.

For  $de$  being parallel to  $AB$ , the vanishing line of the plane  $MNIQR$ ,  $de$  will be parallel to the picture; and since  $ef$  is drawn parallel to  $EF$ , the vanishing line of the plane  $LMNO$ ,  $ef$  will be parallel to the picture; and because  $ba$  meets  $ef$  in  $f$ ,  $fc$  is a ray of light parallel to the picture, meeting the line  $ab$ ; and because  $CD$  is the vanishing line of the plane  $LMNO$ , and  $ab$  is in the plane  $LMNO$ , therefore the vanishing point of  $ab$  is in  $CD$ , and consequently at  $D$ , where  $ab$  produced meets  $CD$ : and because  $D$  is the vanishing point of  $ab$ , the vanishing line of the plane of shade will pass through  $D$  parallel to  $fc$ : but  $F$  is the intersection of the vanishing line of the plane of shade, with the vanishing line  $EF$  of the plane  $GHIK$ , on which the shadow is projected, therefore  $F$  is the vanishing point of the shadow on the plane  $GHIK$ ; and because  $g$  is the intersection of  $ab$  with the plane  $GHIK$ , the shadow will commence at  $g$ , and consequently drawing  $Fgbi$  gives the direction of the shadow; and lastly, because  $c$  is the luminous point, the rays  $cbi$  and  $cai$  will terminate the shadow.

As  $D$  would be the vanishing point of all lines parallel to the original of  $ab$  in the plane represented by  $LMNO$ ; and as different representations could not meet the line  $ef$  in the same point, the ray  $cf$  will have different positions, and consequently  $DF$ , which is drawn parallel thereto; and as the point  $D$  is stationary, the point  $F$  will be variable.

Given the representation of three rectangular planes, forming a solid angle, the representation of a point of light or candle, and the feat of the light on one of the planes; to find the feat of the light on the other two planes.

Let the three planes be  $ABCD$ ,  $ABGF$ ,  $AFED$ , (*fig. 4.*) it is evident that every two adjoining planes have three edges parallel to each other, one common to both, which is their line of concurrence; these edges will therefore vanish in

a point or be parallel to each other, according as the original planes are oblique or parallel to the picture: let the original planes be obliquely situated; therefore produce the sides  $CD$ ,  $BA$ ,  $GF$ , of the two adjoining planes  $ABCD$ ,  $ABGF$ , and they will all meet in  $V$ , their vanishing point; also produce the sides  $DE$ ,  $AF$ ,  $BG$ , of the two adjoining planes  $DAFE$ ,  $FABG$ , and they will meet in  $W$ , their vanishing point; likewise produce the sides  $CB$ ,  $DA$ ,  $EF$ , and they will meet in  $X$ , their vanishing point.

Let  $L$  be a luminous point, and  $S$  its feat in the plane  $ABCD$ : draw  $SX$ , cutting  $AB$  in  $a$ ; draw  $aW$ , and draw  $LX$ , cutting  $aW$  in  $S'$ , then  $S'$  is the feat of the luminous point in the plane  $ABGF$ : draw  $SV$ , cutting  $AD$  in  $b$ ; draw  $bW$ , and  $LV$ , cutting each other in  $S''$ , then  $S''$  is the feat of the luminous point in the plane  $ADEF$ .

Because the plane  $ABCD$  represents a rectangle, and  $V$  is the vanishing point of the one side, and  $X$  that of the other; all the lines drawn to  $X$  will represent right angles with the lines which vanish in  $V$ ; therefore  $Sa$  and  $AB$  represent a right angle in the plane  $ABCD$ . For the same reason,  $aS$  represents a right angle in the plane  $ABGF$ , and since the planes  $ABGF$  and  $ABCD$  are at right angles, the angle  $SaS'$  will represent a right angle; and because  $aS$  represents a perpendicular to  $AB$ ,  $aS'$  and  $SL$  will represent parallel lines; and since  $LS'$  and  $Sa$  have the same vanishing point  $X$ , the original of  $LS'$  is parallel to the original of  $Sa$ ; but  $Sa$  represents a perpendicular to the plane  $ABGF$ , therefore  $LS'$  also represents a perpendicular to the plane  $ABGF$ ; and because the point  $S'$  is in the plane  $ABGF$ ,  $S'$  is the feat of the luminous point  $L$ , in the plane  $ABGF$ . In the same manner it may be shewn that  $S''$  is the feat of the luminous point in the plane  $ADEF$ .

Given the representation  $cd$  of a line perpendicular to the original of the plane  $ABCD$ , and the vanishing point  $W$  of the line, and the point  $d$ , where the line meets the plane  $ABCD$ , a luminous point  $L$ , with its feat  $S$ , also upon the plane  $ABCD$ ; to find the shadow of the line  $CD$  upon the said plane.

Draw  $Sd$  and  $Lc$  to meet each other in  $e$ , then  $de$  will be the shadow of the line  $cd$ , as required. In the same manner, if  $fg$  represent a line perpendicular to the plane  $ABGF$ , and  $g$  the point where it meets the plane  $ABGF$ ,  $gb$  will be the shadow of the line, by drawing  $Lf$  and  $S'g$  to meet in  $b$ .

This method is general for any position of the original planes, with respect to the picture; and this position of the planes, in respect of each other, is that which most frequently occurs in practice.

Let  $ABCD$  (*fig. 5.*) be the inside of a room, shewing five sides, one,  $EFGH$ , being parallel to the picture, and the other four perpendicular to it;  $C'$  is the centre of the picture.

Let  $L$  be the light of a candle,  $S$  its feat upon the floor; then to find the feat of the light on all the other four sides. Through  $S$  draw  $ab$  parallel to  $V L'$ , the vanishing line of the horizon, cutting  $BF$  at  $a$ , and  $CG$  at  $b$ ; draw  $aS'$  and  $bS''$  parallel to  $YZ$ , the vanishing line of the two vertical planes; through  $L$ , the point of light, draw  $S'S''$ , then  $S'$  is the feat of the light in the plane  $ABFE$ , and  $S''$  the feat of the light in the plane  $CDHG$ . Produce  $CS$  to meet  $BC$  in  $c$ ; draw  $cd$  parallel to  $ZY$ , and join  $dC'$ ; draw  $S S^3$  parallel to  $YZ$ ; then  $S^3$  is the feat of the light in the plane  $A E H D$ ; let  $CS$  cut the line  $FG$  in  $e$ ; draw  $e S^4$  parallel to  $ZY$ , cutting  $L C'$  in  $S^4$ , then  $S^4$  will be the feat of the light on the plane  $EFGH$ . Then to project a prism standing perpendicular to any of these planes, suppose that

that which stands on the floor. From the feat *S* draw *Si*, meeting *C G* in *o*; draw *or* parallel to *Z Y*, and draw the ray *L m r*, and *r* will be the shadow of the point *m*; draw *S b*, cutting *C G* in *p*; draw *ps* parallel to *Y Z*, and draw *L n*, cutting *ps* at *s*; then *s* is the shadow of the point *n*; also draw *S g*, meeting *C G* in *q*; draw *qt* parallel to *Z Y*, and draw *L k*, meeting *qt* at *t*, then *t* is the shadow of the point *k*; join *rs* and *st*, which complete the whole shadow of the prism upon the floor, and on the wall.

The principle of finding the shadows of the prisms on the other sides, is the same, and will be obvious to inspection. The truth of the method has already been shewn.

**SHADOW**, in *Geography*. The inhabitants of the globe are divided, with respect to their shadows, into *Afcii*, *Amphicii*, *Heterocii*, and *Pericii*.

**SHADOW**, in *Painting*, denotes an imitation of a real shadow, effected by gradually lightening and darkening the colours of such figures as by their disposition cannot receive any direct rays from the luminary supposed to enlighten the piece. The management of the shadows and lights makes what painters call the *clair-obscur*: the laws of which see under the article *CLAIR-OBSCUR*.

**SHADOWS**, *Genesis of Curves* by. See *CURVE*.

**SHADOWS**, *Blue*. See *BLUENESS*.

**SHADUAN**, in *Geography*, a small island in the Red sea. N. lat.  $27^{\circ} 28'$ . E. long.  $33^{\circ} 58'$ .

**SHADWELL**, THOMAS, in *Biography*, a dramatic writer, and poet-laureat to king William III., was descended of an ancient family in Staffordshire, and was born about the year 1640, at Lanton-hall, in Norfolk, a feat belonging to his father, who was bred to the law, but having an ample fortune did not practise, choosing rather to serve his country as a magistrate. He was in the commission for three counties, *viz.* Middlesex, Norfolk, and Suffolk, and discharged the duties of the office with distinguished ability, and the most perfect integrity. In the civil wars he had been a considerable sufferer for the royal cause, so that having a numerous family, he was reduced to the necessity of selling and spending a considerable part of his estate to support it. In these circumstances he resolved to educate his son to his own profession. He was sent for preparatory studies to Caius college, Cambridge, and was afterwards entered at the Temple, but becoming acquainted with some of the wits of that time, he deserted his profession and devoted himself to literature. It was not long before he became eminent in dramatic poetry, and he appeared before the public as the writer of a comedy entitled "The fullen Lovers," or "The Impertinents," which was acted in the duke of York's theatre, and in 1668 it was printed. The success of this piece encouraged the author to proceed, and he from this period rapidly brought out plays, chiefly of the comic kind, till he had reached the number of seventeen. His model was Ben Jonson, whom he imitated in drawing humorous characters, rather from his own conceptions than from nature; and though his name has not been transmitted to posterity with much encomium, and his works have long since disappeared from the stage, yet some of his delineations are said to display much real humour. Lord Rocheller has given him a respectable place among his contemporaries; he says,

"None seem to touch upon true comedy,  
But basily Shadwell, and slow Wycherly."

As every one in those days was of necessity a party man, Shadwell ranked himself among the Whigs, and in consequence of this he was set up as a rival to Dryden. Hence there grew a mutual dislike between them, and upon the

appearance of Dryden's tragedy, entitled the "Duke of Guise," in 1683, Shadwell was charged with having the principal part in writing a piece, entitled "Some Reflections on the pretended Parallel in the Play called the Duke of Guise, in a Letter to a Friend," which was printed the same year. Dryden wrote a vindication of the Parallel, and a considerable storm was raised both against Shadwell and his friend Hunt, who assisted him in it, and who on this occasion was forced to fly into Holland. Dryden, by way of revenge upon Shadwell, wrote the bitterest satire against him that ever was penned; this was the celebrated *Mac-Flecknoe*.

In 1688 Shadwell was appointed to succeed his rival Dryden in the laureatship, an honour which he did not enjoy many years. He died suddenly in the year 1692, in the fifty-second year of his age, at Chelsea, and was interred in the church there. Dr. Nicholas Brady preached his funeral sermon, in which he assures us, "that the subject of his discourse was a man of great honesty and integrity, and had a real love of truth and sincerity; an inviolable fidelity and strictness to his word; an unalterable friendship wherever he professed it; and a much deeper sense of religion, than many others have who pretend to it more openly." The titles of Shadwell's plays are given in the *Biographia Dramatica*. An edition of his works, consisting of those plays and miscellaneous poems, was printed in 1720, in four vols. 8vo. The earl of Rochester, in speaking of Shadwell, says, "If he had burnt all he had written, and printed all he spoke, he would have had more wit and humour than any other poet."

**SHADWELL**, in *Geography*, a parish in the Tower division of the hundred of Ossulston, and county of Middlesex, England, is situated about two miles and a half E. by S. from St. Paul's cathedral. It was formerly called Chadwell, as is supposed from a spring dedicated to St. Chad, and constituted a hamlet in the parish of Stepney, till separated from it, and made parochial, in 1669. The extent of this parish is very small, being only 910 yards in length, and 760 in breadth, and is wholly covered with houses, except a few acres, called Sun Tavern fields, which are appropriated as rope-walks. That portion of it which adjoins the Thames, and is called Lower Shadwell, is chiefly inhabited by tradesmen, and manufacturers connected with the shipping; such as ship-chandlers, biscuit-bakers, wholesale butchers, malt-makers, sail-makers, anchor-smiths, coopers, &c. A market which had been formerly held at Shadwell under the authority of a charter of king Charles II., but which was long disused, has been revived within the last few years. The church, dedicated to St. Paul, is a modern structure of brick. The living is a rectory in the gift of the dean of St. Paul's. In Shakspeare's walk is a meeting-house for Presbyterian dissenters, opened only on Sunday evenings, when sermons are delivered by dissenting ministers of different denominations, for the support of a charity-school, in which 50 boys and 20 girls are clothed and educated. Here are also a Calvinist meeting-house, and a chapel for Wesleyan Methodists, who have a Sunday-school attended by above 100 children. A third charity-school, founded in 1712, and partly endowed by queen Anne, provides clothes and education for 80 boys and girls.

The Shadwell water-works, which were established in 1669, and served a district containing 8000 houses, have been lately disused; the premises having been purchased by the East London Water-works' company, by whom this parish and its neighbourhood are now supplied with water. In Sun Tavern fields is a mineral spring, called the Shadwell Spa, which long sustained a high character for its medicinal qualities,

qualities, but it has lately fallen into disrepute. Barracks for the accommodation of the Chinese and Lascar sailors, during their stay in England, have been recently erected here, and frequently lodge upwards of a thousand persons. According to the parliamentary returns of 1811, Shadwell parish contains 1694 houses, and 9855 inhabitants. Lyfons' Environs of London, 4to. 1795. Supplement, 1811. Stow's History of London, folio.

SHADWICKS, a town of America, in North Carolina; 10 miles W.S.W. of Hillsborough.

SHAFITES, in the *History of Mahometanism*, the followers of Mohammed Ebn Edris al Shafei, the author of the third orthodox sect, who were formerly spread into Mawara'nahr, and other parts eastward, but are now chiefly of Arabia. Al Shafei was born either at Gaza or Afcalon, in Palestine, in the year of the Hegira 150, on the same day in which, as some say, Abu Hanifa, the founder of the Hanefites, the first of the four orthodox sects, died; and was carried to Mecca at two years of age, where he was educated. He died in 204, in Egypt, whither he went about five years before, though Abulfeda says he lived 58 years. This doctor was very highly esteemed for his excellency in all parts of learning, inasmuch that his contemporary, Ebn Henbel, used to say that he was as the sun to the world, and as health to the body. Al Shafei is said to have been the first who discoursed of jurisprudence, and methodized that science; and accordingly it was wittily said of him, that the relators of the traditions of Mahomet were asleep, till Al Shafei came and awoke them. He was a great enemy to the scholastic divines. It is said of him, that he used to divide the night into three parts; one for study, another for prayer, and the third for sleep. It is also related of him, that he never so much as once swore by God, either to confirm a truth, or to assert a falsehood; and that being once asked his opinion, he remained silent for some time; and when the meaning of his silence was demanded, he answered, "I am considering first whether it be better to speak or to hold my tongue." The following saying is also recorded of him, "Whoever pretends to love the world and its creator at the same time is a liar." Sale's Koran, Int.

SHAFERS, in *Geography*, a town of Pennsylvania; 48 miles N.E. of Easton.

SHAFT, in *Building*. The *shaft of a column* is the body of it; thus called from its straightness; but by architects more frequently the *just*. See the dimensions under COLUMN.

SHAFT is also used for the spire of a church-steeple; and for the shank or tunnel of a chimney.

SHAFT, or *Tunnel-Pit*, is the well through which the stuff, excavated from a tunnel, is drawn up to the surface.

SHAFT of a *Mine*, is the hollow entrance or passage into a mine, sunk or dug to come at the ore.

In the tin-mines, after this is sunk about a fathom, they leave a little, long, square place, which is called a *shamble*.

Shafts are sunk some ten, some twenty fathoms deep into the earth, more or less. Of these shafts, there is the landing or working-shaft, where they bring up the work or ore to the surface; but if it be worked by a horse engine or whim, it is called a whim-shaft; and where the water is drawn out of the mine, it is indifferently named an engine-shaft, or the rod-shaft. See MINE and QUARRY.

SHAFT, in *Agriculture*, a name provincially applied to a handle of a tool; as a spade, fork, &c.

SHAFTS of *Carts and Waggons*, the parts or poles be-

tween which the thill-horses draw. The manner in which the fore-horses are attached to these shafts, when there are more than the thill-horses in the teams, is a matter of great consequence; as the weight or pressure on them is more or less, according to its nature, and the way in which it is performed. See THILL-Horses and WAGGON.

SHAFT-*Drain*, that sort which is effected by carrying a fort of shaft or pit down to the porous stratum below, and which is in use where a superficial descent cannot be had for the collected waters, and an open stratum lies beneath the subsoil, ready to receive it. A communication between them becomes here of high advantage, as the cost and attention of raising the water by machinery may thereby be avoided. In cases of this kind, Mr. Marshall advises the drainer to ascertain the lowest point of the scite to be improved; and there, says he, sink a shaft down, and into the receiving stratum, and fill it up to within a few feet of the surface, with rough stones, the roots of trees, or other open materials; and, on the top of these, form a filter, with heath and gravel, or other substances, that will prevent earthy matter, or water in a foul state, from entering the shaft: and to this filter lead the collected waters. And that where the water is collected by the means of covered drains, and where the filter also has a covering placed over it, the entire process will be free from external injury; and a work of this kind may remain unimpaired for ages. But even if the waters were collected by open drains, and the filter were suffered to remain in a state of neglect, until the shaft, in process of time, should become defective, the remedy would be easy. Embrace, says he, a dry season to re-open the shaft, and to cleanse it, and the materials with which it may be filled, from their impurities; and thus restore it, at a small expence, to its original state of perfection. It is further stated also, that if the scite of improvement be liable to any other surface-water, than what falls on its own area, such water ought to be conducted away from it superficially, by cutting it off at such a height as will gain a sufficient fall. And that where the quantity of water, which descends into it subterraneously, (or would descend, if a free passage were opened for it,) should be found to be too copious to be readily discharged by a shaft-drain, in the manner here proposed, proper efforts should be used to cut off the supply, or as much of it as may be, by a perforated trench or otherwise, at a sufficient height to be able to convey it away superficially; and with a sufficient fall, to prevent its entering the area to be improved; which will thus have only its own superfluous waters to discharge by the shaft. He is desirous to clear the way which leads to this valuable improvement, as he is convinced that there are many instances in which it might be applied with great profit. Many of the low, flat-lying, moory vallies of Norfolk, from whose bases superficial drains would be difficult to make, have for their substructures, it is probable, he says, insatiable depths of sand; and that, in every district of the island, such objects as are proper for this practice may be found.

SHAFTESBURY, *Earl of*, in *Biography*. See COOPER.

SHAFTESBURY, or SHAFTESBURY, in *Geography*, a borough and market-town in the hundred of Upwimborne, Shilton division of the county of Dorset, England, is situated at the distance of 28 miles N.N.E. from Dorchester, and 101 miles W.S.W. from London. Concerning the origin of this town much difference of opinion prevails. While some authors ascribe its foundation to Cicuber, Lud, or Cassibelan, supposed kings of the Britons, many years previous to the birth of Christ; others limit its antiquity to the reign of Alfred. This last opinion

is supported by Camden, upon the evidence of an inscription mentioned by William of Malmbury, which seems to point out Alfred himself as the founder, and is certainly much more probable than those which rest on the fanciful speculations of Jeffrey of Monmouth. There are circumstances, however, indicating Roman habitation on the site of Shaftsbury; and assuming this as a fact, some later writers contend that the words of the inscription, "Aelfredus rex fecit hanc urbem," are only intended to denote that Alfred renewed or repaired this city. But whatever may have been its condition previous to that monarch's reign, it was then only that it first attained any authenticated degree of celebrity, by the foundation of a monastery for nuns of the Benedictine order. This convent was indubitably the work of the great prince above-mentioned, as the charter of foundation, appointing his daughter Ethelgeda abbess, is yet extant. It was originally dedicated to the Virgin Mary, and became one of the richest and best endowed nunneries in England, occupied a great extent of ground, and possessed a vast number of offices and apartments within its precincts. The abbess was among the number of those who held a whole barony in capite, and was in consequence liable to serve in parliament, though excused on account of her sex. She had writs, however, directed to her, to send her quota of men into the field, according to her knight's fees. On the translation of the body of Edward the Martyr hither, from Wareham, this monastery assumed the name of that saint, which it retained till the dissolution. Many miracles are said to have been wrought at his shrine, which was visited by an immense concourse of pilgrims, among whom was the illustrious Canute, who died here. After the Conquest, this convent was for some time neglected; but the patronage of succeeding monarchs soon restored it to celebrity, and conferred upon it such extensive donations in land, that it became proverbial to say, "that if the abbot of Glastonbury might marry the abbess of Shaftsbury, their heir would have more land than the king of England." At the dissolution, the nuns amounted to fifty-four in number, and enjoyed a revenue valued by Speed at 1329*l.* 1*s.* 3*d.* The last abbess was Elizabeth Zouche, who had an yearly pension assigned to her of 133*l.*

Shaftsbury is a very ancient borough by prescription, being mentioned as such in Domesday Book. It was not, however, incorporated by regular charter till the reign of queen Elizabeth, who confirmed all the privileges it enjoyed by custom, and vested the government in a corporation, consisting of a mayor, recorder, twelve aldermen, a bailiff, and common council-men. That charter has since been confirmed by kings James I. and Charles II., with little variation. Henry VIII. made this town the seat of a suffragan bishop, but it did not retain its episcopal dignity above a few years. Shaftsbury has sent two members to parliament since the 25th year of Edward I. They are elected by the inhabitants paying scot and lot, who are estimated at about 300 in number, and are returned by the mayor. Shaftsbury has a weekly market on Saturday, and one annual fair; and according to the parliamentary returns of 1811, contains 515 houses, and a population of 2159 persons.

The town of Shaftsbury is most pleasantly situated, being built on a very lofty eminence, which commands an extensive prospect over the three adjoining counties of Dorset, Somerset, and Wilts. From the irregularity and narrowness of most of the streets, and the mean character of the buildings, however, it presents but an indifferent appearance. In ancient times it was more flourishing and important than at

present; containing, besides the abbey-church, twelve others, several chantries and fraternities, and a priory or hospital of St. John the Baptist. Of these public structures only four churches remain, respectively dedicated to St. Peter, the Holy Trinity, St. James, and St. Rumbald. The principal of them is St. Peter's, which is a building of considerable antiquity, and discovering much elegance in its symmetrical proportions and ornaments; but the greater part of it is defaced by modern alterations. Of the abbey scarcely a vestige is visible, the whole having been demolished soon after the dissolution, except the high embattled wall, supported by buttresses, which formerly inclosed the park, and is still in part standing on the side next the town. The other principal buildings of Shaftsbury are the town-hall, a free-school, two alms-house tenements, and three meeting-houses, for Presbyterians, Methodists, and Quakers.

The manor of Shaftsbury appears from Domesday Book to have been very anciently divided into two moieties, one of which belonged to the crown, and the other to the abbey. The abbey manor was surrendered in the 30th year of Henry VIII., whose successor granted it to Thomas Wriothesley, earl of Southampton, together with the town, borough, site, and precincts of the monastery. From him it passed to sir Thomas Arundel, and afterwards to the earls of Pembroke, by one of whom, Philip, the royalty of the manor, and borough manor, were sold to Anthony Ashley Cooper, earl of Shaftsbury, in whose family they still continue.

West from the town is an eminence called Castle Green, which is supposed to have received that appellation from its having been the site of an ancient castle, though history is silent respecting any such structure belonging to Shaftsbury. On the brow of this hill is a small mount, surrounded by a shallow fosse, which may have belonged to it, but it is commonly regarded as a Roman intrenchment. Tradition reports that the old town stood here, and it is certain that it occupied somewhat different ground from the site of the present buildings. The immediate vicinity of Shaftsbury is noted as the birth-place of the Rev. James Granger, author of the celebrated Biographical History of England. Beauties of England and Wales, vol. iv. by John Britton and E. W. Brayley, 8vo. 1803. Hutchins's History of Dorsetshire, fol. 1776, 2d. edit. 1797. History of the Ancient Town of Shaftsbury, 12mo. 1808.

SHAFTSBURY, a considerable and flourishing post-town of America, in the county of Bennington, Vermont, having Arlington on the north, and Bennington on the south, and containing 1973 inhabitants.

SHAG ISLAND, an island near the entrance into Christmas sound, on the S. coast of the island of Terra del Fuego; 4 miles N.E. of York Minder.

SHAGGE, or SHAG, in *Ornithology*, a name by which we call a water-fowl common on the northern coasts, and called by Mr. Ray *corvus aquaticus minor*, or the lesser cormorant, being properly a bird of the cormorant kind, or the *pelicanus graculus* of Linnæus.

It is somewhat larger than the common duck, and weighs about four pounds; its beak is straight and slender, and is not flattened, but roundish; it is four inches long, and is hooked at the end; its mouth opens very wide, and its eyes are small; the head is adorned with a crest, two inches long, pointing backward; the whole plumage of the upper part of this bird is of a fine and very shining green, the edges of the feathers a purplish-black; but the lower part of the back, head, and neck, wholly green; the belly dusky, and the legs black. It builds in trees as the common cormorant, swims with the head erect, and is very difficult to be

shot;

shot; because, when it sees the flash of a gun, it pops under water, and does not rise but at a considerable distance.

SHAGR, in *Geography*, a town of Syria, in the pachalic of Aleppo; 40 miles W. of Aleppo. N. lat. 35° 45'. E. long. 36° 25'.

SHAGREEN, or CHAGREEN, derived from the Tartar *şagbrè*, a kind of grained leather, prepared in Astrachan, chiefly by Tartars and Armenians, and mostly used in the covers of cases, books, &c. It is very close and solid, and covered over with little roundish grains, or papillæ. It is brought from Constantinople, Tunis, Tripoli, Algiers, and some parts of Poland.

There has been a dispute among authors, what the animal is from which the shagreen is prepared? Rauwolf assures us it is the onager, which, according to him and Bellonius, is a kind of wild ass. Vide Ray, *Synops. An. Quad.* p. 63.

It is added, that it is only the hard part of the skin which is used for this purpose. Or, it is that part of the skin that grows about the rump: that of horses is said to be equally good. There are large manufactures of it at Astrachan, and in all Persia. Borel says, it is the skin of a sea-calf; others, of a kind of fish, called by the Turks *şagrain*, whose skin is covered with grains; and those so hard, that they will rasp and polish wood.

There is also a sort of shagreen, which was formerly made of the skin of the squatina: in English, the monk or angel-fish, but now of that of the greater dog-fish. Vide Willughby *Ichth.* p. 80.

SHAGREEN, *Manner of preparing.* The process for making shagreen is as follows: of horse-hides and ass-hides the hinder back-piece, cut off immediately above the tail in nearly a semi-circular form about an arshine and a half upon the crupper, and rather less than an arshine along the back, is selected as the only part that is useful, and the rest is thrown away. The back pieces thus cut out are laid in a vat filled with clean water, and left in it several days successively, till they are thoroughly soaked, and the hair comes freely off. Then the hides are taken one by one out of the vat, spread against a board set slanting against the wall, one corner of it reaching over the edge of the board where it is fastened; and in this position the hair is scraped off with a blunt scraper, urak, and with the hair the upper pellicle; and the cleansed skin is laid again in clean water to soften. This done, they take it a second time out, spread one piece after another in the manner before described, scrape now the flesh-side with the same scraping-iron, and the whole skin cleaned again on the hair-side with great care, so that nothing now remains of the softened skin but the clean finewy web which serves for parchment, consisting of thick fasciuli of mellow fibres, resembling a hog's bladder softened in water. After this preparation they immediately take in hand certain frames, pæltzi, composed of a straight piece and a semi-circular bow, forming therefore nearly the shape of the skin, which is stretched in it with strings as even and uniform as possible; and during this operation is sprinkled between whiles with fair water, that no part of it can dry and occasion an unequal extension. In like manner they finally wet them when the whole stock of skins is stretched, and carry all the thoroughly wetted skins into the work-room. There the frames are one by one laid flat on the floor, so that the flesh-side of the stretched skins is turned undermost. The other side is now thick strewed over with the black, very smooth, and hard feeds of a species of the herb goose-foot, or the greater orach (*chenopodium album*), which the Tartars call alabuta, and which grows in great abundance, and almost to man's height, about the southern Volga in farm-

yards and gardens: and that these may make a strong impression on the skin, a felt is spread over them, and the feeds trod in with the feet, by which means they are impressed deeply into the very yielding skins. Then, without shaking off these feeds, the frames are carried again into the open air, and set leaning against a fence or a wall to dry, in such manner that the sides covered with the feeds face the wall and cannot be shone on by the sun. In this situation the stretched skins must dry for several days successively in the sun, till no trace of moisture is perceptible in them, and they may be taken out of the frames. Then, when the impressed feeds are beaten off from the hair-side, it appears full of little pits and roughnesses, and has got that impression which the grain of the shagreen ought to produce when the true polish has been given to the skin by art, and the ley now to be mentioned has been used previous to the staining.

The polish is done on a stretching-bench, or a board on tressels, furnished with a small iron hook, and covered with some thick felts or voiloks of sheep's wool, on which the dried shagreen-skin may lie soft. This is hung in the middle, by a hole which has been occasioned by the string in the stretching, to the hook, and fastened at the end by a string with a weight or a stone, by means of which the skin is allowed to move to and fro, but cannot easily be shoved out of its proper situation. This done, the polishing or rasping is performed by two several instruments; the first is called by the Tartars tokar, being an iron, crooked at one end like a hook and sharpened. With this the surface of the shagreen is scraped pretty sharply, in order to remove the most prominent rugosities, which from the horny hardness of the dried skin is no easy matter, and in which great care must be taken not to shave away too deeply the impressions of the alabuta-feeds, of which there is imminent danger if the iron be kept too sharp. As the blade of this iron is very narrow, it will make the shagreen rather uneven, and therefore after it, must be used the other scraper, or urak, by which the whole surface acquires a perfect equality, and only a slight impression remains of the feeds, exactly as it ought to be. After all these operations the shagreen is laid again in water, partly for rendering it supple and partly to make the elevated grain appear; for the feeds having caused pits in the surface of the skin, the interstices of these pits have lost their prominent substance by the polishing or shaving, and now the points that were pressed down, having lost nothing of their substance, spring up above the shaved places, and thus form the grain of the shagreen. To this end the pieces of shagreen are left to soften twice 24 hours in water, and are floated several times afterwards in a strong and hot ley, which is obtained by boiling from an alkalescent saline earth, schora, found about Astrachan. From this ley the skins are bundled warm one on another, and thus suffered to lie some hours, by which they swell up and are softened in an extraordinary manner. Again, they are left to lie 24 hours in a moderately strong brine of common salt, by which they are rendered fine and white, and excellently adapted to receive any agreeable colour, which the workman hastens to give them as soon as they are come out of the pickle. The colour most commonly communicated to the fine shagreen is the sea-green, as the most beautiful. But the expert shagreen-makers have the art of making also black, red, blue, and even white shagreen.

For the green dye, nothing more is necessary than fine copper-silings and sal-ammoniac. As much of the latter is melted in hot water as the water will admit. With this sal-ammoniac water the shagreen skins, still moist from the brine, are brushed over on the ungrained flesh-side, and when they are thoroughly wetted, a thick layer of copper-silings

is strewed over them, the skins doubled together, so that the strewed side lies inwards, and then each, being rolled apart in a little felt or voilok, they lay all these rolls orderly on one another, and press them equally by a considerable and uniformly pressing weight, under which they must lie twenty-four hours. In this time the sal-ammoniac water dissolves enough of the cupreous particles for penetrating the skin with an agreeable sea-green colour; and though it be not strong enough the first time, yet a second layer of copper-dust, wetted with sal-ammoniac water, with which the skins must lie again twenty-four hours, will be quite sufficient for staining them thoroughly; when they may be properly cleaned, spread out, and dried. For giving the blue colour to shagreen, they use only indigo, which to this end is not so prepared as for the silk and cotton-dyers, but entirely without bones, only by strenuous friction, is mingled and dissolved with the other ingredients. They put about two pounds of finely grated indigo in the kettle, pour cold water on it, and stir it till the dye begins to dissolve. They next dissolve in it five pounds of pounded alakar, which is a sort of barilla, or raw foda-salt, burnt by the Armenians of Kitzliar, and a worse kind by the Kalmucks, adding two pounds of lime and one pound of virgin honey, all thoroughly stirred, and set in the sun for several days, during which the stirring is frequently repeated. The shagreen skins which are to be made blue must be put only in the natrous ley, schora, but not in the brine made of common salt. They are again folded up wet, and sewed close together round the edges, with the flesh-side turned inwards, and the shagreened hair-side outwards, upon which they are three times dipped in succession in an old store-dye kettle, at every time pressing out the superfluous dye; lastly, they are all brought into fresh dye, which must not be pressed out, and with which the skin is hung up in the shade to dry; they are, for the last time, cleaned, ornamented on the edges, and reduced to order. For the black shagreen they employ nut-galls and vitriol in the following manner: the skins, still moist with the brine, are thick strewed with finely powdered nut-galls, folded together, and laid one on another twenty-four hours. In the mean time a new ley of bitter earth-salts or schora is boiled and poured hot in little troughs or trays. In this ley each skin is waved to and fro several times, is again strewed with pulverized nut-galls, and again laid in heaps for some time, that the virtue of the galls may thoroughly penetrate the skins, which are then suffered to dry, and are beat out to clear them from the galls. When this is done, the skin is smeared on the shagreen-side with mutton suet, and laid a little in the sun, that it may absorb the fat. It is the custom, likewise, with the shagreen-makers to roll up each skin apart, and to squeeze and press it against some solid body, in order to promote the absorption of the unctuous particles. The surplus is again scraped off with a blunt wooden scraper. This being done, and the skin having lain a little while, a sufficient quantity of iron-vitriol is dissolved in water, with which the shagreen is rubbed on both sides, by which it soon acquires a beautiful black colour: and now the edges and other defective parts are dressed. To obtain white shagreen, the skin must first be steeped in strong alum-water on the shagreened side. Having imbibed this, the skin is well rubbed on both sides with a paste of wheaten flour, and left to dry with it; then all the paste is washed away with alum-water, and the skin set to dry completely in the sun. As soon as the skins are dry, they are gently smeared over with clean melted mutton fat, leaving them in the sun to imbibe it, and are worked and pressed with the hands to promote this effect. Afterwards the skins are fastened one by one on

the above-mentioned stretching-bench, warm water is poured over it, and the superfluous fat scraped off with obtuse wooden instruments, to which the warm water just poured on has much assisted. By this process the shagreen receives a fine white colour, and needs only, in conclusion, to be dressed and rubbed. This whitening, however, is given to the shagreen, not so much that it may continue in that state, but in order to impart to it a beautiful high red hue, as this end could not be obtained to such perfection without that preparation. But the shagreens intended to be stained red must not be brought out of the natrous bitter salt ley into the brine, but must be made white, in the manner above-described, and afterwards supplied with the brine, in which they are left to lie about twenty-four hours, or less, from the dye. The dye is made with cochennille or kirmis, as the Tartars call it. The operation is begun by boiling for a full hour about a pound of the dried herb tsehagan, which grows plentifully on the salt steppes about Astrachan, and is a sort of kali, in a kettle large enough to contain about four common vedros of water, by which the water acquires a greenish colour. The herb is then taken out, and about half a pound of grated cochennille put into the kettle, with which the above decoction must boil another full hour, diligently stirring it on the fire, that the kettle may not boil over. Lastly, to this are added fifteen or twenty grains of the material which the dyers call lutter (perhaps orpiment), let the dye boil a little more, and then take the fire from under the kettle. Then the skins taken out of the brine are laid separately in trays, pouring the dye upon them four times, rubbing it in with the hands, that it may be equally spread and imbibed, pressing it out every time, which done, they are ready for drying and ornamenting, and sell much dearer than the others.

The best shagreen is that brought from Constantinople, of a brownish colour; the white is the worst. It is extremely hard; yet, when steeped in water, it becomes very soft and pliable; whence it is of great use among case-makers. It takes any colour that is given it, red, green, yellow, or black. It is frequently counterfeited by morocco, formed like shagreen: but this last is distinguished by its peeling off, which the first does not.

SHAGUM, in *Geography*, a river of America, which runs into lake Erie, N. lat.  $41^{\circ} 40'$ . W. long.  $81^{\circ} 21'$ .

SHAH, the Persian title corresponding to king, and equivalent to khan. (See CHAM.) Nevertheless, the most absolute Persian monarchs, who have never assumed any other title than that of shah, have permitted the governors of provinces in their empire to take that of khan, which is its equivalent, and which they have ever affected. Even in our time, the governors of the provinces of Ghilan, Mazanderan, &c. who have no more authority in Persia, than the pachas in Turkey, take the title of khan, the reason of which it is not easy to assign.

SHAHABAD, in *Geography*, a town of the kingdom of Candahar; 40 miles S.W. of Cabul.—Also, a town of Hindooistan, in the circle of Sirhind; 42 miles E.S.E. of Sirhind.—Also, a town of Hindooistan, in Oude; 45 miles W. of Kairabad. N. lat.  $27^{\circ} 40'$ . E. long.  $80^{\circ} 20'$ .—Also, a town of Hindooistan, in Oude; 25 miles S.W. of Mahomdy.

SHAHAMA, a name given to a colossal statue, cut in a mountain in the neighbourhood of the ancient city of Bamiyan, in the East Indies. This city, (which is described in our article BAMIAN,) is eight days' journey north-westerly from Cabul, and is rarely visited by Europeans, though highly deserving of examination. The statue in question is accompanied by another, called Salsala. Native travellers

differ as to their height; from fifty cubits to eighty ells. Their origin, age, and sex, are also variously related. The few Hindoos who live in the neighbourhood, say, they are the statues of one of their heroes named Bhim, and his consort. Bhim is one of the five famous Pandus. (See PANDU.) The followers of Budha call them by the names first mentioned. The Mahommedans say, they are of Adam and Eve; and a third statue, half a mile distant, about twenty feet high, they say is of Seth, their son. The author of a celebrated Persian dictionary, entitled "Farhang Jehangiry," says they existed in the time of Noah; but gives them other names. There can be little doubt but these statues, and the wonderful excavations of the city of Bamian, scooped, like Thebes, out of a mountain, were executed by the same indefatigable race of workmen, who in the more southern parts of India constructed the gigantic statues in the similar caverns at Kenera, on the island of Salfette, near Bombay, in the province of Kanara, and at Karly; all believed to be of Jaina or Budhaic origin. See JAINA, KARLY, and KENERA.

**SHAHBUNDER**, in *Geography*, a town of Hindoostan, in the province of Tatta; 45 miles S.S.W. of Tatta.

**SHAHDOURAS**, a town of Hindoostan, in the circar of Sirhind; 10 miles N. of Tannafar.

**SHAHG**, a town of Hindoostan, in Myfore; 18 miles S. of Vencatighery.

**SHAHJEHAN**, a town of Hindoostan, in Bahar; 18 miles N.W. of Bahar.—Also, a town of Hindoostan, in Rohilcund; 45 miles S. of Pillibeat.

**SHAHJEHANPOUR**, a town of Hindoostan, in Malwa; 20 miles N.E. of Ougein. N. lat.  $23^{\circ} 26'$ . E. long.  $76^{\circ} 18'$ .—Also, a town of Hindoostan, in Oude; 30 miles S.E. of Fyzabad. N. lat.  $26^{\circ} 26'$ . E. long.  $82^{\circ} 40'$ .—Also, a town of Hindoostan, in Mewat; 20 miles W. of Alvar.—Also, a town of Hindoostan, in Bahar; 14 miles S.S.E. of Patna. N. lat.  $25^{\circ} 24'$ . E. long.  $85^{\circ} 30'$ .

**SHAHIGIAN**, a town of Persia, in the province of Khorasan, near Maru, which since is called *Maru Shahigian*.

**SHAHJOLE**, a circar of Bengal, bounded on the north by Rajeshy, on the east by Mahmudshi, on the south by Jeffere, and on the west by Kishenagur; about 30 miles long, and from 5 to 10 broad.

**SHAHISABI**, a town of Persia, in the province of Khorasan, on the borders of Bucharia; 80 miles N. of Maru.

**SHAHI-SHAK**, a town of Persia, in the province of Khorasan, on the borders of Bucharia; 5 miles N. of Maru.

In our didactic and elementary articles, we should not wish to confine ourselves to mere dry definitions of terms of art; but, having had some little experience, we would gladly assist students, by pointing out the means of acquiring the practical use of what we describe.

With regard to a *vocal* shake, we can do young fingers no greater kindness, than in referring them to the 3d chap. of Tosi's "Observations on florid Song," as admirably translated by Galliard, and illustrated with the notes of that able and experienced master.

**SHAHPOUR**, a town of Hindoostan, in Lahore; 30 miles W. of Nagorcote.—Also, a town of Hindoostan, in Lahore; 27 miles E. of Sealcot.

**SHAHR** and **VAN**, the ancient *Apollonia*, a town of the pachalic of Bagdad, 27 miles from Bacouba, which is nine furlongs from Bagdad, peopled by about 4000 Turks and Kurds, and is, upon the whole, a handsome little town, watered by two canals drawn from the Diala. At the distance of 18 miles is Kuzil Roobat, not so large as the former, situated in a sandy plain, about one mile from the river Diala. Khanakie is also a handsome little town, built on that branch of the Diala, which has its source in the mountains of Kurzend, 18 miles from Kuzil Roobat; it occupies both banks of the river, over which is a handsome bridge, and is surrounded by numerous gardens and plantations. Mendeli, about the same size as Solymania, is situated in one of the roads leading to Kermandhaw; and four furlongs on the Bagdad side is a fountain of naphtha. Thirteen leagues from Mendeli, and four from the foot of the mountains, is Bedri, the frontier town, in this quarter of the Turkish empire.

**SHAIGI**, a town of Nubia, on an island in the Nile; 130 miles E. of Dongala. N. lat.  $20^{\circ} 20'$ . E. long.  $50^{\circ} 45'$ .

**SHAIGOL**, a town of Persia, in the province of Khorasan; 10 miles S.W. of Maru.

**SHAIMA**, a town of Persia, in the province of Meceran, on the sea-coast; 200 miles W.S.W. of Kidge.

**SHAINT**, or **HOLY ISLES**, three small islands of the Hebrides, or Western isles, are situated in the channel between the isles of Lewis and Skye, in the parish of Lochs and district of Lewis. These islands are well known to mariners, and are remarkable for their fine sheep pasture. One of them, called St. Mary's island, has a small chapel upon it, dedicated to the Virgin, and bears marks of having been formerly better inhabited than at present. Sinclair's Statistical Account of Scotland, vol. xix. 8vo.

**SHAINYMALY**, a town of Hindoostan, in Coimbe-tore; 12 miles S. of Errood.

**SHAIZAR**, a town of Syria, in the pachalic of Damascus, on the Orontes; 20 miles N. of Hamah.

**SHAK**, a town of Persia, in the province of Schirvan; 20 miles N.W. of Schamachie.

**SHAKE**, in *Music*, is a grace, an embellishment of melody, of which the indication is a *tr*, or sometimes only *s*, the initial of the Italian term *trillo*, which implies the same thing. There are two kinds of shakes, the continued, and the transient. The continued shake, upon a long note, must be practised at first by incipients, slow, and accelerated by degrees. The effect of a shake is a rapid motion of two adjoining notes: as *de*, *be*, &c.

Tosi, after informing the student of the importance of the shake to fingers, says, "Let the master strive to enable his scholar to attain a shake that is equal, distinctly marked, easy, and moderately quick, which are its most beautiful requisites."

This excellent author describes the different kinds of shakes, and their preparation, that are worth cultivating, as well as those that are to be avoided. The free and open shake on the *whole tone* and the *semitone*, are certainly the principal.

The two tones or semitones that constitute the shake major or minor, should be equally loud and distinct; but above all, perfectly in tune with the notes of the general scale and particular key in which the performer is fingering. The Italians call a bad shake, or no shake at all, but a quivering upon the same note, *toffe da capra*, a goat's cough. If the finger is not possessed of a true and good shake, he or she had best refrain from ever attempting it; and if accustomed to elegant melody, and possessed of good taste and ornamental embellishments, the shake in songs of expression and pathos may be avoided with advantage.

As the acquiring of a good shake in fingering is a work of

Shakes upon keyed instruments are best practised at first with the second and third fingers; holding down at the same time the fifth below with the thumb, to keep the hand and the wrist quiet. And we recommend, contrary to the usual practice and precepts, beginning the shake with the lowest note; otherwise, in rapid transient shakes with semiquavers, there is not time for returning to the upper note; so that the shake is reduced to a mere appoggiatura. See GRUPPO and TRILL.

**SHAKER-PIGEON**, in *Ornithology*, a kind of pigeons, of which there are two sorts, the broad-tailed, and the narrow-tailed.

The first is the finest, and most valued. It has a beautiful long thin neck, which bends like the neck of a swan, leaning towards the back. It has a full breast, a very short back, and a tail consisting of a great number of feathers, seldom less than four-and-twenty, which it spreads in an elegant manner, like the tail of a turkey-cock, and bends it up so, that it meets the head. It is commonly all white, but sometimes is red, yellow, or blue-pied. The longer the neck of this bird is, the more it is valued.

The second, or narrow-tailed shaker, has a shorter and thicker neck and a longer back. It is esteemed by many a different species, but seems only a mixed breed with some other pigeon. They are called shakers, from a tremulous motion which they have with their necks when courting.

**SHAKERS**, in *Ecclesiastical History*, a sect which originated in Lancashire, with some deserters from the society of Quakers, or Friends, about the year 1747, and which continued for some time unconnected with every denomination of Christians. During this period, their testimony, derived, as they fancied and pretended, from what they saw by vision and revelation from God, was, "that the second appearing of Christ was at hand, and that the church was rising in her full and transcendent glory, which would effect the final downfall of Antichrist." From the shaking of their bodies in religious exercises, they were denominated Shakers, and by some persons they were called Shaking Quakers. The sect seems to have made no great progress until the year 1770, when the testimony originally announced was fully opened, according to the special gift and revelation

time, difficulty, and uncertainty of success, several ingenious and elegant cadences have been invented in order to evade the shake. A good shake well applied is certainly a great ornament; but it is a matter of brilliancy more than expression; *non dico niente*, it says nothing—according to modern Italian critics, and is seldom wanted except at the end of a formal cloze. Those who have a good shake, like persons with a fine set of teeth, are too ambitious of letting you know it. The different kinds of shakes are expressed in notes on the music-plates. The plain note and trill are at present thought more elegant, and are more frequently used than the sudden and long continued rapid motion of the common shake.

of God through Ann Lee, who was born of obscure parentage, at Manchester, about the year 1736; and who, having joined the society in 1758, became afterwards a distinguished leader among them. Her exercises, both of body and of mind, were singularly trying and severe for about the term of nine years; but she was thus prepared for receiving the testimony of God, against the whole corruption of man, in its root and every branch. Accordingly, her testimony was in the power of God, attended with the word of prophecy, and such energy of the Spirit, as penetrated into the secrets of the heart, and was irresistible, especially in those with whom she was united.

And from the light and power of God which attended her ministry, and the certain power of salvation transmitted to those who received her testimony, she was received and acknowledged as the *first Mother*, or spiritual parent in the line of the female, and the second heir in the covenant of life, according to the present display of the gospel. Hence among believers, she hath been distinguished by no other name or title than that of *Mother*, from that period to the present day. To such as addressed her with the customary titles used by the world, she would reply, "I am *Ann the Word*;" signifying that in her dwelt the *Word*.

In 1774, Ann Lee, with some of her followers, having been thought mad, and sorely persecuted, settled their temporal affairs in England, and set sail from Liverpool for New York. James Wardley and his wife remaining behind, were removed into an alms-house, and there died. The others, we are told, "being without lead or protection, lost their power, and fell into the common course and practice of the world!" Ann Lee and the brethren reached New York, after working a sort of miracle, for the ship sprung a leak on the voyage, and it is more than hinted, that had it not been for their exertions at the pump, the vessel would have gone down to the bottom of the ocean! She, however, left New York, and fixed her residence up the Hudson river, eight miles from the city of Albany. In this retired spot, her followers greatly multiplied, but she was not without bitter reproaches and manifold persecutions. She and the elders would delight in missionary journeys, being out for two or three years, and returning with wonderful account, of their success.

After Mother and the elders were released from prison, they again collected together at Water-Whet, where they were visited by great numbers from distant parts of the state of New York, Massachusetts, Connecticut, New Hampshire, and the district of Maine, who received faith; and through the power and gifts of God, which were abundantly manifested for the destruction of sin, and the salvation of souls, many were filled with joy unspeakable and full of glory, and increased in their understanding of the way and work of God.

Ann Lee died on the eighth day of the ninth month 1784. From the year 1780 to 1787 the credit of this sect revived in America, and the number of its adherents considerably increased.

The creed of the Shakers is very obscurely and mystically expressed. They seem to be believers neither of the Trinity nor of the Satisfaction. They deny also the imputation of Adam's sin to his posterity, as well as the eternity of future punishment. The tenets on which they most dwell are those of human depravity, and of the miraculous effusion of the Holy Ghost! Their leading practical tenet is the abolition of *marriage*, or indeed the *total separation* of the sexes. This circumstance of course attracts great attention, and they pride themselves on their superior purity. The essence of their argument is, that the *resurrection* spoken of in the New Testament means nothing more than *conversion*; our Saviour declares that *in the resurrection they neither marry nor are given in marriage*, therefore, on *conversion* or the *resurrection* of the individual, marriage ceases!!! To speak more plainly, the *single* must continue *single*, and the *married* must separate. Every passage in the gospel and in the epistles is interpreted according to this strange and unnatural hypothesis.

The system of the Shakers is thus pretty plainly described. "In the fulness of time, according to the unchangeable purpose of God, that same Spirit and Word of power, which created man at the beginning—which spake by all the prophets—which dwelt in the man Jesus—which was given to the apostles and true witnesses as the Holy Spirit and Word of promise, which groined in them waiting for the day of redemption—and which was spoken of in the language of prophecy as a woman traveling with child, and pained to be delivered, was revealed in a *woman*.

"And that *woman*, in whom was manifested that Spirit and Word of power, who was anointed and chosen of God, to reveal the mystery of iniquity, to stand as the first in her order, to accomplish the purpose of God, in the restoration of that which was lost by the transgression of the first woman, and to finish the work of man's final redemption, was *Ann Lee*.

"As a chosen vessel, appointed by divine Wisdom, she, by her faithful obedience to that same anointing, became the temple of the Holy Ghost, and the second heir with Jesus, her lord and head, in the covenant and promise of eternal life. And by her sufferings and travail for a lost world, and her union and subjection to Christ Jesus, her lord and head, she became the *first born of many sisters*, and the true mother of *all living* in the new creation.

"Thus the perfection of the revelation of God in this latter day, exceeds, particularly, in that which respects the most glorious part in the creation of man, namely, the woman. And herein is the most co-descending goodness and mercy of God displayed, not only in redeeming that most amiable part of the creation from the curse, and all the ferrows of the fall, but also in condescending to the lowest estate of the loss of mankind.

"So that by the first and second appearing of Christ, the foundation of God is laid and completed, for the full

restoration of both the man and the woman in Christ, according to the order of the new covenant, which God hath established in them for his own glory, and the mutual good and happiness of each other.

"And in this covenant, both male and female, as brethren and sisters in the family of Christ, jointly united by the bond of love, find each their correspondent relation to the first cause of their existence, through the joint parentage of their redemption.

"Then the man who was called Jesus, and the woman who was called Ann, are verily the two first foundation pillars of the church of Christ—the two anointed ones—the two first heirs of promise, between whom the covenant of eternal life is established—the first father and mother of all the children of regeneration—the two first visible parents in the work of redemption—and the invisible joint parentage in the new creation, for the increase of that seed through which all the families of the earth shall be blessed."

The Shakers record several cases which they pretend to be miraculous, but it is needless to enlarge on a system that is wholly founded in delusion.

SHAKERTOWN, in *Geography*, a town of Kentucky, in Mercer county, containing 268 inhabitants.

SHAKES, in *Ship-Building*, a name given to the cracks or rents in a plank, &c. occasioned by the sun or weather.

SHAKING, a disease in sheep, consisting of a weakness in their hind quarters, so that they cannot rise up when they are down. There has not hitherto been found any remedy for this disease. It is probably of the nature of palsy, and to be removed by strong nervous stimulant remedies.

SHAKLES, on board *Ship*. See SHACKLES.

SHAKRA, in *Geography*, a town of Arabia, in the province of Nedsjed; 120 miles N.E. of Faid.

SHAKSPEARE, WILLIAM, in *Biography*, an English dramatic poet, is justly esteemed the most eminent and most interesting author of the ancient or modern world. His writings have progressively risen in popular estimation in proportion as they have been studied and analysed. Some of his dramas are continually acted on the London and provincial stages; many critics and commentators, both English and foreign, have employed their pens, and exerted their faculties, in dissertations on the merits and defects of his productions. From the most trying and fastidious ordeal of investigation he has risen in glory and greatness; and may, at the present time, be justly pronounced pre-eminent and unrivalled as a dramatic poet.

To Englishmen his writings are singularly estimable; for they have conferred on the country a literary immortality, which nothing less than the dissolution of "the great globe itself" can annihilate. Nor is he exclusively endeared and valuable to the man of letters; but all classes of artists, and even many artizans, have derived both fame and emolument through the medium of his works. It has been often remarked, that the prophet is never honoured in his own country, or appreciated by his contemporaries. Although this maxim is now merely considered as figurative, and the age of, and confidence in, prophecy is past, yet it may be fully and strictly applied to the meritorious author. After decease, his whole merits are gradually unfolded; his talents and genius command admiration, and each reader and commentator seem eager to discover new beauties, and to point out hidden excellencies. Among the literary "worthies" of the world, from the days of Homer to Milton, no one has attained equal celebrity with Shakspeare. He now shines as the sun of the intellectual hemisphere, and every other poet seems to derive a reflected light from him, or moves in a less circumscribed orbit. Like divine nature, which was at once his

his guide and goddeſs, his writings excite admiration and delight, the more intently they are ſtudied. Prompted by inſpiration, and impreſſed with profound knowledge, with the keen and acute "poet's eye," he commanded every region of the terreſtrial globe, penetrated the hidden thoughts of man, gave to "airy nothing a local habitation and a name," and alligned to every paſſion and ſentiment "its true form and feature."

'Tis wonderful,

That an inviſible inſtinct ſhould frame him  
To poetry unlearned; honour untaught;  
Civility not ſeen in other; knowledge  
That wildly grew in him, yet yielded crops  
As though it had been ſown: for he could find  
"Tongues in trees, books in the running brooks,  
"Sermons in ſtones, and good in every thing."—  
Do not ſmile at me that I boaſt him off,  
For ye ſhall find he will outſtrip all praiſe,  
And make it halt behind him. DOVAſTON.

Heaven has him now: let our idolatrous fancy therefore ſanctify his reliques. Deſpairing to be his equals, let us profit by his precepts; ſeek to acquire his wiſdom; emulate his gentleneſs, talents, and honours. Conſcious of the comparative frigidneſs of our own faculties, let us warm our hearts at his celeftial fire, and kindle our ſouls at his unextinguishable flame! If enthuiasm be juſtifiable on any ſubject, the writer of the preſent article hopes to ſtand excuſed in giving this latitude to his feelings and expreſſions. He has to regret, with thouſands of others, that the ſubject of this memoir is only known in his writings, and that his perſonal hiſtory is as obſcure as that of Homer or Archimedes. Indeed, before we proceed farther, it is neceſſary to preface, that a ſingular and unaccountable myſtery is attached to Shakspeare's private life; and, by ſome ſtrange fatality, almoſt every document concerning him has either been deſtroyed, or ſtill remains in obſcurity. The firſt published memoir of him was drawn up by Nicholas Rowe, in 1709, nearly 100 years after the deceaſe of the poet; and the materials for this were furniſhed by Betterton, a player. It ſhould be remembered, that the age in which he lived was not the age of minute inquiry. From Rowe's account, and from other evidence, it is clear that our poet was not ambitious of poſthumous fame; that he diſregarded the eſtimation of after ages; that he was unconſcious of the high merit of his own writings; and that, though he was much in the public world, and died in comparative affluence, his private life and character were ſcarely noticed by the biographer or critic. To the man of taſte and refined ſenſibility, he has, however, bequeathed an inexhauſtible treaſure in his dramatic productions; and as theſe conſtitute an eſſential part of the well-ſtocked library, it is equally eſſential to record every fact, and inveſtigate every problematic ſtatement, relating to the inſeſſable author.

That he was born at Stratford-upon-Avon, in Warwickſhire, on the 23d of April 1564, is well aſcertained; and that he was baptized on the 26th of the ſame month, appears by the pariſh regiſter. He is there deſcribed as the ſon of John Shakspeare, who, according to Rowe, and moſt ſubſequent biographers, was "a conſiderable dealer in wool," and whoſe "family were of good figure and faſhion." Oppoſed to this ſtatement is that of John Aubrey, who entered himſelf as a ſtudent in the univerſity of Oxford, 1642, only 26 years after our poet's death, who derived *his* information from "ſome of the neighbours" of Shakspeare, and who appears to have made a practice of writing down every fact and tradition that he heard relating to public characters.

His account is entitled not only to recital, but to cautious conſideration.

"Mr. William Shakspear was borne at Stratford-upon-Avon, in the county of Warwick; his father was a butcher; and I have been told heretofore by *ſome of the neighbours*, that when he was a boy he exerciſed his father's trade, but when he kill'd a caſſe, he would doe it in a high ſtyle, and make a ſpeech. There was at that time another butcher's ſon in this towne that was held not at all inferior to him for a naturall witt, his acquaintance and coetanean, but dyed young. This Wm. being inclined naturally to poetry and acting came to London, I gueſſe about 18, and was an actor at one of the play-houſes, and did act exceedingly well. Now B. Jonſon was never a good actor, but an excellent inſtructor. He began early to make eſſayes at dramatique poetry, which at that time was very lowe, and his playes tooke well. He was a handſome well-ſhap'd man, very good company, and of a very readie and pleaſant ſmooth witt. The humour of — the conſtable in *A Midſummer Night's Dreame* he happened to take at Grendon in Bucks, which is the roade from London to Stratford, and there was living that conſtable about 1642, when I firſt came to Oxon. Mr. Jos. Howe is of that pariſh, and knew him." (See Warton's Life of Sir Thomas Pope.) "Ben Jonſon and he did gather humours of men dayly wherever they came. One time, as he was at the tavern at Stratford-upon-Avon, one Combes, an old rich uſurer, was to be buried; he makes there this extemporary epitaph:

'Ten in the hundred the devill allowes  
But Combes will have twelve, he ſweares and vowes:  
If any one aſkes who lies in this tombe,  
'Hoh!' quoth the devill, 'tis my John o'Combe.'

"He was wont to goe to his native country once a yeare. I thinke I have been told that he left 2 or 300 lib. per annum there and there-about to a ſiſter. I have heard ſir Wm. Davenant and Mr. Thomas Shadwell (who is counted the beſt comœdian we have now) ſay, that he had a moſt prodigious witt, and did admire his naturall parts beyond all other dramaticall writers. He was wont to ſay that he never blotted out a line in his life; ſayd Ben Jonſon 'I with he had blotted out a thouſand.' His comedies will remain witt as long as the Engliſh tongue is underſtood, for that he handles *mores hominum*; now our preſent writers reſpect ſo much upon particular perſons and coxcombeities, that twenty yeares hence they will not be underſtood.

"Though, as Ben Jonſon ſayes of him, that he had but little Latine and leſſe Greeke, he underſtood Latine pretty well, for he had been in his younger yeares a ſchoolmaſter in the country." The latter fact was communicated by Mr. Beeſon.

In another memorandum Aubrey ſtates, that

"Mr. William Shakspeare was wont to goe into Warwickſhire once a yeare and did comonly in his journey lye at this houſe in Oxon" (*i. e.* the Crown tavern, kept by the father of ſir William Davenant,) "where he was exceedingly reſpected. \* \* \* Now ſir Wm. would ſometimes, when he was pleaſant over a glaſſe of wine with his moſt intimate friends. — e. g. Sam. Butler (author of Hudibras) &c. ſay, that it ſeemed to him that he writ with the very ſpirit that Shakspeare, and ſeemed contented enough to be thought his ſon \* \* \*"—Theſe anecdotes are now publiſhed in "Letters written by eminent Perſons in the ſeventeenth and Eighteenth Centuries," three vols. 8vo. 1813.

This account is truly curious and intereſting; and in ſpite

spite of the scepticism of Dr. Farmer, in his "Essay on the Learning of Shakspeare," and of some other writers, the impartial reader must admit that it assumes the air of probability, candour, and truth. Aubrey might have erred in some points; particularly in saying, Shakspeare visited London at the age of eighteen, when the registry of his own baptism, and that of his twin-children, shew that he must have remained at home till the age of twenty. Again, it is very probable that he met with a constable at Grendon, or Long-Crendon, in Buckinghamshire, whose character he dramatised, not in "A Midsummer Night's Dream," but in "Much ado about Nothing," or in "Love's Labour's Lost." The extempore epitaph on John o'Combe is represented by Rowe, who gives it different to the above, as having been made during the life-time, and in the presence of the person commemorated, who is also said never to have forgiven the poet. In Aubrey's relation there is nothing improbable, nor unreasonable, in a poet producing such lines sportively over his cups, and among convivial friends: it is a smart epigram on an usurious character. Instead of leaving 300*l.* per annum to a sister, he bequeathed as much to his daughter, as will be shewn in the sequel. If there be any lurking prejudice against the profession of a butcher, let it be remembered, that the proud and ostentatious cardinal Wolfey was the son of a butcher; and that the parentage of a Homer, a Milton, and a Shakspeare, cannot be honoured or degraded by their ancestors.

"Honour and fame from no condition rise;  
Act well your part, there all the honour lies."

The house in which our poet was born has been occupied by a succession of butchers from time immemorial. Besides, it is not at all improbable that the butcher and the wool-stapler were united in one person. Admitting this, we shall find Rowe and Aubrey in harmony, and one great difficulty removed.

The early education of Shakspeare, as well as his parentage, is not ascertained: on this topic all the biographers and commentators have supplied us with conjectures and opinions. Chalmers, in his "Apology," is at once ingenious, intelligent, and learned on this subject. Rowe observes, and most of his followers repeat the same, that he "was bred for some time at a free school, where it is probable he acquired what Latin he was master of." They proceed to remark, that "on leaving school, he seems to have given entirely into that way of living which his father proposed to him." About the age of eighteen he married Anne Hathaway, daughter of a substantial yeoman, then residing at Shottory, a hamlet to Stratford. In the parish register we find that "Susanna, daughter of William Shakspeare, was baptised May 26, 1583." By the same record we learn that his wife produced him twins in 1584-5; as on the 2d of February in that year, the names of Judith and Hamnet are entered in the register. It must have been soon after this event that our poet visited the metropolis; but the cause of leaving his native place, as well as his object, connection, and prospects in London, are alike unknown. Rowe relates, and others have adopted the opinion, with some variation as to sentiment and inference, that, "falling into ill company," he was induced, "more than once," to assist his associates in stealing deer from a park belonging "to sir Thomas Lucy, of Charlote, near Stratford. For this he was prosecuted by that gentleman so severely," that he was first impelled to write a satirical ballad on him, and afterwards fly from his home to avoid arrest and imprisonment. This story, however, is not

entitled to full credence; for though our young poet might have associated with some idle youths, and have accompanied them to the neighbouring park, either for the sake of catching deer, or for some less *difficult* and *less hazardous* enterprise, yet the circumstance seems improbable, and comes in such "a questionable shape," that before it be admitted as historical evidence against an amiable man and super-eminent author, it should be supported by "confirmations strong as proofs of holy writ." Without resting on this circumstance, or crediting another absurd story, of his holding horses at the door of a theatre for his livelihood, we shall find a rational motive for his visiting London, and resorting to the theatre, by knowing that he had a relative and townsman already established there, and in some estimation. This was Thomas Green, "a celebrated comedian."

We now come to that era in the life of Shakspeare, when he began to write his immortal dramas, and to develop those powers which have rendered him the delight and wonder of successive ages. At the time of his becoming, in some degree, a public character, we naturally expected to find many anecdotes recorded of his literary history: but, strange to say, the same destitution of authentic incidents marks every stage of his life. Even the date at which his first play appeared is unknown; and the greatest uncertainty prevails with respect to the chronological order in which the whole series were written, exhibited, or published. As this subject was justly considered by Malone to be both curious and interesting, he has appropriated to its examination a long and laborious essay. Chalmers, however, in his "Supplemental Apology," and in a recent pamphlet, 1815, endeavours to controvert some of Malone's dates, and assigns them to other eras; as specified in the second column, below. Malone says, the "First Part of King Henry VI." published in 1589, and commonly attributed to Shakspeare, was not written by him, though it might receive some corrections from his pen at a subsequent period, in order to fit it for representation. The "Second Part of King Henry VI." this writer contends, ought therefore to be considered as Shakspeare's first dramatic piece; and he thinks that it might have been composed about the year 1591, but certainly not earlier than 1590. The other dramas are placed in the following order of time by him and by Mr. George Chalmers.

	According to Malone.	According to Chalmers.
The Third Part of Henry VI. } was written in - - -	1591	1595
A Midsummer Night's Dream - - -	1592	1598
Comedy of Errors - - -	1593	1591
Taming of the Shrew - - -	1594	1598
Love's Labour's Lost - - -	1594	1592
Two Gentlemen of Verona - - -	1595	1595

Othello - - - - -	1611	1614
The Tempest - - - - -	1612	1613
Twelfth Night - - - - -	1614	1613

Besides the above thirty-five plays, Shakspeare wrote some poetical pieces, which were at first published separately, viz. "Venus and Adonis," printed in 1593; "The Rape of Lucrece," 1594; "The Passionate Pilgrim," printed in 1599; "A Lover's Complaint," not dated; and a Collection of Sonnets, printed in 1609. The first and second of these poems were dedicated, as "the first heir of my invention," to Henry Wriothesley, earl of Southampton; who, according to sir William d'Avenant's statement, presented the poet with the sum of 1000*l.* to make some purchase. If this be a fact, it is honourable to the liberality and good taste of the nobleman, and shews that the "poor Warwickshire lad" met with a munificent patron in an early stage of his literary career. Other circumstances tend to prove that his merits were known to, and admired by, some illustrious personages. Queen Elizabeth, whose ear was perpetually assailed by fulsome panegyric, and who encouraged all sorts of silly shows, May-games, and buffooneries, was not insensible of Shakspeare's talents; for she commanded several of his plays to be acted before her; and having been much delighted with the character of Falstaff, as delineated in the first and second parts of "Henry the Fourth," recommended, or perhaps commanded, the bard to portray the fat knight in love. Hence originated "The Merry Wives of Windsor;" some incidents in which may have pleased the daughter of Henry VIII., although they are justly repulsive to modern taste and delicacy. King James I. also attended the representation of many of our author's plays. Sir William d'Avenant told Sheffield, duke of Buckingham, that the monarch wrote the poet "an amicable letter" with his own hand; probably to thank him for the compliment contained in the play of Macbeth.

Shakspeare, as already hinted, was an actor, as well as author of plays, and performed some of the characters in his own dramas. As late as the year 1603, only 13 years before his death, his name appears among the players of Ben Jonson's tragedy of Sejanus. Thus it is evident that he continued to perform many years; but of his histrionic merits we have no satisfactory evidence. Hence on this point there is much diversity of opinion; some contending that he was an excellent actor, and others that he was only equal to the personification of his own character of the ghost in Hamlet. Some passages in his own writings prove that he was well qualified to appreciate and to describe the essentials of good acting. See Hamlet's admirable advice to the players; the scene between Hamlet and his mother; and also the description of a tragedian in "King Richard III." Aubrey states that Shakspeare visited his native town periodically; but we do not learn when he finally returned home. From a document in the possession of Mr. R. B. Wheler, the historian of Stratford, it appears that he was in London in November, 1614. At that time Mr. Thomas

Green, a professional gentleman of that town, and a relative of Shakspeare's, visited the metropolis, to obtain an act of parliament, or to settle some business relating to the inclosure of an open field, in which our poet was a party concerned. His memorandums are;

"Rec. 16. No. 1614, at 4 o'clock afr. noon, a lre from Mr. Bayly & Mr. Alderman, [the bailiff and chief alderman of Stratford-upon-Avon] dated 12. No. 1614, touchyng the inclosure busyness. Jovis 17. No. [1614] my cosen Shakspeare comyng yesterdy to town, I went to see him how he did. He told me that they" [the parties wishing to inclose] "assured him they ment to inclose no further than to Gospel bush, & so upp straight (leavyng out pt. of the Dyngles to the field) to the gate in Clopton hedg & take in Salisbury's peece; & that they mean in April to svey. the land & then to gyve satisfaccion & not before: & he & Mr. Hall" [Shakspeare's son-in-law, probably present] "say they think yr. [there] will be nothyng done at all." It appears that Mr. Green, after his return to Stratford, made the following entry, which is partly illegible. "23. Dec. [1614] a Hall. lres. wryten, one to Mr. Manyring—another to Mr. Shakspeare, with almost all the company's hands to eyther. I also wrytte myself to my csn. [cousin] Shakspear, the coppys of all our . . . . . then also a note of the inconvenyences wold . . . . . by the inclosure." Another part of the memorandum states, that the town of Stratford was then "lying in the ashes of desolation."

We find that Shakspeare had purchased a house, called "New-place," at Stratford, about three years before his death, where he resided in the style and character of a private gentleman. Here he died on the anniversary of his birth-day, April 23, 1616, and was interred on the second day after his death, in the chancel of Stratford church, where a monument still remains to his memory. It is constructed partly of marble and partly of stone, and consists of a half-length bust of the deceased, with a cushion before him, placed under an ornamental canopy, between two columns of the Corinthian order, supporting an entablature. Attached to the latter is the Shakspeare arms and crest, sculptured in bold relief. Beneath the bust are the following lines:

Iudicio Pylivm, genio Socratem, arte Maronem,  
Terra tegit, popvlvs mæret, olympus habet.

Stay, passenger, why goest thou by so fast,  
Read, if thou canst, whom envious death hath plapt  
Within this monvment, Shakspeare: with whom  
Quick natvre dide; whose name doth deck ys tombe  
Far more than colte; sieh all yt he hath writt  
Leaves living art, bvt page to serve his witt.

Obiit Ano. Doi. 1616, Ætatis 53, die 23 Ap.

On a flat stone, covering the grave, is this curious inscription:

Good frend for Jefs' fake forbear,  
To digg the dvlt encloused heare;  
Blest be ye man yt spares these stones,  
And cvrll be he yt moves my bones.

The common tradition is, that the four last lines were written by Shakspeare himself; but this notion has perhaps originated solely from the use of the word "my," in the last line. The imprecation, says Mr. Malone, was probably suggested by an apprehension "that our author's remains might share the same fate with those of the rest of his countrymen, and be added to the immense pile of human bones deposited in the charnel-house at Stratford."

Mrs. Shakspeare, who survived her husband eight years, was buried between his grave and the north wall of the chancel, under a stone inlaid with brass, and inscribed thus: "Heere lyeth interred the bodye of Anne, wife of Mr. William Shakspeare, who depected. this life the 6th day of Avgvst, 1623, being of the age of 67 yeares."

Vbera, tv Mater, tv lac vitamq. dedilli,  
Væ mihi; pro tanto mvnere faxa dabo!  
Qvam Mallem, amoveat lapidem, bonvs angel'ore'  
Èxeat vt Christi Corpvs, imago tva,  
Sed nil vota valent, venias cito Christe refvrget,  
Clavfa licet tmvlo mater, et atra petet.

The family of Shakspeare, as already mentioned, consisted only of one son and two daughters. The son died in 1596; but both the daughters survived their father. The eldest, Susanna, married Dr. John Hall, a physician of Stratford, who is said to have obtained much reputation and practice. She brought her husband an only child, Elizabeth, who was married, first to Thomas Nashe, esq. and afterwards to sir John Barnard, of Abingdon, in Northamptonshire; but had no issue by either of them. Judith, Shakspeare's second daughter, married Thomas Quiney, a gentleman of good family, by whom she had three children; but as none of them reached their twentieth year, they left no posterity. Hence our poet's last descendant was lady Barnard, who was buried at Abingdon, Feb. 17, 1669-70. Dr. Hall, her father, died Nov. 25, 1635, and her mother July 11, 1649; and both were interred in Stratford church under flat stones, bearing inscriptions to their respective memories.

Shakspeare, by his *will*, yet extant in the office of the prerogative court in London, and bearing date the 25th day of March, 1616, made the following bequests.

To his daughter Judith he gave 150*l.* of lawful English money; one hundred to be paid in discharge of her marriage portion, within one year after his decease, and the remaining fifty upon her giving up, in favour of her elder sister, Susanna Hall, all her right in a copyhold tenement and appurtenances, parcel of the manor of Rowington. To the said Judith he also bequeathed 150*l.* more, if she, or any of her issue, were living three years from the date of his will; but in the contrary event, then he directed that 100*l.* of the sum should be paid to his niece, Elizabeth Hall, and the proceeds of the fifty to his sister, Joan, or Jone Hart, for life, with residue to her children. He further gave to the said Judith a broad silver gilt bowl.

To his sister Joan, besides the contingent bequest above-mentioned, he gave twenty pounds and all his wearing apparel; also the house in Stratford, in which she was to reside for her natural life, under the yearly rent of twelve pence. To her three sons, William Hart, — Hart, and Michael Hart, he gave five pounds a-piece; to be paid within one year after his decease. To his grand-daughter, Elizabeth Hall, he bequeathed all his plate, the silver bowl above excepted.

To the poor of Stratford he bequeathed ten pounds; to Mr. Thomas Combe, his sword; to Thomas Rullel five pounds; to Francis Collins, esq. thirteen pounds six shillings and eight-pence; to Hamlet (Hamnet) Sadler twenty-six shillings and eight-pence, to buy a ring; and a like sum, for the same purpose, to William Reynolds, gent., Anthony Nash, gent., John Hemyng, Richard Burbage, and Henry Cundell, his "fellows;" also twenty shillings in gold to his godson, William Walker.

To his daughter, Susanna Hall, he bequeathed New-place, with its appurtenances; two messuages or tenements, with their appurtenances, situated in Henley-street; also all his "barns, stables, orchards, gardens, lands, tenements, and

hereditaments whatsoever, situate, lying, and being, or to be had, received, perceived, or taken within the towns, hamlets, villages, fields, and grounds of Stratford-upon-Avon, Old Stratford, Bishopton, and Welcombe, or in any of them, in the said county of Warwick; and also all that messuage or tenement, with the appurtenances, wherein one John Robinson dwelleth, situated, lying, and being in the Blackfriars, London, near the Wardrobe; and all my other lands, tenements, and hereditaments whatsoever: to have and to hold all and singular the said premises, with their appurtenances, unto the said Susanna Hall, for and during the term of her natural life; and after her decease, to the first son of her body lawfully issuing, and to the heirs male of the body of the said first son, lawfully issuing; and for default of such issue, to the second son of her body lawfully issuing, and to the heirs male of the body of the said second son lawfully issuing;" and so forth, as to the third, fourth, fifth, sixth, and seventh sons of her body, and their heirs male: "and for default of such issue, the said premises to be and remain to my said niece Hall, and the heirs male of her body lawfully issuing; and for default of such issue, to my daughter Judith, and the heirs male of her body lawfully issuing; and for default of such issue, to the right heirs of me the said William Shakspeare."

To the said Susanna Hall and her husband, whom he appointed executors of his will, under the direction of Francis Collins and Thomas Ruffel, esqrs. he further bequeathed all the rest of his "goods, chattels, leases, plate, jewels, and household stuff whatsoever," after the payment of his debts, legacies, and funeral expences; with the exception of his "second best bed with the furniture," which constituted the only bequest he made to his wife, and that by insertion after the will was written out.

Among the mysteries connected with our poet's private life and actions is one, which has hitherto escaped the inveterate researches and countless opinions of his biographers and commentators. We have already seen, that his wife bore him three children in less than two years after marriage. In the Stratford register is an entry of "Thomas Greene, *alias Shakspeare*," in 1589-90, which excites some suspicion respecting the fidelity of our bard's wife: and it may be inferred from his will, that his lady could not have enjoyed much of his affection, to have been put off with only the bequest of a "second best bed:" besides, we do not hear of any other children by the poet.

The first collection of Shakspeare's plays was published in 1623, with the following title: "Mr. William Shakspeare's Comedies, Histories, and Tragedies. Published according to the true original copies. London, printed by Isaac Jaggard and Ed. Blount, 1623, folio." This volume was edited by John Hemyng and Henry Condell, and was dedicated to "the most noble and incomparable pair of brethren," William, earl of Pembroke, and Philip, earl of Montgomery. In the title page is a portrait, said to be a likeness of the author, with the engraver's name, "Martin Droeshout, sculpsit, London;" and on the opposite page are these lines by Ben Jonson, addressed to the reader:

"This figure that thou here seest put,  
It was for gentle Shakspeare cut,  
Wherein the graver had a strife  
With nature to outdoe the life:  
O, could he but have drawne his wit  
As well in brasse, as he hath hit  
His face; the print would then surpasse  
All that was ever writ in brasse.  
But, since he cannot, Reader, looke  
Not on his picture, but his Booke." B. I.

## SHAKSPEARE.

The above volume was carefully reprinted, in close imitation of the original, a few years back, by J. Wright, for Vernor and Hood, London. A second edition of Shakspeare's plays was published, in folio, in 1632, a third in 1664, and a fourth in 1685. These several impressions are usually denominated "ancient editions," because published within the first century after the death of the poet, and before any comments or elucidations were employed to expound the original text. Some of his dramas were published, in 4to., during his own life.

Of those editions which are distinguished by the title "modern," the earliest was published by Nicholas Rowe, in 1709, in 7 vols. 8vo. This was followed by an edition in 9 vols. 12mo. by the same author, in 1714; and to both were prefixed a biographical memoir of the illustrious bard. In 1725, Pope, who first introduced critical and emendatory notes, published his edition in 6 vols. 4to. with a preface, which Johnson characterizes as valuable alike for composition and justness of remark. A second edition by the same editor was published in 10 vols. 12mo. with additional notes and corrections, in 1728. The successor of Pope was Theobald, who produced a very elaborate edition in 7 vols. 8vo. in 1733; and a second, with corrections and additions, in 8 vols. 12mo. in 1740. Sir Thomas Hanmer next turned his attention to the illustration of Shakspeare, and in 1744 gave the world an edition of his plays in 6 vols. 4to. Warburton published his edition in 8 vols. 8vo. in 1747; from which time no critic attempted the task till the year 1765, when Dr. Johnson's first edition made its appearance in 8 vols. 8vo. It was preceded by an able and ingenious preface, in which the character of Shakspeare's writings are commented on in a powerful style of eloquence, but with a severity far removed from accuracy and justice. Indeed Johnson did not fully understand the varied merits of his author. In 1766, Steevens published the twenty "Old Plays," in 4 vols. 8vo. This was followed, in 1768, by an edition in 10 vols. crown 8vo. by Mr. Capell. Next came out, in 1771, a second and improved edition in 6 vols. 4to. by Sir Thomas Hanmer, which was succeeded by an edition in 10 vols. 8vo. in 1773, by Johnson and Steevens, conjointly. Of this last, a second edition was published in 1778; a third, revised and corrected by Reed, in 1785. In the year following was produced the first volume of the dramatic works of Shakspeare, with notes by Joseph Rann, A.M. which work was completed in 6 vols. 8vo. in 1794. In 1784 was published, in 1 vol. royal 8vo. an edition by Stockdale, with a very copious index of passages, by the Rev. Mr. Ayscough. Bell's edition appeared in 1788, in 20 vols. 18mo.; and in 1790 Malone's was ushered into the world in 10 vols. crown 8vo. In 1793, a fourth edition, "revised and augmented," in 15 vols. 8vo. was produced by Mr. Steevens. A fifth edition, in 21 vols. 8vo. was published in 1803, from the text and with the notes of Johnson, Steevens, and Reed; and another edition of 21 vols. with corrections, &c. appeared in 1813.

Many other impressions of our author's plays have been published by different bookfellers, in different sizes, and of various degrees of typographic merit. Most of them, however, are unauthenticated reprints; but many have the popular attraction of embellishments. The most splendid of this class was published by Boydell, in 9 vols. folio, embellished with 100 engravings, executed by and from artills of the first eminence. The same work was also printed in 4to. In 1805 was published an edition of Shakspeare's plays in 10 vols. 8vo., with a prefatory essay by Alexander Chalmers, F.S.A. and a print to each play from a design by Henry Fuseli, esq. R.A. The last edition of this kind

has just appeared in 7 vols. 18mo. with 230 engravings on wood, from the tasteful prefs of Whittingham.

Steevens estimated, at the time he published his notes on Shakspeare, that "not less than 35,000 copies of our author's works" had been then dispersed; and it may now be confidently said, that nearly 100,000 of them have been printed and sold.

From what has been already stated, it is evident that the writings of Shakspeare have progressively acquired considerable publicity; and that they now rank as chief, or in the first list, of British classics. This high celebrity is to be attributed to various secondary causes, as well as to their own intrinsic merits. To players, critics, biographers, and artists, a large portion of this popularity is to be ascribed; for had the plays been represented by Garrick, Kemble, &c. as originally published by Condell and Hemmynge, or reprinted verbatim from that text, the spectators to the one, and readers of the other, would have been comparatively limited. It is talent only that can properly represent and appreciate talent. The birth and productions of one man of brilliant genius, will stimulate the emulation, and call into action the full powers of a correlative mind. Hence the British theatrical hemisphere has been repeatedly illumined by the coruscations of Garrick, Henderson, Pritchard, Kemble, Siddons, Cooke, Young, and Kean; and these performers have derived no small portion of their justly acquired fame from the exquisite and powerful writings of the bard of Avon. Whilst the one may be considered as the creator of thought and inventor of character, the others have personified and given "local habitation" and existence to the poetical vision. The painter has also been usefully and honourably employed in delineating incidents, and portraying characters from the poet: while the engraver has translated these designs into a new language, and given them extensive circulation and permanent record.

The consummate acting of Garrick tended, in a great degree, not only to revive the fame of Shakspeare, but to augment and extend it. The peculiar powers of Betterton, and of his other dramatic predecessors, have not been sufficiently defined to enable us to estimate their real talents; but those of the English Roscius have been commented on and described by so many able critics, that we are certain they were of the most accomplished kind. He was therefore amply qualified to personify, and give life and effect to the characters of Macbeth, Hamlet, Lear, Richard the Third, Romeo, &c.; and by his exquisite representation of these histrionic personages, the public were additionally delighted and astonished with the amazing genius of the author. Since Garrick's time other actors have judiciously chosen some of Shakspeare's characters, as best calculated to shew their own talents; and as the most certain touchstone of passion. A Kemble and a Siddons have entwined their brows with never-fading laurel by diligently studying and successfully personating many of our poet's great characters. As the former has acquired a well-earned fame in portraying Macbeth, Lear, Coriolanus, Prospero, Cardinal Wolsey, Richard, Hamlet, and Othello; the latter has astonished and gratified many thousand spectators by her horrifying representation of lady Macbeth, her dignified playing of the queen in Henry VIII., and the queen in Hamlet; by her commanding powers in Portia; and in her pathetic eloquence of Desdemona. Cooke displayed the characters of Richard the Third, Iago, and Shylock, with great skill and excellence: and in the present day, Kean has personated these characters, with that of Richard II. and Hamlet, so as to command the approbation of the most acute and intelligent critics.

## SHAKSPEARE.

The number, variety, and versatility of commentaries that have been successively published on the text of Shakspeare's plays almost exceed credibility; and a foreigner, or stranger to the subject, would be more than astonished, were the whole brought in one mass before him. It is true, that many of them are unimportant and useless, but it is equally true, that several of his critical annotators have displayed much research, learning, and acuteness; and to such the philologist and poetical antiquary are much indebted. It was our intention to have given a concise account of these; because the whole constitute the Shakspearian library; and all may be regarded as satellites to the vast and resplendent poetical planet. The chief editors of his plays have been already noticed, as well as the respective eras of their different writings. Rowe was the first to add any thing to the original text, by prefixing a memoir of the author. This memoir has been reprinted with almost every succeeding edition, and without any alteration or comment, till Malone accompanied it with notes to his edition of 1790. Mr. Alexander Chalmers, in an edition of 1805, has prefixed a "Sketch of the Life of Shakspeare," in which he has adopted most of the statements of Rowe, with the additional and corrective remarks of Malone and Steevens. "The whole, however," he remarks, "is unsatisfactory. Shakspeare in his private character, in his friendships, in his amusements, in his closet, in his family, is no where before us."

The plays of Shakspeare are divided into three classes, and called in the first edition "comedies, histories, and tragedies." Each is of a distinct character; but in some of them there is a mixture of the three in one. "The Merry Wives of Windsor," "The Comedy of Errors," and "The Taming of the Shrew," are all comedies; the rest have something of both kinds. It is not easy to determine in which way of writing he most excelled. His Falstaff is universally allowed to be a master-piece: the character is always well sustained, though drawn out into three plays; and even the account of his death, given by his landlady, Mrs. Quickly, in the first act of Henry V. is as natural and diverting as any part of his life. "If there be any fault," says the critic, "in the draught he has made of this lewd old fellow, it is, that though he has made him a thief, a liar, and a coward, and, in short, every way vicious, yet he has given him so much wit, as to make him almost too agreeable; and I do not know whether some people have not, in remembrance of the amusement which he had formerly afforded them, been sorry to see his friend Hal use him so scurvily when he comes to the crown, in the end of the second part of Henry IV. Among other extravagancies in the 'Merry Wives of Windsor,' he has made him a deer-stealer, that he might have the opportunity of remembering his Warwickshire prosecutor under the name of Justice Shallow." The whole play is admirable, the humours are various and well opposed; the main design, which is to cure Ford of his unreasonable jealousy, is extremely well conducted.

Another of the characters which has been fixed on as one of Shakspeare's fine delineations, is that of Shylock, the Jew, in "The Merchant of Venice," in which there appears such a deadly spirit of revenge, such a savage fierceness, and such a bloody designation of cruelty and mischief, as cannot agree either with the style or character of comedy, though usually ranked as such. Taken altogether, it is perhaps one of the most finished of Shakspeare's pieces; the tale indeed is improbable in some of its parts; but taking the facts for granted, the story is beautifully written. There is something in the friendship of Antonio and Bassanio very great and generous. The whole

fourth act is extremely fine, but there are two passages that are universally known and applauded, the one is in praise of *mercy*, and the other is on the power of *music*.

The melancholy of Jaques in the comedy of "As you like it," is as singular and odd, as it is amusing, and if, according to the maxim of Horace,

"Difficile est proprie communia dicere,"

it will be a hard task for any one to go beyond him in the description of the several degrees and ages of a man's life. See the article AGE.

His images are indeed every where so lively, that the thing he would represent stands full before you, and you possess every part of it. Rowe mentions his image of Patience, in the person of a young woman in love, as one of the finest and most uncommon things ever written; it is as follows:

"————— She never told her love;  
But let concealment, like a worm i'th' bud,  
Feed on her damask cheek: she pin'd in thought,  
And sat like PATIENCE on a monument  
Smiling at grief."

The style of his comedy is, in general, natural to the characters, and easy in itself; and the wit most commonly sprightly and pleasing, except in those places where he runs into doggerel rhimes. But the greatness of this author's genius does no where so much appear, as where he gives his imagination the entire loose, and raises his fancy to a flight above mankind, and beyond the limits of the visible world. Such are his attempts in the Tempest, Midsummer Night's Dream, Macbeth, and Hamlet. Of these, the Tempest is thought by able critics to be the most perfect in its kind of any thing that Shakspeare has left behind him. His magic hath something in it very solemn, and very poetical: and that extravagant character of Caliban is extremely well sustained, and shews a wonderful invention in the author, who could strike out such a particular wild image, and it is certainly one of the finest that was ever exhibited to the human imagination. It has been said by able judges, that "Shakspeare had not only found out a new character in his Caliban, but had also devised and adapted a new manner of language for that character."

It is the same magic that raises the fairies in the Midsummer Night's Dream, the witches in Macbeth, and the ghost in Hamlet, with thoughts and language so proper to the parts they sustain, and so peculiar to the talent of this writer. "If," says the author whom we have so often quoted, "one undertook to examine the greatest part of his tragedies by those rules which are established by Aristotle, and taken from the model of the Grecian stage, it would be no difficult task to find a great many faults; but as Shakspeare lived under a kind of mere light of nature, and had never been made acquainted with the regularity of those written precepts, so it would be hard to judge him by a law of which he was ignorant. We are to consider him as a man, that lived in a state of almost universal licence and ignorance; there was no established judge, but every one took the liberty to write according to the dictates of his own fancy. When one considers, that there is not one play before him of a reputation good enough to entitle it to an appearance on the present stage, it cannot but be a matter of great wonder, that he should have advanced dramatic poetry as far as he did.

"It is now a received article of literary faith in England, that notwithstanding the faults and defects with which Shakspeare abounds, and which were chiefly those of his age, no dramatist in any country has displayed such intimate

intimate knowledge of the human heart; such extensive acquaintance with nature in its various forms, an imagination so powerful and poetical, and such a copiousness of moral sentiment expressed in the most forcible language." Dryden says, "he was a man, who, of all modern and, perhaps, ancient poets, had the largest and most comprehensive soul. All the images of nature were still present to him, and he drew them not laboriously, but luckily. When he describes any thing, you more than see it, you feel it too. He needed not the spectacles of books to read nature; he looked inwards, and found her there. I cannot say he is every where alike; were he so, I should do him injury to compare him with the greatest of mankind. He is many times flat and insipid: his comic wit degenerating into clenches, his serious swelling into bombast. But he is always great, when some great occasion is presented to him. No man can ever say, he ever had a fit subject for his wit, and did not then raise himself as high above the rest of the poets,

"Quantum lenta solent inter viburna cupressi."

Shakspeare, like most men of pre-eminent talents, is said to have been much assailed by the attacks of envious rivals, notwithstanding, that gentleness and good nature were the peculiar characteristics of his personal deportment. Among those who are said to have treated him with hostility was the celebrated Ben Jonson; but Dr. Farmer departs from the received opinions on this subject, and thinks that, though Jonson was arrogant of his scholarship, and publicly professed a rivalry of Shakspeare, he was in private his friend and associate.

Pope, in his preface, says, that Jonson "loved" Shakspeare "as well as honoured his memory; celebrates the honesty, openness, and frankness of his temper; and only distinguishes, as he reasonably ought, between the real merit of the author, and the silly and derogatory applauses of the players." Mr. Gilchrist, whose dramatic criticisms are generally profound and acute, has published a pamphlet, to prove that Jonson was never a harsh or an envious rival of Shakspeare; and that the popular opinion on this subject is founded in error. The following story respecting these two great dramatists is related by Rowe, and has been generally credited by subsequent biographers. "Mr. Jonson, who was at that time altogether unknown to the world, had offered one of his plays to the players, in order to have it acted; and the persons into whose hands it was put, after having turned it carelessly and superciliously over, were just upon returning it to him with an ill-natured answer, that it would be of no service to their company, when Shakspeare luckily cast his eye upon it, and found something so well in it, as to engage him first to read it through, and afterwards to recommend Mr. Jonson and his writings to the public."

The opposition or rivalry of Shakspeare and Jonson produced, as might naturally be expected, much contention, concerning their relative merits, between their respective friends and admirers; and it is not a little remarkable, that Jonson seems to have maintained a higher place in the estimation of the public in general than our poet, for more than a century after the death of the latter. Within that period Jonson's works are said to have passed through several editions, and to have been read with avidity, while Shakspeare's were comparatively neglected till the time of Rowe. This circumstance is in a great measure to be accounted for on the principle that classical literature and collegiate learning were regarded in those days as the chief criteria of merit. Accordingly Jonson's charge against Shakspeare was the

want of that species of knowledge; and upon his own proficiency in it, he arrogated to himself a superiority over him. That all classical scholars, however, did not sanction Jonson's pretensions, is certain; for among the greatest admirers of Shakspeare, was one of the most learned men of his age, the ever-memorable Hales. On one occasion, the latter, after listening in silence to a warm debate between Sir John Suckling and Jonson, is reported to have interposed by observing, "That if Shakspeare had not read the ancients, he had likewise not stolen any thing from them; and that if he (Jonson) would produce any one topic finely treated by any one of them, he would undertake to shew something on the same subject, at least as well written, by Shakspeare." A trial, it is added, being in consequence agreed to, judges were appointed to decide the dispute, who unanimously voted in favour of the English poet, after a candid examination and comparison of the passages produced by the contending parties.

In September, 1769, was celebrated the Shakspeare jubilee, at Stratford, under the direction of Garrick.

In pointing out the authorities for the preceding article, and noticing a few of the most interesting works that have been published in illustration of the writings of the "bard of Avon," we must conclude this essay, which may be deemed too prolix for some, and too brief by others. "Some Account of Shakspeare," by N. Rowe. Malone's, Steevens's, and Reed's "Prolegomena." "Remarks on the Life and Writings of W. Shakspeare," by John Britton, F.S.A. prefixed to Whittingham's edition of his plays, with wood-cuts, 1814. "A Guide to Stratford-upon-Avon," by R. B. Wheler, 12mo. 1814. "Critical, historical, and explanatory Notes on Shakspeare; with Emendations of the Text and Metre," by Zachary Grey, LL.D. two vols. 8vo. 1755. "Observations and Conjectures on some Passages of Shakspeare," by Thomas Tyrwhitt, 4to. 8vo. 1764. "An Essay on the Learning of Shakspeare," by the Rev. Dr. Rich. Farmer, 8vo. Three editions of this were published by the author, and it has, since 1789, been reprinted in different editions of Shakspeare's plays. "An Essay on the Writings and Genius of Shakspeare, compared with the Greek and French dramatic Poets; with some Remarks upon the Misrepresentations of Mons. de Voltaire," by Mrs. Montagu, 8vo. A sixth edition of this eloquent and interesting volume was printed in 1810. "Essays on Shakspeare's Dramatic Characters," by W. Richardson, M.D. 8vo. 1812, are replete with judicious criticism and apposite comment. "Remarks, critical and illustrative, on the Text and Notes of the last Edition of Shakspeare," (1778,) by Mr. Ritson, 8vo. 1783. "An Inquiry into the Authenticity of certain miscellaneous Papers, published Dec. 24, 1795," &c. by Edmond Malone, 4to. 8vo. 1796. This inquiry called forth two vols. called "An Apology for the Believers in the Shakspeare Papers," by G. Chalmers, 8vo. 1797: and a "Supplemental Apology for the Believers, &c." by the same author, 8vo. 1799. "Illustrations of Shakspeare, and of ancient Manners, &c." by Francis Douce, 2 vols. 8vo. 1807, is a work of very considerable merit.

Shakspeare was fond of music, and not wholly ignorant of the art. He not only frequently introduces *masques for music* in his plays, but singing in almost all his fourteen comedies; and even in most of his tragedies, where this wonderful and exquisite dramatist has manifested the same predilection for music as poetry.

In the "Tempest," the use that he has made of it is admirable, as well as the description of its effects. Act i. sc. 5. Ariel, invisible, playing and singing to Ferdinand, says,

# SHAKSPEARE.

“ Where should this music be, i' th' air or earth?  
It sounds no more: and sure it waits upon  
Some god o' th' island.”

And afterwards:

“ This is no mortal business, nor no sound  
That the earth owns: I hear it now above me.”

Indeed, the serious part of this most fanciful play is very fortunately calculated for an opera. Shadwell, in the last century, made one of it, in the manner of what were then called operas on our stage. It has been performed of late years more as a musical masque, than opera or play, at Drury-lane, to the music of the late Mr. T. Linley, as it used to be to that of Dr. Arne, and others. The songs in this play, Dr. Wilson, who reset and published two of them, tells us, in his “Court Ayres, or Ballads,” published at Oxford, 1660, that “Full fathom five,” and “Where the bee sucks,” had been first set by Robert Johnson, a composer contemporary with Shakspeare.

Act ii. sc. 1. “Enter Ariel playing solemn music.” We never could understand this indication: no music seems to be heard by the characters on the stage, nor do they take any notice of it through the whole scene. Afterwards, when with music and a song he acquaints Gonzalo of the danger he is in, his mission has meaning. “While you here do snoring lie,” &c.

Even Caliban talks well about music:

“ — the isle is full of noises,  
Sounds and sweet airs, that give delight and hurt not.”

Ariel never appears or is employed without music, which is sweetly described, and introduced with perfect propriety. Prospero calls for medicinal music:

“ A solemn air, and the best comforter  
To an unsettled fancy, cure thy brains.”

“Midsummer Night's Dream.”

Act ii. sc. 5. “Come now a *roundel*, and a fairy song.” If, as Dr. Gray says, a *roundel* is “a dance in a ring,” a *roundelay* was the song and tune to such dance; as *ballad*, from *ballata*, Italian; to *roundelay*, from *rondelet*, old French, *rondeau*, modern.

The ideas and language of fairyism are wonderfully imagined and supported in this play; and the use alligned to music happy and fertile.

Act iv. sc. 1. “Rural music, tongs, &c.” Poker and tongs, marrow-bones and cleavers, salt-box, hurdy-gurdy, &c. are the old national instruments of music on our island.

Queen. “Music, ho! music: such as charmeth sleep.”

*Still* music, meaning such soft and gentle music as tranquillizes, soothes, and lulls to music.

Act v. sc. 1. In the list of sports ready for the nuptial feast of Theseus, is “the battle with the Centaurs; to be sung by an Athenian eunuch to the harp.” This seems to imply a more ancient practice of castration for the voice than can be found in opera annals.

Speaking of Quince, in the clown's prologue, Hippolita says, “indeed, he hath play'd on his prologue, like a child on a recorder; a sound, but not in government.”

Two songs alluded to in the last scene of this play are lost.

Oberon. “And this ditty after me  
Sing and dance it trippingly.”

Queen. “First rehearse this song by rote,  
To each word a warbling note;  
Hand in hand, with fairy grace,  
Will we sing, and bless this place.”

“Two Gentlemen of Verona.”

Though this comedy furnishes fewer occasions for music than the two preceding dramas, yet musicians are employed in it as well as musical allusions. As Ben Jonson, in his masque of “Cynthia's Revels,” speaks of the gamut or syllables of solmifation, *ut, re, mi, fa, sol, la*, which psalm-singers had made well known to his audience; so Shakspeare, in this play, act i. sc. 3. introduces all the musical terms then in use: as, a *tune*, a *note*, a *light*, a *heavy tune*, *burden*, *melodious*, to *reach high*, *keep in tune*, *sing out*, *too sharp*, *too flat*, *concord*, *barsh descant*, *the mean base*, &c.

Act iv. sc. last, there is a laboured description of the powers of poetry and music; Orpheus's lute, *concert*, spelt as now:

“ — to their instruments  
Tune a deploring *dump*,” —

or lament (*lamentatione*), sung by a wretched and forrowing lover in the *dumps*.

Sc. 2. A *serenata*, or *notturmo*, is introduced:

“ — now must I to her window,  
And give some *evening* music to her ear.”

Enter Musicians.

“ — now, gentlemen,  
Let's tune, and to it lustily.”

Song. “Who is Sylvia? what is she?” &c.

“Measure for Measure.”

Though this play has less music in it than the three preceding, yet at the beginning of act iv. a song, from his own *Passionate Pilgrim*: “Take, oh, take those lips away,” is sung to Mariana by a boy, who is sent away on the arrival of the duke, in the character of a friar; when apologizing for the seeming levity of listening to music, she says:

“I cry you mercy, sir, and well could wish  
You had not found me here so musical.”

To which the duke answers:

“'Tis good; though music oft hath such a charm,  
To make bad good; and good provoke to harm.”

This is a heavy charge, which it would not have been easy for Shakspeare to substantiate, and does not very well agree with what he says in the “*Tempest*,” of the *innocuous* efficacy of music. “Sounds and sweet airs, that give delight, and *hurt not*.” Music may be applied to licentious poetry; but the poetry then corrupts the music, not the music the poetry. It has often regulated the movements of lascivious dances; but such airs heard, for the first time, without the song or dance, could convey no impure ideas to an innocent imagination; so that Montetquien's assertion is still in force: that “music is the only one of all the arts, which does not corrupt the mind.”

“Merchant of Venice.”

Act ii. sc. 1. A flourish of cornets when the Moorish prince comes in.

Act ii. sc. 6. “The vile squeaking of the wry-neck'd  
fife.”

Act

Act iii. sc. 2. " Let music found, while he doth make  
his choice ;  
Then, if he lose, he makes a swan-like  
end,  
Fading in music.  
—— he may win ;  
And what is music then ? then music is  
As are those dulcet sounds at break of  
day,  
That creep into the dreaming bride-  
groom's ear,  
And summon him to marriage."

Music within.

A song while Bassanio examines the caskets :

" Tell me where is fancy bred," &c.

The passages in the fifth act of this interesting play are beautiful, numerous, and celebrated :

" And bring your music forth into the air," &c.

" —— soft stillness and the night

Become the touches of sweet harmony."

Jessica. " I am never merry when I hear sweet music." This is the initial of a well-known, and now *proverbial*, eulogium on modulated sound : " The man that has no music in his soul," &c.

" As you like it."

Act ii. sc. 1. A song :

" Under the green-wood tree," &c.

Remarks on music by Jacques. Then another song :

" Blow, blow, thou winter's wind."

Music. Song : " What shall he have that kill'd the deer."

Song : " 'Twas a lover and his lass."

Still music. Song : " Then is there mirth in heav'n."

Another song : " Wedding is great Juno's crown."

" Love's Labour's lost."

Act iii. Armado. " Warble child ; make passionate my sense of hearing."

This is a most beautiful and comprehensive request : none of the fine arts can subsist, or give rapture, without *passion*. Hence mediocrity is more intolerable in them than in other inventions. Music without passion is as monotonous as the tolling of a bell.

But no song is printed : though the author tells us there is *singing*. Dr. Johnson says, " here is apparently a song lost."

Music as for a masquerade.

Songs for spring and autumn :

" When daisies pied."—And, " When icicles hang on the wall."

" Winter's Tale."

Two nonfencical songs, by the rogue Autolychus :

" When daffodils begin to peere."—" Jog on, jog on, the footpath way."

" He's main musical." This Autolychus is the true ancient minstrel, as described in the old Fabliaux. See Gen. Hill. Mus. vol. ii. p. 208.

A three-part catch, ready planned by the poet, and another pedlar's song ; " Will you buy any tape?"

" Twelfth Night."

Act i. sc. 1. This play opens with a beautiful eulogium on music :

" If music be the food of love, play on," &c.

The use of *Evirati*, in the same manner as at present, seems to have been well known at this time (about 1600). For Viola says :

" —— I'll serve the duke ;  
Thou shalt present me as a *eunuch* to him,  
It may be worth thy pains, for I can sing,  
And speak to him in many sorts of music,  
That will allow me very worth his service."

And the duke's sensibility to the power of music is disclosed in the first interview, when he says to Viola :

" —— thy small pipe  
Is as the maiden's organ, shrill and sound,  
And all its semblative—a woman's part.  
I know thy constellation is right apt  
For this affair ;"——

supposing her to be a eunuch.

Act ii. sc. 3. The clown is asked for a love-song, and sings :

" O mistress mine, where are you roaming?" &c. And  
" What is love ; 'tis not hereafter," &c.

Ibid. They sing a catch, beginning,

" Hold thy peace."

Sc. 4. Scraps of songs and catches are roared out by sir Toby, sir Andrew, and clown, as " Three merry men be we."—" Tilly, valley, lady !"—" There dwelt a man in Babylon, lady, lady."—" O the twelfth day of December."—" Farewel, dear heart, since I must needs be gone."—" His eyes do shew his days are almost done."—" Shall I bid him go ? what, an' if you do?"—" Shall I bid him go, and spare not ? O no, no, no, you dare not." All these, probably, were well known in Shakspeare's time.

Sc. 5. The duke, who is as constant in his passion for music, as for Olivia, says :

" —— give me some music now—  
Now, good Cesario, but that piece of song,  
That old and antique song, we heard last night ;  
Methought, it did revive my passion much ;  
More than light airs, and recollected terms  
Of these most brisk and giddy-paced times :  
—— how dost thou like this tune ?—  
It gives a very echo to the feat  
Where love is thron'd."

Ibid. " —— the song we had last night—

—— it is old and plain ;

The spinsters and the knitters in the sun,  
And the free maids that weave their thread with  
bones,

Do ute to chaunt it : it is silly foolery,  
And dallies with the innocence of love,  
Like the old age."

Song : " Come away, come away, death."

Act iv. sc. 4. The clown, as elsewhere, is much addicted to singing. Song, by the clown :

" When that I was a little tiny boy," &c.  
serves as an epilogue to this entertaining play.

# SHAKSPEARE.

In "The Taming of the Shrew," no other use is made of music than to introduce minstrels at the wedding, and disguise Hortensio in the character of a man *well seen in music*, to facilitate his admission to the presence and courtship of Bianca; an expedient, however, which was unsuccessful.

More fragments of old ballads are here quoted than in any other of Shakspeare's plays; though, as Dr. Warburton said, "he seemed to bear the ballad-makers a very particular grudge, and often ridicules them with exquisite humour."

In "The Comedy of Errors," music has no admission or concern.

"Much ado about Nothing."

Music at the masquerade, act ii. sc. 2. And in Benedict's dainty description of such an all-accomplished woman as could ever incline him to wed, he adds to her qualifications, *music*: "—of good discourse, an *excellent musician*, and her hair of what colour it shall please God." Sc. 8.

Act ii. sc. 9. The song, "Sigh no more, ladies, sigh no more," is introduced by several reflections on music, and the affectation of fingers. Baltazar, the musician and servant to Don Pedro, was perhaps thus named from the celebrated Baltazarini, called "De Beaujoyeaux," an Italian performer on the violin, who was in the highest fame and favour at the court of Henry III. of France, 1577. In the last act, sc. 8, the epitaph and song are beautiful, and well calculated for music.

"All's Well that ends Well."

Act i. sc. 5. Flourish of cornets for the king of France's entrance and exit.

Act iii. sc. 8. A tucket afar off. *Ibid.* A march afar off.

Act v. sc. 3. Sound trumpets.

Historical plays. "King John."

No music but trumpets and the din of war.

"King Richard II."

Act i. sc. 4. Military instruments are admirably described:

"—rous'd up with boist'rous untun'd drums,  
And harsh resounding trumpets dreadful bray."

*Ibid.* Mowbray, duke of Norfolk, on being ordered into banishment, says:

"My native English, now I must forego;  
And now my tongue's use is to me no more,  
Than an unstringed viol, or a harp;  
Or, like a cunning instrument cas'd up,  
Or being open, put into his hands  
That knows no touch to tune the harmony."

Act ii. sc. 1. "—the tongues of dying men  
Inforce attention, like deep harmony:  
—more are men's ends mark'd, than their lives  
before;  
The setting sun, and *music in the clofe*,  
As the last taste of sweets, is sweetest last——"

*Ibid.* sc. 3. Speaking of John of Gaunt's death:

"——all is said,  
His tongue is now a stringless instrument."

Act v. sc. 10. Richard, in his prison, says:

"——Music do I hear?  
Ha, ha! keep time: how fow'r sweet music is,  
Where time is broke, and no proportion kept?"

Here he plays on musical terms for several lines.

All instruments played with the bow, in Shakspeare's time, were fretted, except violins.

In "The Taming of the Shrew," act ii. sc. 3, he could not resist the temptation of quibbling on the term *fret*.

"Frets call you them? quoth she: I'll fume with them."

"——then call'd me rascal, fidler,  
And twangling *Jack*;"

alluding to a famous street musician of the time.

"First Part of Henry IV."

Act i. sc. 2. Falstaff says he's as melancholy as the "drone of a Lincolnshire bagpipe."

Act ii. sc. 3. "An I have not ballads made on you all, and sung to filthy tunes, let a cup of sack be my poison."

Act iii. sc. 3. "——thy tongue  
Makes Welch as sweet as ditties highly penn'd,  
Sung by a fair queen in a summer's bower,  
With *ravishing division* to her lute."

"Second Part of Henry IV."

Induction. "——Rumour is a pipe,  
Blown by fumes, jealousies, conjectures;  
And of so easy and so plain a stop,  
That the blunt monster with uncounted heads,  
The still discordant wavering multitude,  
Can play upon it."

We advanced no farther in hunting through the pleasant wilds of Shakspeare; but in dipping accidentally, the following passages struck us as worthy of notice.

"Henry V." Act i. sc. 2. There is a manifest allusion to the different parts of music.

"For government, though *high*, and *low*, and *lower*,  
Put into *parts*, doth keep in one *consent*,  
Congreering in a full and natural close,  
Like music."

In "Othello," act iv. sc. 13. Desdemona says:

"My mother had a maid, called Barbara;  
She was in love; and he, the lov'd, prov'd mad (*false*),  
And did forsake her: she had a song of *willow*,  
An old thing 'twas, but it express'd her fortune,  
And she died singing it. That song, to-night,  
Will not go from my mind; I've much ado,  
Not to go hang my head all o' one side,  
And sing it like poor Barbara."

"King Lear," act i. sc. 7. "O, these eclipses portend these divisions! *fa, sol, la, mi*."

None of the commentators have hitherto been sufficiently skilled in music to see the meaning of these syllables in solmisation, which imply a series of sounds so unnatural, that ancient musicians prohibited their use. "Mi contra fa est diabolus." Shakspeare, however, shews by the context, that he was well acquainted with the property of the musical intervals contained in the tritonus, or sharp 4th, which consisting of three tones, without the intervention of a semitone, is extremely difficult to sing, and disagreeable when

when sung, if *mi*, or *fa*, is the last note of the phrase or passage.

**SHAKSPEARE'S Cliff**, or *High Cliff*, in *Geography*, a lofty cliff on the E. coast of England, in the county of Kent; so called from the beautiful description of it given by that poet in the tragedy of King Lear; 2 miles S. of Dover.

**SHAKY**, or **SHAKEN**, a natural defect in timber when it is full of splits or clefts, and will not bear the fastening, or when sawn into plank the caulking.

**SHAL**, in *Geography*, a district of Persia, in Balouchistan, the country of the Balouches, which is considered by some as a province distinct from Mekran (the ancient Gedrosia), and which commences at Koohinee (the hilly road), 25 miles N.E. of Bayla, or in N. lat.  $26^{\circ} 35'$ , and extends to Noohky, 79 miles N.W. of Kelat, or in N. lat.  $30^{\circ}$ . This country is a confused mass of mountains, through which the road generally leads in water-courses. Flocks of sheep and cattle abound in every part of this country, and it also produces great quantities of wheat. It is divided into the two mountainous provinces of Jhalawan and Sarawan, the low country of Cutch Gandava to the E., and the provinces of Zuhree and Anund Dijel; and to these may be added the small districts of Shal and Mullung, lying N. of Kelat. Shalawan is the most southern province of Balouchistan, and Sarawan (which see) is the most northern province. Cutch Gandava, situated at the bottom of the mountain lying S.E. of Kelat, is about 150 miles long, and 40 or 50 broad. Its soil is rich, black, and loamy, and produces every species of grain, as well as cotton, indigo, madder, &c. Cutch Gandava exports great quantities of grain to the sea-ports of Curachee and Sonmeany, whence it is shipped to Muscat, the coast of Mekran, &c. Anund Dijel lies N. of Cutch Gandava: its climate is good, the soil excellent, and the productions abundant; so that the khan of Kelat derives a large revenue from this small district. Shal and Mullung are smaller than Anund Dijel, but they are remarkable for their fruits, which are excellent and cheap. The climate is warmer than that of Kelat; the soil is more sandy; but the grain and other products are the same. (See ZUHREE.) The capital of Balouchistan is Kelat, a town surrounded by a mud-wall, and containing 4000 houses, and about 7000 inhabitants, of whom about 500 are Hindoos. The bazar of Kelat is well supplied, and the town appears opulent, being frequented by merchants, and carrying on a considerable trade. N. lat.  $29^{\circ} 6'$ . E. long.  $67^{\circ} 57'$ .

**SHALBERG**, a mountain of Switzerland; 4 miles N. of Sargans.

**SHALBERIS**, a circle of Hindoostan, bounded on the N. by Goragot and Bettooriah, on the E. and S. by Bettooriah, and on the W. by Bettooriah and Dinagepour; about 18 miles from N. to S. and nearly as much from E. to W. The chief town seems to be Cartee.

**SHALDEAH**, a town of Hindoostan, in Bahar; 7 miles S.W. of Rotasgur.

**SHALE**, in *Natural History*, a variety of schistose clay: the first variety is denominated flint clay, the schiefer Thon of Werner. (See CLAY.) The second variety is bituminous slate, the brand schiefer of Werner, of a brownish-black, or blackish-brown, colour, appearing like bad coal; it is found in considerable stratified masses; lustre, 0 or 1; transparency, 0; fracture flaty; fragments tabular: hardness, 5; sp. gr. about 2,000; streak somewhat glossy; effervescing, though very slowly, with the mineral acids: feeling rather greasy; placed on burning coals, it burns with a weak flame and sulphureous smell, the residuum being light-

grey; it seems to differ from the former variety, in containing bitumen. Kirwan. See TABULAR SPAR.

The acid emitted from shale, during its calcination, uniting itself to the argillaceous earth of the shale, forms alum. About a hundred and twenty tons of calcined shale will make one ton of alum. The shale, after being calcined, is steeped in water, by which means the alum, which is formed during the calcination of the shale, is dissolved: this dissolved alum undergoes various operations, before it is formed into the alum of the shops. Watson's Chem. Eff. vol. ii. p. 315. See ALUM.

This kind of slate forms large strata in Derbyshire; and that which lies near the surface of the earth is of a softer and more shivery texture than that which lies deeper. It is also found in large strata, generally above the coal, in most coal counties of this kingdom. Dr. Short informs us, that the shale wastes the lead ore near it, by its strong acid; and that it corrodes and destroys all minerals near it, except iron or coal, of whose vitriol it partakes. See SLATE.

**SHALG**, in *Geography*, a town of Turkellan; 10 miles S. of Turkellan.

**SHALLOP**, **SHALLOOP**, or *Sloop*, is a small light vessel, with only a small main-mast, and fore-mast, and lug-sails, to hale up, and let down, on occasion.

Shallops are commonly good failers, and are therefore often used as tenders upon men of war.

The French shallop is a large-decked sloop of burden, used in Holland and Flanders, having one mast, carrying a gaff-maintail. On the fore-side of the mast, above the gaff, is a short spar projecting forwards; to which is bent a long narrow sail, the tack of which is made fast to the stem, and the sheet to the side near the shrouds. On the bowsprit are set two or three jibs, and a small mast is often fixed abaft that carries a mizen.

**SHALLOT**, in *Gardening*, the common name of a very useful culinary plant. See ALLIUM.

To what has been said under the above head, it may here be necessary to add some improvements, which have since been made, in the culture of these small bulbous roots. As the habits of growth in roots of this nature differ greatly in the different sorts, some requiring to be nearly or quite on the surface of the ground, while others stand in need of being a considerable depth below it, which has not been well attended to in the garden culture of such roots; it may be readily supposed that these have considerable influence and effect on the growth of such root crops. In consequence of finding that crops of this root generally became mouldy and perished, and that they were usually planted, from the directions of garden cultivators, at the depth of two or three inches from the surface; the injury, failure, and destruction of such crops, were naturally ascribed to this cause. A few bulbs or bunches of this root were consequently divided, as far as possible, into single buds or bulbs, and planted upon or rather above the surface of the ground, some very rich soil being placed underneath them, and the mould on each side raised to support them, until they became firmly rooted. This mould was then removed by means of a hoe, and the use of the watering-pot, and the bulbs of course left wholly out of the ground. The growth of the plants had now so near a resemblance to that of the common onion, as not readily to be distinguished from it, until their irregularity of form, the consequence of the numerous germs within each bulb, became evident. The forms of the bulbs, however, continued constantly different from all those raised in the ordinary method, being much more broad, but of less length. The crop was a great deal better in quality, and at the same time much

more abundant in quantity. It may consequently not be unworthy of the gardener's attention. See the Transactions of the Horticultural Society of London, vol. ii. p. 97.

**SHALLOT Creek**, in *Geography*, a river of North Carolina, which runs into the Atlantic, N. lat.  $33^{\circ} 53'$ . W. long.  $78^{\circ} 28'$ .

**SHALLOW**. See **SHOAL**.

**SHALTOCH CAIRN**, in *Geography*, a mountain of Scotland, in Ayrshire; 12 miles E. of Girvan.

**SHAM, EL.** See **DAMASCUS**.

**SHAMADE**, in *War*. See **CHAMADE**.

**SHAMALAPALEAM**, in *Geography*, a town of Hindoostan, in Coimbatore; 15 miles N.E. of Coimbatore.

**SHAMARASHUP**, a town of Hindoostan, in Coimbatore; 18 miles S.W. of Errood.

**SHAMBE**, a river of West Florida, which runs into Pensacola bay.

**SHAMBLE**, or **SHAMMEL**, in *Mining*, a term used to express a sort of nich, or landing place, left at certain distances in the adits of mines, and formed by a stage of boards. The method of digging the tin-mines in Devonshire, and some parts of Cornwall, is thus; they sink their way in such a breadth as is sufficient for them to stand and work, and at every fathom they leave a square place vacant, to which the ore is to be thrown up with shovels as it is dug. This they do from cast to cast; that is, as far as a man can conveniently throw up the ore with his shovel. Thus the ore, as it is dug by the beammen, is thrown up by the shovellers, who follow them from shamble to shamble, till it comes to the top of the mine. This, however, is but an inconvenient way, and the use of these shambls is generally supplied by a winder at the opening of the mine, which manages two buckets, the one of which is sent down empty, while the other is sent up full; and one man employed below to load, and another to empty. Phil. Trans. N<sup>o</sup> 60. See **MINING**.

**SHAMBLES**, or **SHINGLES**, in *Geography*, a bank of sand in the English Channel, near the coast of Dorsetshire, about four miles E. by S. from Portland Bill, with 14 feet at low water.

**SHAMBRIER**, in the *Manege*, is a long thong of leather, made fast to the end of a cane, in order to animate a horse, and punish him, if he refuses to obey the rider.

**SHAMBYPATAM**, in *Geography*, a town of Hindoostan, in the Carnatic; 36 miles S. of Tanjore.

**SHAMDARA**, a town of Assam, on the Burhampooter; 65 miles N.W. of Gerghouge.

**SHAME**, in *Ethics*. See **PASSION**.

**SHAMERAN**, in *Geography*, a town of Curdistan; 18 miles S. of Sherezur.

**SHAMMY**, **CHAMMY**, or *Chamois*, a kind of leather, either dressed in oil, or tanned; much esteemed for its softness, pliancy, &c.

It is prepared from the skin of the chamois, or shamois, a kind of rupicapra, or wild goat, called also *isard*, inhabiting the mountains of Dauphiny, Savoy, Piedmont, and the Pyrenées. See **CHAMOIS**.

Besides the softness and warmth of the leather, it has the faculty of bearing soap without damage; which renders it very useful on many accounts.

In France, &c. some wear the skin raw, without any preparation. Shammy leather is used for the purifying of mercury; which is done by passing it through the pores of the skin, which are very close.

The true chamois leather is counterfeited with common goat, kid, and even with sheep-skins; the practice of which makes a particular profession, called by the French *chamois-*

*sure*. The last, though the least esteemed, is yet so popular, and such vast quantities of it are prepared, especially about Orleans, Marleilles, and Toulouise, that it may not be amiss to give the method of preparation.

*Manner of Shamoying, or of preparing Sheep, Goat, or Kid-skins in Oil, in imitation of Shammy.*—The skins, being washed, drained, and smeared over with quick-lime on the fleshy side, are folded in two lengthwise, the wool outwards, and laid in heaps, and so left to ferment eight days; or, if they had been left to dry after slaying, then fifteen days.

Then they are washed out, drained, and half dried; laid on a wooden leg, or horse, the wool stripped off with a round staff for that purpose, and laid in a weak pit, the lime of which had been used before, and has lost the greatest part of its force.

After twenty-four hours they are taken out, and left to drain twenty-four more; they are then put in another stronger pit. This done, they are taken out, drained, and put in again, by turns; which begins to dispose them to take oil; and this practice they continue for six weeks in summer, or three months in winter: at the end of which they are washed out, laid on the wooden leg, and the surface of the skin on the wool-side peeled off, to render them the softer; then made into parcels, steeped a night in the river, in winter more, stretched six or seven over one another, on the wooden leg, and the knife passed strongly on the flesh-side, to take off any thing superfluous, and render the skin smooth.

Then they are steeped, as before, in the river, and the same operation is repeated on the wool-side; they are then thrown into a tub of water, with bran in it, which is brewed among the skins till the greatest part sticks to them, and then separated into distinct tubs, till they swell, and rise of themselves above the water.

By this means the remains of the lime are cleared out; they are then wrung out, hung up to dry on ropes, and sent to the mill, with the quantity of oil necessary to scour them: the best oil is that of stock-fish.

Here they are first thrown in bundles into the river, for twelve hours, then laid in the mill-trough, and filled without oil till they be well softened; then oiled with the hand, one by one, and thus formed into parcels of four skins each; which are milled and dried on cords a second time; then a third; and then oiled again, and dried.

This process is repeated as often as necessity requires; when done, if there be any moisture remaining, they are dried in a stove, and made up into parcels wrapped up in wool: after some time they are opened to the air, but wrapped up again as before, till such time as the oil seems to have lost all its force, which it ordinarily does in twenty-four hours.

The skins are then returned from the mill to the chamoiser, to be scoured; which is done by putting them in a lixivium of wood-ashes, working and beating them in it with poles, and leaving them to steep, till the ley hath had its effect; then they are wrung out, steeped in another lixivium, wrung again; and this is repeated till all the grease and oil be purged out. When this is done, they are half dried, and passed over a sharp-edged iron instrument, placed perpendicular in a block, which opens, softens, and makes them gentle; lastly, they are thoroughly dried, and passed over the same instrument again; which finishes the preparation, and leaves them in form of shammy.

Kid and goat-skins are shamoyed in the same manner as those of sheep, excepting that the hair is taken off without the use of any lime; and that when brought from the

the mill, they undergo a particular preparation called *ramalling*; the most delicate and difficult of all the others. It consists in this, that, as soon as brought from the mill, they are steeped in a fit lixivium, taken out, stretched on a round wooden leg, and the hair is scraped off with the knife; this makes them smooth, and, in working, to cast a kind of fine knap. The difficulty is in scraping them evenly.

**SHAMOKIN**, in *Geography*, a town of Pennsylvania, in Northumberland county, containing 2027 inhabitants.

**SHAMOKIN Creek**, a river of Pennsylvania, which runs into the Susquehanna. N. lat. 40° 51'. W. long. 76° 53'.

**SHAMZANGI**, a town of Persia, in the province of Laristan.

**SHANCORI**, a town of Persian Armenia; 12 miles W.N.W. of Kanja.

**SHANDECAN**, BIG, a town of New York, in the county of Ulster, 14 miles N.W. of Kingston.

**SHANDECAN**, Little, a town in the same county; 12 miles N.W. of Kingston.

**SHANDYMUNGULUM**, a town of Hindoostan, in Baramaul; 8 miles E. of Namacul.

**SHANEDI**, a town of Nubia, on the right bank of the Nile; 45 miles S.W. of Nubia.

**SHANGOLDEN**, a small post-town of Ireland, in the county of Limerick; 115 miles W.S.W. from Dublin.

**SHANGRA**, a country of Africa, W. of Mocaranga.

**SHANGRAPOY**, a town of Hindoostan, in Marawar; 20 miles S.S.E. of Trumian.

**SHANK**, in *Conchology*, the Sanscrit name of that species of shell, which gives its name in Europe to this branch of natural history. French and other foreign writers spell the word *chank*. The easy substitution of a hard for a soft initial, has led to a supposition that conch may by early writers have been taken from the same source as shank, or even derived from it. The shank, or chank, or conch, is the large buccinum, and is often seen beautifully coloured like a pheasant's breast. With the Hindoos, the shank is an object of mystical reverence. It is seen in one of the four hands of their deity VISVANT, and is one of his commonest attributes. Images and pictures of him are indeed distinguished more by this than by any other mark. It has of course a fabulous or mythological origin; and we accordingly find it among the "fourteen gems" that were recovered from the ocean, after a general deluge, as related under the article KURMAVATARA of this work, where the shank is said to be "a shell conferring victory on any one who should find it." In the distribution of the precious articles, the shell seems to have fallen to the share of Vishnu.

Shells, as arming implements, were much used in early Indian wars, as trumpets and drums are with us. In the terrible civil wars between the Pandus, and their kinsmen the Kurus, as Homericly described in the Mahabarat, Krishna used a shell named Panchajanya, obtained in the manner related under our article KASYA, from a feather named *Sankafura*, which see. Each chief in the wars alluded to bore a shell, to which, like the swords of our chivalrous knights, distinct and significant names are given. In the portion of the Mahabarat translated by Mr. Wilkins, called Bhagavat Gita, the following passage occurs. "The ancient chief, and brother of the grand sire of the Kurus, then shouting with a voice like a roaring lion, blew his shell to raise the spirit of the Kuru chief; and instantly innumerable shells, and other warlike instruments, resounded on all sides,—the clangour was excessive. Krishna and Arjun, standing in a splendid chariot drawn by white horses,

founded their shells of celestial form; that blown by Krishna was named Panchajanya; Arjun's, Devadatta. Bhim, of dreadful deeds, blew his capacious shell Powndra; and Yudisthira, the royal son of Kunti, founded Ananta-Vijaya. Nakul and Sahadeva blew their shells also, the one called Sugusha, the other Manipushpaka; so that their shrill sounding voices pierced the hearts of the Kurus, and echoed with a dreadful noise from heaven to earth." P. 29.

The shells in question are articles of commerce in India, to no inconsiderable extent. A chank fishery on the island of Ceylon is noticed by Mr. Cordiner. It is in the neighbourhood of Manaar, (see MANAAR,) and yields, Mr. Cordiner says, a considerable revenue to government. The shells, he says, are brought from the depth of two fathoms by divers, who in a calm day can, from a boat, see them crawling at the bottom. Such as are of a spiral form are chiefly exported to Bengal, where they are sawed into rings of various sizes, and worn on the arms, legs, fingers, and toes of the Hindoos, both male and female. A chank opening to the right, that is with its spiral line contrary to its usual direction, is rarely met with, and is highly valued by mystics and zealots. They always sell, Mr. Cordiner says, for their weight in gold. History of Ceylon, vol. ii. p. 6.

Univalves of the sort here alluded to, called *heterostrophous* by conchologists, are very rarely of any species, and are looked on with admiration in all countries; but with the enthusiastic Hindoo in a degree unequalled. A Yogi, or Saniassi of the Vaishnava sect, deems himself extremely happy in such an acquisition. The shell in question is frequently seen in the hands of itinerant holy beggars, and it is founded in some of the temples and religious ceremonies of the Hindoos.

**SHANK of an Anchor**, on board a Ship. See ANCHOR.

**SHANK of a Horse**, in the *Manege*, the name of that part of the fore-leg which is between the knee and the fetlock, or pattern joint. The larger and broader the shank is the better. It is known to be so, by the back sinew being at a distance from the bone, or well separated from it, and having no kind of swelling betwixt it and the bone, which may cause the leg to appear round.

**SHANK**, or *Shank-painter*, in a Ship, is a short chain fastened under the foremast-shrouds, by a bolt, to the ship's sides, having at the other end a rope fastened to it. On this shank-painter the whole weight of the aft part of the anchor rests, when it lies by the ship's side. The rope by which it is hauled up, is made fast about a timber-head. See PAINTER.

**SHANK**, *Sheep*, a sort of knot made on backstays, &c. to shorten them.

**SHANKER**, in *Medicine*. See CHANKRE.

**SHANKLIN CHINE**, in *Geography*, a ledge of rocks on the E. coast of the Isle of Wight, N. of Ludcomb Chine.

**SHANMUKA**, a name of a celebrated hero in *Hindoo Mythology*, more commonly called *Kartika*; which see. The name Shanmuka means with six months or faces, he being so represented; the reason of which is given under the article referred to. See also SESHTI-MATRIYA, another of his names.

**SHANNON**, in *Geography*, the chief river of Ireland, and the largest in any island in the world. The name is supposed to be derived from the Irish words *shan*, old, and *non*, a river. Other derivations, however, are given, all of which seem equally fanciful and uncertain; as the names of rivers are in general more ancient than even the names of the countries through which they flow. Ptolemy calls the Shannon *Senus*; Orosius, *Senna*; and Æthicus, *Secana*. It is called by Giraldus Cambrensis *Flumen Senuse*; who also

## SHANNON.

also dignifies it, as Virgil did the Po, with the title of *Fluviorum Rex*. Spenser too celebrates

“ The spacious Shenan spreading like a fea.”

And other poets have been eloquent in describing its majestic course, holy islands, and sublime scenery; but geographers are, in general, very brief, and sometimes contradictory in their accounts of this river. They do not even agree as to its source. According to Camden and Ware it rises in *Slieve-en-aron*, (*i. e.* the mountain of iron mines,) in the county of Leitrim; but Gough and Ferrar make it spring from the plains of Quilka, in the county of Cavan. Again, Dr. Beaufort says, Lough Clean is the fountain-head; while Boade, Pinkerton, and most other writers on the subject, make it Lough Allen. These differences, however, may be in some measure reconciled by observing, that Lough Allen receives the waters of the other sources above-mentioned, and that the Shannon does not take its name until it has passed this lake. As it is likewise the receptacle of most of the other current waters of the surrounding country, every stream that falls into it may claim some share in the disputed honour; but Lough Clean has the highest title, as contributing most largely by means of the river Duff. Lough Allen is nearly in the centre of the county of Leitrim; it is about twenty square miles in extent, and in some parts is said to be unfathomable. From this grand reservoir and copious spring, the Shannon issues in great force at a place called Balatnara. The direction, at first, is south and south-west, dividing the provinces of Leinster and Munster from Connaught. It passes Limerick, where it turns nearly to the west, and, sixty miles below this city, falls into the Atlantic ocean, between Kerry Head and Cape Lean, after a course of two hundred miles. It is navigable nearly to Limerick for ships of the greatest burden, and for smaller vessels throughout the whole extent of its course.

This noble river traverses several large lakes, and forms many extensive bays and estuaries, interspersed with beautiful islands. It receives above thirty other rivers in its course, and diffuses verdure and fertility over the banks of ten counties; namely, Leitrim, Roscommon, Galway, and Clare, on the right; and on the left, Longford, Westmeath, King's County, Tipperary, Limerick, and Kerry.

The principal towns situated on its banks are Leitrim, Carrick, Jamestown, Lanesborough, Athlone, Banagher, Portumna, Killaloe, Castleconnel, Tarbert, and Kilrush; besides the city of Limerick, which it encompasses by different branches, and in some measure insulates.

The largest lakes which it passes through are, Lough Boffin, Lough Ree or Regith, and Lough Derg or Dergart. The first, which is about ten square miles in extent, is situated at the confines of the counties of Leitrim, Longford, and Roscommon. Lough Ree extends nearly from Lanesborough to Athlone, a distance of about sixteen miles, and is from two to five miles in breadth. It contains above fifty islands, many of which are covered with wood and good pasturage. Lough Derg is eighteen miles long, and from two to seven broad. It is diversified with about sixty islands, one of which, called Innismore, contains above a hundred acres of good land; and on another, called the Holy Island, are the ruins of seven churches, and a round tower. This lake extends nearly from Portumna to Killaloe. There is also below Limerick, at the confluence of the Fergus river, an immense estuary, or firth, of many square miles in extent, interspersed with several rich and romantic islands.

The principal rivers that fall in from the right bank, or Connaught side, are the Key, Suck, Scariff, and Fergus. The confluence of the Key is at Carrick, and the Suck, which divides the counties of Roscommon and Galway, flows in at Clonfert above Banagher. Several smaller rivers fall in from the county of Galway; and from Clare flow the Scariff and Fergus; but the great weight of water comes from the other side by rivers running from east to west, which, it may be remarked, is different to the usual course in other parts of the world. The Inny is the first great river on the left bank: it is the boundary between the counties of Longford and Westmeath, and falls into Lough Ree, where it forms a large estuary. The second river on this side is the Great Brosna, which forms a fine confluence with the Shannon above Banagher; and the Lesser Brosna, united with the Birr river, falls in a few miles below that town. From hence to Limerick many smaller rivers flow in on the Ormond side, and below that city there are some larger ones: the principal are the Maig, Deel, Ovan, Cummage, Feale, Gale, and Cashin. Several of the above are navigable to a considerable distance from the Shannon.

From such an accumulation of rivers, lakes, and springs, the mouth of the Shannon is increased to an immense magnitude, being nearly ten miles in breadth, for the last fifteen miles, and from twenty to thirty fathoms deep. It is not only larger than any other insular river, but discharges much more water into the ocean than any continental stream whatever, running so short a distance as two hundred miles. Camden seems to credit a tradition, commonly believed in his time, of a gradual increase in the number and size of the lakes and rivers of Ireland. The supposition is curious, and may not be wholly unfounded.

As the Shannon from Limerick to the ocean is of great and increasing importance to the commercial world, we shall here give some particulars of its navigation from an hydrographical survey lately made. The distance is above sixty English miles, and the bearing nearly W. by S. The breadth of the river is various. If the length be divided into three parts, the first will be found to measure from one to three miles broad; the middle division increases to about six, and the third to ten miles in breadth. The foundings of the mouth have been already mentioned: they decrease towards Limerick; but in all parts the river is of considerable depth, and is remarkable for its transparency.

The tides in the mouth of the Shannon rise from nine to fourteen feet perpendicular height; and they increase as the river becomes narrower, inasmuch that at the pool of Limerick, they are from twelve to twenty feet high. The current of the tide varies considerably in different parts of the stream, running at the rate of from two to five miles an hour. It is not, however, perceptible far above the city, owing to several cataracts.

There are many fine bays on the Clare side, which afford safe anchorage and good shelter for shipping. The principal are Kilbahan, Carigahault, Clonderlaw, and Labisheda, besides the commodious harbour of Poolanishary, near Kilrush, and Tarbert bay on the Kerry side. It may be mentioned, that Kerry Head, also called Ballyheigh Point, is a long and narrow promontory; and that Cape Lean, or Loop Head, on the other side, is still narrower; having at its extremity a light-house, in N. lat.  $52^{\circ} 30'$ . W. long.  $10^{\circ} 20'$ .

The navigation between the Upper and Lower Shannon was formerly impeded by the noted cataract near Castleconnel, called the Salmon's Leap, but of late years canals have been drawn round this rock as well as others called the Falls. An important communication has been likewise opened between the Shannon and Dublin by means of the grand canal, which

which forms its junction above Banagher. (See our article CANAL.) It may be observed, that the Shannon nearly infulates Connaught with the county of Clare; and that if a canal, of about four miles in length, were cut from Lough Clean to the river Bonnet, which falls into Sligo bay, the insular boundary would be complete, and the Shannon rendered navigable from sea to sea.

The bridges over this river are chiefly at the forementioned towns, but there are none below Limerick. In this city there are three, one of which, called Thomond bridge, contains fourteen arches; and about ten miles higher is O'Brien's bridge, which has nineteen arches.

The fisheries on the Shannon are numerous and productive, particularly for salmon, which is of the finest flavour. Mr. Arthur Young, in his Tour through Ireland, p. 359, observes of this river, that "besides affording all sorts of wild fowl, the quantity and size of its fish are amazing. Pike's swarm and rise to the weight of 50lbs. each. Trout, bream, eel, gillaroos, &c. are large and abundant, and perch are so plentiful, that, in some years, the poor almost live upon them." It may be added, that not only river fish, but even such as are generally denominated pond and lake fish, abound here; so that what Spenser says of the Trent may be truly applied to the bounteous Shannon, which

— "Within itself encloses  
Both thirty forts of fish, and thirty fundry streames."

The Shannon forms a very important subject in the ancient history of Ireland. Ptolemy mentions three large cities on its banks, called Regia, Macolicum, and Regia Altera. But his editors, Mercator and Ortelius, do not exactly agree in their maps as to the situations, and no vestiges remain to settle the question. The general opinion is, that Regia was on the east side of Lough Ree, and the names correspond, as *Ree* signifies a *king*, in the Irish language. Macolicum is supposed, from the name, to have been at Mellick, a village in the county of Galway, and Regia Altera at or near Limerick.

This river was of great political and military use before the English power was established in Ireland. It long served as a barrier between the territories of provincial kings, and not unfrequently was made the scene of naval engagements, particularly below Limerick. The following curious instance is recorded in the Annals of Munster, and quoted by Archdall. "This year (1065), Hugh O'Ruark, king of Breifne, in company with Thady O'Kelly, king of Maine, were defeated by Hugh O'Connor, king of Connaught, who totally overthrew their whole army, and sunk and dispersed their fleet on the Shannon." (Monasticon Hibernicum, p. 280.) Even in modern times this river has been occasionally found of great military importance. See our articles ATHLONE, and LIMERICK.

The islands on the Shannon add an interesting feature to the history of the early progress of Christianity in Ireland; particularly from the fourth to the eighth century, when that country enjoyed a repose unknown on the continent, and was famed the "*Insula Sacra et Sanctorum*," or, to use the words of Dr. Johnson, "the pious and hospitable school of the west." During that period many of those islands were dedicated to the service of religion, and numerous vestiges still are seen in the remains of churches, abbeys, and other monastic institutions. The holy island in Lough Derg has been already noticed, and there are many others of a similar description, which are still held in pious veneration by the multitude, and are much resorted to on certain festivals. We shall mention only another, which is Inniscattery, in the mouth of the Shannon, about twenty miles

from the ocean, and which is thus described by Archdall. P. 49.

"On the rich and beautiful island of Scattery, are the ruins of a monastery dedicated to St. Senan, who founded here an episcopal see about the time of St. Patrick. There are likewise the ruins of seven churches, out of eleven which were here in queen Elizabeth's time. An ancient round tower of one hundred and twenty feet in height, and in complete repair, graces the scene." For a more particular account of these "*Insula sacra Senii*," see Gough's Camden; also Ware, Wilson, Archdall, &c.

The views of the Shannon are in many parts highly picturesque and sublime. We shall briefly notice three. The first is from a beautiful hill in Lower Ormond, called Knockshegowna, *i. e.* Oonagh's hill, so named as being the fabled residence of Oonagh, Spenser's Fairie Queen. From this eminence the river is seen to an extent of nearly twenty miles, apparently ascending in its course. The second is from the admired ruins of Carrick O'Gunnel, beyond Limerick; and the third from Knockpatrick, a lofty hill in the same county, and much nearer to the sea. It is celebrated by several writers as commanding the most grand and interesting prospect that can be imagined both of the river and the ocean. Among these authors may be mentioned Necham, an English poet and divine of the twelfth century; whose verses on the Shannon are thought worthy of quotation by Camden, and which we shall here transcribe, annexing a free translation.

"Fluminibus magnis lætatur Hibernia, Sineus  
Inter Connatiam, Momoniamque fluit.  
Transit per muros Limerici, Knoc Patric illum  
Oceanus clausum sub ditione videt."

"Amid majestic streams, Hibernia's pride,  
The noble Shannon bids her plains divide.  
Leinster and Munster to the eastward bear,  
With Connaught to the right, and lofty Clare;  
By Lim'rick's walls he bends his lordly way,  
While tributary streams their homage pay.  
Till proud Knockpatrick views, from Desmond's coast,  
This world of waters in the ocean lost."

SHANNON, a river of Canada, which runs into the N.E. part of lake Ontario.

SHANSCRIT, SANSKRIT, *Samskrit*, *Samskretam*, or *Hanskrit language*, is the original language of the Hiudoos or Gentoos, in which their *Shastah*, or *Shaster*, is written, &c.

The grand source of Indian literature, the parent of almost every dialect, from the Persian gulf to the China seas, says the learned Halked, in the Preface to his Grammar of the Bengal Language, is the Shanferit; a language of the most venerable and unfathomable antiquity, which, although at present shut up in the libraries of Bramins, and appropriated solely to the records of their religion, appears to have been current over most part of the oriental world; and traces of its original extent may still be discovered in almost every district of Asia. It is astonishing to find the similitude of Shanferit words with those of Persian and Arabic, and even of Latin and Greek; and those not in technical and metaphorical terms, which the fluctuation of refined arts and improved manners might have occasionally introduced; but in the main ground-work of language, in monosyllables, in the names of numbers, and in the appellations of such things as would be first discriminated in the immediate dawn of civilization. The coins of Assam, Nepal, Cashmere, and many other kingdoms, are all stamped

with Shanferit letters, and mollly contain allusions to the old Shanferit mythology: the same conformity is also observable in the impressions of seals from Bootan and Thibet. Besides, the arrangement of the Shanferit alphabet is very different from that of any other quarter of the world. This extraordinary mode of combination still exists in the greatest part of the East, from the Indus to Pegu, in dialects now apparently unconnected, and in characters completely dissimilar; and affords a forcible argument that they are all derived from the same source. Moreover, the names of persons and places, of titles and dignities, which are open to general notice, and which are found even to the furthest limits of Asia, present manifest traces of the Shanferit. Another circumstance deserves to be mentioned, and that is, that the raja of Kishenagur, a very learned and able antiquary of Bengal, affirmed, that he had in his own possession books which give an account of a communication formerly subsisting between India and Egypt, in which the Egyptians are described as disciples, and not as instructors; and as seeking that liberal education and those sciences at Hindoostan, which none of their own countrymen had sufficient knowledge to impart. But though these several proofs of the former prevalence of the Shanferit are now thinly scattered over an immense continent, and interspersed with an infinite variety of extraneous matter, arising from every possible revolution in the manners and principles of the nations who have by turns cultivated or destroyed it; that part of Asia, between the Indus and the Ganges, still preserves the whole language pure and inviolate; still offers a thousand books to the perusal of the curious, many of which have been religiously handed down from the earliest periods of human existence.

H. T. Colebrooke, esq. has given us in the Asiatic Researches (vol. vii. p. 199, &c.), a literal translation of two passages cited from a treatise on rhetoric, compiled for the use of Manicya Chandra, raja of Tirabhucti, or Tirlhut, in which are enumerated the languages used by Hindoo poets. The first is as follows: "Sanicrita, Pracrita, Paifachi, and Magad'hi, are in short the four paths of poetry. The gods, &c. speak Sanferita; benevolent genii, Pracrita; wicked dæmons, Paifachi; and men of low tribes and the rest, Magad'hi. But sages deem Sanferita the chief of these four languages. It is used three ways; in prose, in verse, and in a mixture of both." Again, "Language, the virtuous have declared to be fourfold, Sanferita, or the polished dialect; Pracrita, or the vulgar dialect; Apabhransa, or jargon; and Misra, or mixed. Sanferita is the speech of the celestials, framed in grammatical institutes; Pracrita is similar to it, but manifold as a provincial dialect, and otherwise; and those languages which are ungrammatical, are spoken in their respective districts." The Paifachi, says Mr. Colebrooke, seems to be gibberish, which dramatic poets make the dæmons speak, when they bring these fantastic beings on the stage. The mixture of languages, noticed in the second quotation, is that which is employed in dramas, as is expressly said by the same author in a subsequent verse. It is not then a compound language, but a mixed dialogue, in which different persons of the drama employ different idioms. Both the passages above quoted are therefore easily reconciled. They, in fact, notice only three tongues. 1. Shanferit, a polished dialect, the inflexions of which, with all its numerous anomalies, are taught in grammatical institutes. This the dramatic poets put into the mouths of gods and of holy personages. 2. Pracrit, consisting of provincial dialects, which are less refined, and have a more imperfect grammar. In dramas it is spoken by women, benevolent genii, &c.

3. Magad'hi, or Apabhransa, a jargon destitute of regular grammar. It is used by the vulgar, and varies in different districts: the poets accordingly introduce into the dialogue of plays a provincial jargon, spoken by the lowest persons of the drama.

*Sanferita* is the passive participle of a compound verb, formed by prefixing the preposition *sam* to the crude verb *cri*, and by interpolating the letter *s*, when this compound is used in the sense of embellishment. Its literal meaning then is "adorned;" and when applied to a language, it signifies "polished." *Pracrita* is a similar derivative from the same crude verb, with *pra* prefixed: the most common acceptation of this word is "outcast, or man of the lowest class;" as applied to a language, it signifies "vulgar." *Apabhransa* is derived from *bhras*, to fall down: it signifies a word, or dialect, which falls off from correct etymology. Grammarians use the *Sanferita* as signifying "duly formed or regularly inflected;" and *Apabhransa* for false grammar.

The languages of India are all comprehended in these three classes. The first contains Shanferit, a most polished tongue, which was gradually refined until it became fixed in the classic writings of many elegant poets, most of whom are supposed to have flourished in the century preceding the Christian era. It is cultivated by learned Hindoos throughout India, as the language of science and of literature, and as the repository of their law, civil and religious. It evidently draws its origin (and some steps of its progress may even now be traced) from a primeval tongue, which was gradually refined in various climates, and became Shanferit in India; Pahlavi in Persia; and Greek on the shores of the Mediterranean. Like other very ancient languages, Shanferit abounds in inflexions, which are, however, more anomalous in this, than in the other languages here alluded to; and which are even more so in the obsolete dialect of the Vedas, than in the polished speech of the classic poets. It has nearly shared the fate of all ancient tongues, and is now become almost a dead language; but there seems no good reason for doubting, that it was once universally spoken in India. Its name, and the reputed difficulty of its grammar, have led many persons to imagine, that it has been refined by the concerted efforts of a few priests, who set themselves about inventing a new language; not like all other tongues, by the gradually improved practice of good writers and polite speakers. The exquisitely refined system by which the grammar of Shanferit is taught, has been mistaken for the refinement of the language itself. The rules have been supposed to be anterior to the practice, but this supposition is gratuitous. In Shanferit, as in every other known tongue, grammarians have not invented etymology, but have only contrived rules to teach what was already established by approved practice.

There is one peculiarity of Shanferit compositions which may also have suggested the opinion, that it could never be a spoken language. Mr. Colebrooke alludes to what might be termed the euphonical orthography of Shanferit. It consists in extending to syntax the rules for the permutation of letters in etymology. Similar rules for avoiding incompatible sounds in compound terms exist in all languages; this is sometimes effected by a deviation from orthography in the pronunciation of words, sometimes by altering one or more letters to make the spelling correspond with the pronunciation. These rules have been more profoundly investigated by Hindoo grammarians than by those of any other nation, and they have completed a system of orthography, which may be justly termed euphonical. They require all compound terms to be reduced to this standard, and Shanferit authors, it may be observed, delight in compounds of inordinate

ordinate length; the whole sentence too, or even whole periods, may, at the pleasure of the author, be combined like the elements of a single word, and good writers generally do so. In common speech this could never have been practised. None but well-known compounds would be used by any speaker who wished to be understood, and each word would be distinctly articulated, independently of the terms which precede and follow it. Such indeed is the present practice of those who still speak the Shanferit language; and they deliver themselves with such fluency as is sufficient to prove, that Shanferit may have been spoken in former times with as much facility as the contemporary dialects of the Greek language, or the more modern dialects of the Arabic tongue.

The father of Shanferit grammar, who first composed those grammatical institutes in which this language is formed, or by which words are correctly formed or inflected, was Panini, who lived in so remote an age, that he ranks among those ancient sages, whose fabulous history occupies a conspicuous place in the "Puranas," or Indian theogonies. According to the Pauranica legends, Panin was the grandson of Devala, an inspired legislator; but whatever may be his history, to him the Sutas, or fuccinct aphorisms of grammar, are attributed by universal consent.

His system is grounded on a profound investigation of the analogies in both the regular and the anomalous inflexions of the Shanferit language. He has combined those analogies in a very artificial manner; and has thus compressed a most copious etymology into a very narrow compass. His precepts are indeed numerous, but they have been framed with the utmost conciseness; and this great brevity is the result of very ingenious methods which have been contrived for this end, and for the purpose of affixing the student's memory. In Panini's system the mutual relation of all the parts marks that it must have been completed by its author; it certainly bears internal evidence of its having been accomplished by a single effort, and even the corrections, which are needed, cannot be interwoven with the text. It must not be hence inferred, that Panini was unaided by the labours of earlier grammarians; in many of his precepts he cites the authority of his predecessors, sometimes for a deviation from a general rule, often for a grammatical canon which has universal cogency. He has even employed some technical terms without defining them, because, as his commentators remark, those terms were already introduced by earlier grammarians. None of the more ancient works, however, seem to be now extant; being superseded by his, they have probably been disused for ages, and are now perhaps totally lost.

The inaccuracies of the Paniniya grammar were corrected by Catyayana, an inspired saint and lawgiver, whose history is involved in the impenetrable darkness of mythology. The amended rules of grammar have been formed into memorial verses by Bhartri-hari, whose metrical aphorisms, entitled "Carica," have almost equal authority with the precepts of Panini, and emendations of Catyayana. Bhartri-hari is said to have lived in the century preceding the Christian era. The text of Panini being concise and ambiguous, many commentaries were composed to elucidate it, of the chief of which Mr. Colebrooke has given an account. The best and most concise commentary now extant, is entitled the "Castica vritti," or commentary composed at Varanasi. Within a few centuries past, a grammar, well adapted for aiding the student in acquiring a critical knowledge of the Shanferit tongue, has been compiled by Ramachandra, entitled "Pracriyacannudi."

When Shanferit was the language of Indian courts, and was cultivated not only by persons who devoted themselves

to religion and literature, but also by princes, lawyers, soldiers, physicians, and scribes; in short, by the first three tribes, and by many classes included in the fourth; an easy and popular grammar must have been needed by persons who could not waste the best years of their lives in the study of words. Such grammars must always have been in use; those, however, which are now studied are not, we believe, of very ancient date. The most esteemed is the "Sarawata," together with its commentary named "Chandrica." It seems to have been formed on one of the Caumudis, by translating Panini's rules into language that is intelligible, independently of the gloss, and without the necessity of adverting to a different context.

Another popular grammar, which is in high repute in Bengal, is entitled "Mugd'habod'ha," and is accompanied by a commentary. It is the work of Vopadeva, and proceeds upon a plan grounded on that of the Caumudis; but the author has not been content to translate the rules of Panini, and to adopt his technical terms. He has, on the contrary, invented new terms, and contrived new abbreviations. The same author likewise composed a metrical catalogue of verbs alphabetically arranged. It is named "Cavicalpadruma," and is intended as a substitute for the "D'hatupata."

The best and most esteemed vocabulary of the Shanferit is the "Amera cosha," which, like most other Shanferit dictionaries, is arranged in verse to aid the memory. Numerous commentaries have been written on this vocabulary; the chief object of which is to explain the derivations of the nouns, and to supply the principal deficiencies of the text. Shanferit etymologists scarcely acknowledge a single primitive amongst the nouns. When unable to trace an etymology which may be consistent with the acceptation of the word, they are content to derive it according to grammatical rules from some root to which the word has no affinity in sense. At other times they adopt fanciful etymologies from Puranas or from Tantras. But in general the derivations are accurate and instructive.

Amera's dictionary does not contain more than ten thousand different words. Yet the Shanferit language is very copious. The insertion of derivatives, that do not at all deviate from their regular and obvious import, has been very properly deemed superfluous. Compound epithets, and other compound terms, in which the Shanferit language is peculiarly rich, are likewise omitted; excepting such as are especially appropriated, by a limited acceptation, either as titles of deities, or as names of plants, animals, &c. In fact, compound terms are formed at pleasure, according to the rules of grammar; and must generally be interpreted in strict conformity with those rules. Technical terms too are mostly excluded from general dictionaries, and consigned to separate nomenclatures. The "Ameracosh" then is less defective than might be inferred from the small number of words explained in it. Still, however, it needs a supplement. The remaining deficiencies of the Ameracosh are supplied by consulting other dictionaries and vocabularies, which are very numerous.

The Shanferit language is very copious and nervous; but the style of the best authors wonderfully concise. It far exceeds the Greek and Arabic in the variety of its etymology, and, like them, has a prodigious number of derivatives from each primary root. The grammatical rules are also numerous and difficult, though there are not many anomalies. "The Shanferit language," says sir William Jones, (Asiat. Ref. vol. i. p. 422.) "whatever be its antiquity, is of a wonderful structure, more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either; yet bearing to both of them a stronger affinity, both

both in the roots of verbs, and in the forms of grammar, than could possibly have been produced by accident; so strong, indeed, that no philologer could examine them all three without believing them to have sprung from some common source, which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a very different idiom, had the same origin with the Shanferit, and the old Persian might be added to the same family."

The fundamental part of the Shanferit language is divided into three classes; viz. *dhāt*, or roots of verbs, *śabd*, or original nouns, and *avya*, or particles. The latter are always indeclinable, as in other nations; but the words comprehended in the two former classes must be prepared by certain additions and inflexions to fit them for a place in composition. Here the art of the grammarian interposes, as not a syllable, nor a letter, can be added or altered but by regimen, nor the most trifling variation of the sense in the minutest subdivision of declension or conjugation can be effected without the application of several rules; and all the different forms for every change of gender, number, case, person, tense, mood or degree, are methodically arranged for the assistance of the memory; resembling, though on an infinitely more extensive scale, the compilations of *propria quæ maribus* and *as in præfenti*.

In the Shanferit language, the three distinctions of genders, viz. masculine, feminine, and neuter, are preserved in their common number and order. A Shanferit noun, in its first formation from the general root, exists equally independent of case as of gender. It is neither nominative, nor genitive, nor accusative, nor is impressed with any of those modifications, which mark the relation and connection between the several members of a sentence. In this state it is called an *imperfect*, or *crude* noun. To make a nominative any noun, the termination must be changed, and a new form supplied. Thus we see that, in the Shanferit at least, the nominative has an equal right with any other inflexion to be called a case. The Shanferit has seven declensions of nouns, which are all used in the singular, dual, and plural number, and differently formed, as they terminate with a consonant, and with a long or short vowel; and also as they are of different genders. The seven changes of inflexion are exclusive of the vocative, and therefore the Shanferit comprehends two more than even those of the Latin: they are as follow, viz. 1. The nominative, or *agent* in a sentence; 2. The passive case, or *subject* of the action; 3. The *causal* case, pointing out the cause *by* which a thing is done; or the instrument *with* which it is done; or the subject *in* or *by* which it is suffered; 4. The dative, with the sign *to* or *for*; 5. The ablative, implying the subject *from* whence any thing proceeds; 6. The *possessive* case, called by us the genitive; 7. The *locative* case, definitive of situation, and generally known by the sign *in*. The vocative is excluded from the number of cases, as no inflexion is employed in its formation.

The Shanferit, the Arabic, the Greek, and the Latin verbs are furnished with a set of inflexions and terminations so comprehensive, and so complete, that by their form alone they can express all the different distinctions both of person and time. Three separate qualities are in them perfectly blended and united. Thus by their root, they denote a particular act; and by their inflexion, both point out the time when it takes place, and number of the agents. Every Shanferit verb has a form equivalent to the middle voice of the Greek, used through all the tenses with a reflective sense; and the former is even the most extensive of the two in its use and offices; for in Greek the reflective idea can only be adopted intransitively, when the action of the verb descends to no extraneous subject; but in Shanferit the

verb is both reciprocal and transitive at the same time. The verb substantive of the Shanferit very nearly resembles those of the Greek and Latin; but perhaps it would not be suspected that all the verbs in *mi* are formed exactly upon the same principle with the Shanferit conjugations, even in the minutest particulars. All the terms which serve to qualify, to distinguish, or to augment either *substance* or *action*, are classed by the Shanferit grammarians under a head, literally signifying *increase* or *addition*. According to this arrangement, a simple sentence consists of three numbers: the agent, the action, and the subject; which, in a grammatical sense, are reduced to two, viz. the noun (whether agent or subject) and the verb. All such words as tend to specify or to amplify the noun, are denominated by a term which signifies *adjectives* or *epithets*; and such as are applied to denote relation or connection, are called *connectives of nouns*, and by European grammarians, *prepositions*: those particles which in any manner affect the verb are denominated *attributes of verbs*.

The Shanferit alphabet contains fifty letters; and it is one boast of the Bramins, that it exceeds all other alphabets in this respect. But when we consider that of their thirty-four consonants, nearly half are combined sounds, and that six of their vowels are merely the correspondent long ones to as many which are short, the advantage seems to be little more than imaginary. The Shanferit character, used in Upper Hindoostan, is said to be the same original letter that was first delivered to the people by Brihma, and is called *Diewnagur*, or the language of angels; whereas the character used by the Bramins of Bengal is by no means so ancient, and is evidently a corruption of the former. In the four beids, or vedas, which constitute the original and sacred text of the great Hindoo creator and legislator Brihma, the length of the vowels is expressed by a musical note or sign placed over every word; and in reading the beids, these distinctions of tone and time must be nicely observed; so that they produce all the effect of a laboured recitative. It is remarkable, that the Jews in their synagogues chant the Pentateuch in the same kind of melody, and it is supposed that this usage has descended to them from the remotest ages. Some writers have erroneously asserted, that the four beids are in verse; whereas they are written in a kind of measured prose; and they are now scarcely intelligible to the most learned pundits or lawyers; they are also scarce, and difficult to be found. However, comments have been written upon them from the earliest periods; of which one of the most ancient and approved was composed by Biseht Mahamomè, or the Most Wise, a great writer and prophet, who is said to have lived in the suttee jogue, or first age of the world. See Halhed's Preface to his translation of the Code of Gentoo Laws, printed in 1776.

Dr. Leyden, in his account of the languages and literature of the Indo-Chinese nations, (*Asiatic Researches*, vol. x.) has shewn, that the "Pali," as it is generally written, or "Bali" language, as it is commonly pronounced, occupies the same place among the Indo-Chinese nations, which Shanferit holds among the Hindoos, or Arabic among the followers of Islam. Throughout the greater part of the maritime countries, which lie between India and China, it is the language of religion, law, literature, and science, and has had an extensive influence in modifying the vernacular language of those regions. La Loubere, on the authority of d'Herbelot, has stated that the ancient Persian language was termed *Pahalevi* (*Pahlavi*), and that the Persians do not distinguish in writing between *Pahali* and *Bahali*. P. Paulinus, however, applies this term *Bali* inaccurately to the square *Bali* character, instead

of the language. This language, notwithstanding its extensive use among so many nations, and the degree of cultivation which it has received from the different tribes by whom it is employed, has hitherto attracted little attention among Europeans. The Bali alphabet, according to Dr. Leyden, seems, in its origin, to be a derivative from the Deva-nagari, though it has not only acquired considerable difference of form, but has been also modified to a certain degree, in the power of the letters, by the monosyllabic pronunciation of the Indo-Chinese nations. The form of the Bali character varies essentially among the different nations by whom it is used.

The Bali is an ancient dialect of Shanferit, which sometimes approaches very near the original. When allowance is made for the regular interchange of certain letters, the elision of harsh consonants, and the contraction of similar syllables, all the vocables which occur in its ancient books, seem to be purely Shanferit. In Cheritas and later compositions, however, some words of the popular languages of the country sometimes insinuate themselves, in the same manner as Tamil, Teluga, and Canara vocables occasionally occur, in the later Shanferit compositions of the Dekhin. The Bali, while it retains almost the whole extent of Shanferit flexions, both in nouns and verbs, nevertheless employs this variety rather sparingly in composition, and affects the frequent introduction of the preterite participle, and the use of impersonal verbs. It also uses the cases of nouns in a more indeterminate manner than the Shanferit, and often confounds the active, neuter, and passive tenses of verbs. Like other derivative dialects, it occasionally uses Shanferit nouns and particles in an oblique sense; but notwithstanding all these circumstances, it approaches much nearer the pure Shanferit, than any other dialect, and exhibits a close affinity to the Prakrit, and the Zend.

These three dialects, the Prakrit, the Bali, and the Zend, are probably the most ancient derivatives from the Shanferit. The great mass of vocables in all the three, and even the forms of flexions, both in verbs and nouns, are derived from the Shanferit, according to regular laws of elision, contraction, and permutation of letters. Sometimes, in pursuing these analogies, they nearly coincide, sometimes they differ considerably, sometimes one, and sometimes another of them approaches nearest to the original Shanferit. Their connection with this parent language was perceived, and pointed out by Sir W. Jones, and has also been alluded to by P. Paulinus, who derives his information, concerning the Bali, from Carpanius and Mantegatius. The fate of these three languages is also, in some degree, similar. The Prakrit is the language which contains the greater part of the sacred books of the Jainas; the Bali is equally revered among the followers of Budd'ha; while the Zend, or sacred language of ancient Iran, has long enjoyed a similar rank among the Persis or worshippers of fire, and been the depositary of the sacred books of Zoroaster. It is perhaps, however, more accurate to consider all the three, rather as different dialects of the same derivative language, than as different languages; and conformably to this idea, the Bali itself may be reckoned a dialect of Prakrit. The term Prakrit, both in books, and in common use among the Bramins, is employed with some degree of latitude. Sometimes the term is confined to a particular dialect employed by the Jainas, as the language of religion and science, and appropriated to females, and respectable characters of an inferior class, in dramas. Sometimes it includes all the dialects derived immediately from the Shanferit, whether denominated Prakrit, Magad'hi, Suraseni,

Paifachi, or Apabhransa; and sometimes it is even extended to the Desab'hasas, or popular tongues of India, as Mahrasht or Mahratta, Canara, Telinga, Udia and Bengali. According to the extended use of the term Prakrit, it may certainly include both Bali and Zend; and if more extensive research should justify the idea derived from an imperfect investigation, Dr. Leyden apprehends that the Bali may be identified with the Magad'hi, and the Zend with the Suraseni, of Shanferit authors.

These three dialects, the Prakrit, Bali, and Zend, have been regularly cultivated and fixed by composition. The same laws of derivation are applicable to the formation of all the three; but yet there is often considerable diversity in the forms which particular words assume, as appears from the comparative specimen given by Dr. Leyden.

The learned Mr. Colebrooke has published in the 10th volume of the Asiatic Researches, an elaborate essay on Shanferit and Prakrit poetry. He observes, that the prosody of Shanferit will be found, from the examples which he has adduced, to be richer than that of any other known language, in variations of metre, regulated either by quantity or by number of syllables, both with and without rhyme, and subject to laws imposing in some instances rigid restrictions, in others allowing ample latitude. The rules relative to Prakrit prosody, are applicable, for the most part, to Shanferit prosody also; since the laws of versification in both languages are nearly the same.

Shanferit prosody admits of two sorts of metre; one governed by the number of syllables; and which is mostly uniform or monoschematic in profane poetry, but altogether arbitrary in various metrical passages of the Vedas. The other is in fact measured by feet, like the hexameters of the Greek and Latin: but only one sort of this metre, which is denominated *Arya*, is acknowledged to be so regulated; while another sort is governed by the number of syllabic instants or *matras*.

The most common Shanferit metre is the stanza of four verses, containing eight syllables each; and denominated from the name of the class "Anushtubh," for an account of which, and of other kinds of metres, we refer *ubi supra*.

The Shanferit writers notice different species of prose. They discriminate three and even four sorts, under distinct names. 1. Simple prose, admitting no compound terms. It is denominated "Muctaea." This is little used in polished compositions; unless in the familiar dialogue of dramas. It must undoubtedly have been the colloquial style, at the period when Shanferit was a spoken language. 2. Prose, in which compound terms are sparingly admitted. It is called "Culaca." This and the preceding sort are by some considered as varieties of a single species named Churnica. It is of course a common style of composition: and, when polished, is the most elegant as it is the chaste. But it does not command the admiration of Hindoo readers. 3. Prose abounding in compound words. It bears the appellation of "Utealica praya." Examples of it exhibit compounds of the most inordinate length: and a single word exceeding a hundred syllables is not unprecedented. This extravagant style of composition, being suitable to the taste of the Indian learned, is common in the most elaborate works of their favourite authors. 4. Prose modulated so as frequently to exhibit portions of verse. It is named "Vrittigand'hi." It will occur without study, and even against design, in elevated compositions; and may be expected in the works of the best writers.

Some of the most elegant and highly wrought works in prose are reckoned among poems, as already intimated, in like

like manner as the "Telemache" of Fenelon and "Tod Abels" of Gefner. The most celebrated are the "Vafavadatta" of Subandhu, the "Dafa Cumara" of Dandi, and the "Cadambari" of Vana.

For a further account of the Shanscrit, see *Language of BENGAL*, or *BENGALESE*.

Exclusive of the Shanscrit, there are three different dialects in the kingdom of Bengal, *viz.* the Persian, the Hindoostanic, and the proper Bengalese. See *PERSIA* and *PERSIAN Language*, *HINDOOSTANEE*, and *BENGALESE*.

SHAN-SI, in *Geography*. See *CHAN-SI*.

SHAONA, a town of Egypt, on the W. coast of the Red sea; 90 miles S.S.E. of Cofseir.

SHAOSUMRE, a town of Arabia, in the province of Hedsjas; 25 miles from Calaat el Moilah.

SHAOUN, a town of Arabia, in the province of Hedsjas; 45 miles S. of Jambo.

SHAPARY, a town of Hindoostan, in the circar of Gangpou; 30 miles S.W. of Pada.

SHAPE, *Inflammation of, among neat cattle*, an affection in cows, arising in hot weather after taking the bull; and which is shewn by a swelling of the parts with boils or eruptions. It is observable by the animal rubbing her hind parts in the hedges, &c. In the cure Mr. Downing advises, after free bleeding, the following: Nitre in powder, two ounces; cream of tartar, three ounces; Castile soap, one ounce; and aniseed powder, one ounce; which are to be mixed for a dose, and to be given in a quart of warm whey, repeating them as there may be occasion.

To SHAPE the Course, in *Sea Language*, is to direct or appoint the track of a ship, in order to prosecute a voyage.

SHAPINSAY, in *Geography*, one of the Orkney islands, Scotland, is situated to the N. of the Mainland of Orkney, at the distance of three miles from Kirkwall, the capital of all the islands. It measures about seven miles in length and five in breadth, and formerly constituted part of the temporalities of the bishopric of Orkney. Almost the whole of it is capable of cultivation; but a great part yet remains in a neglected state, to the detriment, as well as the disgrace of the proprietors. Nevertheless, sufficient grain is raised for the supply of the inhabitants. Kelp is produced in great abundance, and is much used as a manure. Lead ore is likewise abundant in the south-west corner of this island, and was for some time wrought, but the work is now entirely abandoned.

In common with most of the Orkney islands, Shapinsay exhibits some monuments of antiquity: among these may be reckoned, besides several Popish chapels, a numerous collection of Picts-houses ranged along the shores, like so many forts, together with tumuli, or barrows, in various situations. A monumental stone of large dimensions raises its venerable head in a plain near its eastern extremity; and on the northern shore is the stone Odin.

To the south of Shapinsay, at the distance of a furlong, is situated the beautiful islet of Elgar or Ellerholm, which bears evident traces of former habitation, and of having been, at no very distant period, attached to the principal island. At present it furnishes pasture for a number of sheep and young cattle during summer, and serves to give, by its favourable position, the utmost security to the harbour of Elwick, which is one of the finest in the Orkneys. Barry's *History of the Orkney Islands*, 2d edit. by J. Headrick, Lond. 4to. 1808.

SHAPLEIGH, a post-town of America, in Massachusetts, in the province of Maine, incorporated in 1785; 108 miles N. of Boston.

SHAPOOTA HILLS, a mountainous ridge of Hindoostan, between the Nerbuddah and Taptee; 60 miles E. of Surat.

SHAPORA, a town of Hindoostan, in the circar of Rantampour; 45 miles W. of Rantampour.

SHAPOUR, a city of Persia, in the province of Farfistan, is said to have been originally founded by Taimuras Devedund, who called it Deen Dar; it was destroyed by Alexander the Great, and subsequently built by Sapor, the son of Artaxerxes Babegan, who named it after himself. The ruins of this ancient city are distant about 16 miles from Kazeroon: and if we may form an idea from the breadth and circumference of the ramparts, and the remains of some other public buildings, it must have been a city of great extent and magnificence. It is situated immediately under the eastern range of mountains, on the banks of a small but rapid river, and in a wild, romantic spot, amidst rocks and precipices, many of which are decorated with pieces of sculpture similar to those near Persepolis, for a description of which we refer to Kinneir's *Memoir of the Persian Empire*, p. 66. The hills in the immediate vicinity of these ruins appear to have been formerly fortified; and an extraordinary cavern, further up the river, has given rise to many fabulous stories.

SHAPS, an island in the Chesapeake; 27 miles S.S.E. of Annapolis. N. lat.  $38^{\circ} 46'$ . W. long.  $76^{\circ} 25'$ .

SHAR, or SHEAR-Hog, in *Agriculture*, a term signifying a yearling sheep, which has been once shorn. The same as lamb-hog. See SHEEP.

SHARAF BENI GATEI, in *Geography*, a town of Arabia, in the province of Hedsjas; 25 miles N. of Madian.

SHARBASHI, a town of Turkish Armenia; 18 miles S.E. of Moush.

SHARBIN, a town of Egypt; 16 miles S.S.W. of Damietta.

SHARD, in *Agriculture*, a term applied to a fragment of an earthen vessel, or the gap in a hedge.

SHARE of a Plough, that part which enters, cuts, and breaks up the ground, the extremity forward being formed with a sharp-pointed iron, called the point of the share; and the end towards the wood behind, the tail of the share. This part constitutes a portion of what is usually denominated the *throat*, which is of very great importance in the construction of this implement. (See *PLOUGH*.) The dimensions are these: the length of the whole share from point to tail, according to Tull, should be three feet nine inches, but in modern ploughs much shorter; at the top of the iron it hath sometimes an upright piece called the fin; and near the iron, at the other end, there is an oblong-squared hollow called the socket; the use of which is to receive the bottom of the sheat. Near the tail there is a thin plate of iron, well rivetted to the wood; by means of this plate, the tail of the share is held firmly to the hinder sheat of the plough by a small iron-pin, with a screw at the end, and a nut screwed on it, on the inner or right side of the sheat. But shares are made in different forms.

The point of the share is that part in which it does not run up to the fin; this point is generally made three inches and a half in length, and should be flat underneath, and round at the top, and the lower part of it must be of hard steel. The edge of the fin should also be well steeled, and should make an acute angle with the share. The socket is a sort of mortise: it should be a foot long and about two inches deep: the fore-end of it must not be perpendicular, but oblique, conformable to the end of the sheat which enters into it. The upper edge of the fore-part must be always

always made to bear up against the sheat; but if this end of the socket should not be quite so oblique as the sheat, it may be helped by paring off a small part of the wood at the point.

However, in modern ploughs, the shares, as has been seen, are very different, according to their constructions and the uses for which they are intended.

Lately, improved cast-iron plough-shares have been made by R. Ransome, of Ipswich, Suffolk, for which he has obtained a patent. These shares are made hard on one side and soft on the other, which affords the great advantage of wearing them, as it is found by farmers that those made in the common way wear thick, with a basil on the under side, which obstructs their entering into hard or strong soils, and at the same time increase the labour of the team, as well as pass over weeds without cutting or eradicating them. The same person also makes *plough-grounds*, which are so contrived, as that by turning a screw the plough is made to work more or less to the land with the greatest ease and facility. And both these contrivances are said to be capable of being applied to all sorts of ploughs which have been already constructed, and are in use upon farms.

The *broad share*, which is used in Suffex, is said to be a capital contrivance, whether invented in that district or in Kent. Its great use is in cutting over pea and bean stubbles, or such weedy fallows as do not require ploughing. It consists of an oblong share two feet long, and four or five inches wide, fixed to the stock or front of the ground rest, by an iron shank in the middle, and occasionally bolted to the side of the same rest of a wheel-plough. It is pitched with an inclination into the ground, capable of being raised or sunk at pleasure, by the elevation or depression of the beam on the gallow, answering the purpose of the great skim of the isle of Thanet, described in Young's Eastern Tour. When the rubbles have been cut over with this tool, they are harrowed, raked, and burnt, the land being left in excellent order for wheat.

On cast-iron plough-shares a very simple and beneficial improvement has lately been made by a person of the name of Morland, in Berkshire. It is well known that when the point, or sock, of wrought-iron plough-shares wears out, they are capable of being renewed; but that, in cast-iron, the case is otherwise. By this invention and improvement, however, which is much approved of in the above county, the blunt point is capable of being dipped or depressed in such a manner as to produce every effect which is wanted by the ploughman, when the share must have become quite useless without it. The cheapness and durability of cast-iron plough-shares render them highly desirable in all farming concerns where there is much ploughing to be done.

The whole is accomplished by the share having a sort of joint, and the top part taking in and out, and by a tuck that goes through the beam of the plough, which raises or falls the point of the share.

*SHARE-Grass*, provincially a sort of sedge.

*SHAREMAN'S CREEK*, in *Geography*, a river of Pennsylvania, which runs into the Susquehanna, N. lat.  $40^{\circ} 20'$ . W. long.  $77^{\circ} 5'$ .

*SHARK*, in the Linnæan system of *Ichthyology*, is a species of the squalus. Pennant makes it a distinct genus, the characters of which are these; the body is slender, and grows less towards the tail; it has two fins on the back; a rough skin; five apertures on the sides of the neck; the mouth generally placed far beneath the end of the nose; and the upper part of the tail longer than the lower. We know two different fish under the same name of shark, with the addition of their colour, blue and white.

VOL. XXXII.

The blue shark is that species of squalus called *glaucus*, and *galeus glaucus*, by authors, and distinguished by Artedi by the name of the squalus with a triangular dent, or furrow, in the extremity of the back, and with no foramina about the eyes. It is of a fine deep blue colour on the back, and of a bright silver white on the belly; the skin is smoother than that of the white shark, and the nose long pointed, and somewhat flattened, and extending far beyond the mouth; the nostrils are long, and placed transversely; the tail is bifid, and one portion of it is much larger than the other; it is very voracious of human flesh, and will follow close under the shore if there be depth enough, and a man is walking there. It is sometimes found on the English shores, and has been caught on the Cornwall coast, during the pilchard season, with large iron hooks, made on purpose. Ælian informs us, that this fish will permit the small brood, when in danger, to swim down its throat, and take shelter in its belly; and the fact has been confirmed by Rondeletius. Mr. Pennant apprehends that this care of their young is not peculiar to this species, but common to the whole genus of shark.

The other is the *lamia*, or *canis carcharias* of authors, the *squalus carcharias* of Linnæus, commonly called by us simply *the shark*. This is distinguished by Artedi by the name of the squalus with a flat back, and with numerous teeth, serrated at the edges.

The white shark, or *lamia*, is a very dreadful and voracious fish, the largest of all the sharks. They have been seen of four thousand weight, with throats capable of swallowing a lusty man whole; nay, men have been found whole in them when opened. Some have, for this reason, imagined this, and not the whale, to have been the fish in whose belly the prophet Jonah lay. Swimmers very often perish by them; sometimes losing an arm or leg, and sometimes being bit quite asunder, and serving only for two morsels for this ravenous animal. Its teeth are very sharp and terrible; they are disposed in six rows, and are all triangular, and notched like a saw on their edges; these are, in the whole, a hundred and forty-four in number, and are placed in various directions; their number is not exactly determinate; these teeth, when the fish is in a state of repose, lie quite flat in the mouth, but when he seizes his prey, he has power of erecting them, by the help of a set of muscles that join them to the jaw; the mouth is placed far beneath; on which account these fishes, as well as the rest of the kind, are said to be obliged to turn on their backs to seize their prey; which is an observation as ancient as the days of Pliny: its back is short and broad, in comparison of the other fish of this kind, and its tail, which is of a semi-lunar form, composed of two fins of a cubit in length each. This fish has surprising strength in its tail, and can strike with great force; so that the sailors instantly cut it off with an ax, as soon as they draw one on board. The pectoral fins are very large, which enable it to swim with great swiftness; the colour of the whole body and fins is a light ash; its skin is rough, and its eyes large and round. It is found both in the ocean and in the Mediterranean, and is of all fish the most voracious of human flesh.

It has its name from the Greek *λαμπος*, a voracious feeder, or *glutton*. The fossil bodies, called *glossopetra*, or serpents' tongues, and supposed to be real bones, are the teeth of this fish.

*SHARK, Basking*, *Squalus maximus* of Linnæus, the name given by Mr. Pennant to a fish which inhabits the northern seas, as high as the arctic circle, and which was taken for a species of whale, till he pointed out the branchial orifices in the sides, and the perpendicular site of the tail.

This species has been long known to the inhabitants of the south and west of Ireland and Scotland, and those of Caernarvonshire and Anglesea; they quit the bays of these Welsh counties about Michaelmas, and the frith of Clyde, and the Hebrides, about the latter end of July. They have nothing of the fierce and voracious nature of the shark kind, but are so tame as to suffer themselves to be stroked; lying motionless on the surface of the water, commonly on their bellies, but sometimes on their backs, as if to sun themselves; whence they are called basking sharks. Their food seems to consist entirely of sea-plants. Linnæus says they feed on medusæ. At certain times they are seen sporting on the waves, and leaping with great agility several feet out of the water; they swim deliberately, with the dorsal fins above water; their length is from three to twelve yards, and they are sometimes longer; their form is slender; the upper jaw much longer than the lower, and blunt at the end; the mouth placed beneath, and each jaw furnished with numbers of small teeth; those before being much bent, and those more remote in the jaws being conic, and sharp-pointed; on the sides of the neck there are five large transverse apertures to the gills; on the back two fins; the first very large, nearer the head than the middle; the other small, and situated near the tail; on the lower part there are five others; viz. two pectoral fins, two ventral fins, and a small anal fin; near these, the male has two genitals, as in other sharks; and between these fins was situated the pudendum of the female; the tail very large, having the upper part much longer than the lower; the colour of the upper part of the body a deep leaden, and the belly white; the skin rough, like shagreen, but less so on the belly than on the back; within the mouth, towards the throat, was a very short sort of whalebone; the liver is of a great size, that of the female being the largest, and is melted into a pure and sweet oil, fit for lamps, and much used by the people, who take it to cure bruises, burns, and rheumatic complaints. A large fish will yield eight barrels of oil. These fishes are viviparous, a young one, a foot in length, having been found in the belly of one of them. When they are struck with a harpoon, and wounded, they sling up their tails, and plunge headlong to the bottom, coiling the rope round them, and attempting to disengage themselves from the harpoon, by rolling on the ground. They swim away with such rapidity and violence, that there has been an instance of a vessel of seventy tons having been towed away against a fresh gale; and they will employ the fishers for twelve, and sometimes twenty-four hours, before they are subdued. Pennant's British Zoology, vol. iii. p. 101, &c.

**SHARK, Hammer-headed, *Squalus zygzana***, a fish of the shark kind, called also the *balance-fish*.

It is an extremely singular and remarkable fish, and differs not only from all the other sharks, but from all the fish in the world, in the figure of its head: this is not placed, as in all other fishes, longitudinally, or in a line with the body, but is set on transversely, as the head of a hammer or mallet upon the handle. This is semicircular at the front, and runs to so thin and sharp an edge, that as the fish swims forward with violence, it may cut other fishes, and is terminated at each end by an eye; these are very large, and so placed, that they more conveniently look down than either upward or sideway. In the farther part of the forehead also, near the eyes, on each side, there is a large oblong foramen, serving either for hearing or smelling, or perhaps for both; the mouth is very large, and placed under the head, and armed with four rows of extremely sharp and strong teeth, flat, and serrated at their edges; the tail is composed of

two fins, one vastly larger than the other; the body is rounded and very long, and is not covered with scales, but a thick skin; the back is ash-coloured, and the belly white. Rondelet. de Aquat. p. 549.

It is caught in the Mediterranean, and sometimes in different parts of the ocean. Some authors have called it *zygzana*, and others *libella*; which last answers to the English name of the *balance-fish*.

**SHARK, Picked.** See **ACANTHIAS** and **SQUALUS**.

**SHARK, Long-tailed.** See **SEA-FOX** and **SQUALUS Vulpes**.

**SHARK, Spotted, *Squalus Canicula*** of Linnæus. See **SQUALUS Catulus**.

**SHARK, Lesser spotted,** called the *morgay*, or *rough bound-fish*, *Squalus Catulus* of Linnæus. See **SQUALUS Catulus**.

**SHARK, Smooth, *Squalus Mustelus*** of Linnæus. See **SQUALUS Mustelus**.

**SHARK,** called the *tope*, *Squalus Galeus* of Linnæus. See **SQUALUS Galeus**.

**SHARK,** called the *angel* or *monk-fish*, *Squalus Squatina* of Linnæus. See **SQUALUS Squatina**.

**SHARK River,** in *Geography*, a river of New Jersey, which runs into the Atlantic, N. lat. 40° 10'. W. long. 74° 4'.

**SHARKIND,** a town of Sweden, in East Gothland; 9 miles S.S.W. of Nordkiöping.

**SHARKSTOWN,** a town of Maryland, on the island of Kent; 28 miles S.E. of Baltimore.

**SHARM el Kiman,** or *Sharm el Kaman*, a port on the Red sea, on the coast of Egypt. N. lat. 24° 44'.

**SHARMA,** a town of Arabia, in the province of Hadramaut; 30 miles E.N.E. of Sahar.

**SHARMAGOL,** a town of Persia, in the province of Chorasan; 12 miles S. of Nefa.

**SHARMAK,** a sea-port of Africa, on the Gold Coast; 13 miles W. of Commodo.

**SHARMALIK,** a town of Asiatic Turkey, in the province of Diarbekir; 15 miles S.W. of Ourfa.

**SHAROKIE.** See **SCHON**.

**SHARON,** a town of the province of Maine; 40 miles N. of Portland.—Also, a town of Connecticut; 12 miles N.W. of Litchfield.—Also, a post-town of the state of New York; 25 miles W. of Albany.—Also, a township of Massachusetts; 10 miles S.W. of Boston.—Also, a township of Vermont, on White river; 6 miles N.W. of Norwich.

**SHARP, ABRAHAM,** in *Biography*, an eminent mathematician, mechanist, and astronomer, was descended from a family of Little Horton, near Bradford, in Yorkshire, where he was born about 1651. After he had received a good education, he was put apprentice at Manchester, but being steadily attached to mathematical pursuits, he quitted business and removed to Liverpool. Here he applied with great diligence to his favourite study, and to procure a subsistence he opened a school, where he taught writing and the elements of arithmetic. He next went to London, with the view of associating with Mr. Flamsteed, by whose interest he obtained a profitable employment in the dock-yard at Chatham, where he remained till he was invited to become the assistant of Flamsteed at the Royal Observatory at Greenwich. In this situation he continued to make observations, and had a large share in forming a catalogue of 3000 fixed stars, with their longitudes and magnitudes; their right ascension and polar distance, and the variations of the same, while they change their longitude by one degree. In this employment he injured his health, and was obliged to retire

to his native air, at Horton, where he fitted up an observatory of his own, having constructed a very curious machine for turning all kinds of work in wood and brass. He constructed most of the tools used by joiners, clock-makers, opticians, and mathematical instrument-makers. He manufactured entirely his own telescopes and other astronomical instruments.

He next materially assisted Mr. Flamsteed in calculating most of the tables in the second volume of his "Historia Cœlestis," and made curious drawings of the constellations, which were sent to Amsterdam to be engraved, and though executed by a masterly hand, the originals were said to have exceeded the engravings in beauty and accuracy. In 1689 Mr. Flamsteed completed his mural arc at Greenwich, in which he had been greatly assisted by his friend Mr. Sharp, who had been some time in the observatory as his amanuensis. Mr. Smeaton, in a paper published in the Philosophical Transactions for the year 1786, speaking of this mural arc, says, it may be considered as the first good instrument of the kind, and that Mr. Sharp was the first person who cut accurate and delicate divisions upon astronomical instruments.

In 1717, Mr. Sharp published a work entitled "Geometry Improved," in which he engraved the figures as well as composed the work. This treatise contains 1. A large and accurate table of segments of circles, with the method of its construction, and various uses in the solution of difficult problems. 2. A concise treatise of polyedra, or solid bodies of many bases, both the regular and irregular ones, to which are added twelve new ones, with various methods of forming them, and their exact dimensions in words or species, and also in numbers. In the year 1699 he undertook, for his own private amusement, the quadrature of the circle, deduced from two different series, by which the truth of it was demonstrated to 72 places of figures. Mr. Sharp maintained an epistolary correspondence with the most eminent mathematicians and astronomers of the day; among these were the illustrious Newton, Dr. Halley, and Dr. Wallis. It appears from a great variety of letters which remained after his death, written to him by these celebrated men, that he spared neither pains nor time to promote the interests of real science. Being justly reckoned one of the ablest calculators of his time, his assistance was required by, and freely given to Flamsteed, sir Josias Moore, Dr. Halley, and others, in all difficult calculations. When he quitted Mr. Flamsteed, he retired to Little Horton, in Yorkshire, where he spent the remainder of his days, and where he died in July 1742, in the 91st year of his age. He was of very retired habits, and admitted few visitors, excepting two gentlemen, at Bradford, one a mathematician and the other an ingenious apothecary. Many of his singularities are recorded in the General Biography, and also in Hutton's Mathematical Dictionary, to which the reader is referred.

SHARP, JOHN, archbishop of York, a celebrated divine of the church of England, was the son of a respectable tradesman at Bradford, in Yorkshire, where he was born in 1644. He was admitted of Christ's college, Cambridge, in 1660, and in 1667 he commenced master of arts, and was ordained. He was now appointed private tutor to the four sons of sir Heneage Finch, a station which he occupied about five years, when he obtained, through his patron's recommendation, the archdeaconry of Berkshire. When sir Heneage was raised to the post of keeper of the great seal, he manifested such confidence in the fidelity and judgment of his friend, as to commit to him the scrutiny of the characters of applicants for church livings in the gift of the crown. A sermon which he preached in 1674, re-

flecting upon those who dissented from the church, gave rise to a controversy, in which Dodwell, Baxter, and others engaged. In 1677 he was instituted to the rectory of St. Giles-in-the-Fields, in which parish he resided ten years. Among his parishioners was Richard Baxter, who, though he was himself a preacher on Sunday evenings, was a constant hearer of the rector in the mornings; and these two excellent men, notwithstanding their differences in some points, lived together upon the most friendly terms. In 1679 Mr. Sharp commenced D.D., and in 1681 he was promoted to the deanery of Norwich. On the death of Charles II., to whom he had been a chaplain, he drew up the address of the grand-jury of London to his successor, to whom he was also nominally chaplain. After this he preached against popery, and thus exciting the royal displeasure, he was obliged to quit the metropolis, and reside altogether at his deanery. He employed himself in forming a cabinet of coins, chiefly British, Saxon, and English. Being wearied with his exclusion from his function in London, he presented a very humble petition to the king, in consequence of which, he was allowed to return to his duty in the metropolis, and he was extremely careful never after to give offence, as he had done before. After the abdication of the monarch, Dr. Sharp irritated the adherents to William, by some offensive passages in a prayer and sermon, which he delivered before the house of commons, who at first refused him their accustomed thanks, which, however, were voted afterwards. In 1689, Dr. Sharp was appointed the successor to Dr. Tillotson in the deanery of Canterbury, and he was nominated one of the commissioners for revising the liturgy. At this period several bishops had been deprived of their sees for refusing to take the oaths to William and Mary, and Dr. Sharp might have succeeded to almost any of them, but he refused, not through any scruple of conscience, but on account of his friendship for the persons deprived. When, however, the archbishopric of York became vacant in a different way, he readily accepted the high office, and he was consecrated in July 1691. He filled this exalted station in a manner, which has caused him to be represented as a model of prelatial virtues, and which procured him general respect and esteem. He died at Bath in 1714, in the 69th year of his age. His only writings were sermons, of which were published two volumes, consisting of such occasional discourses as he had printed during his life-time, and five others, that were selected after his decease. He was reckoned an excellent preacher, and his style and doctrine are said to be equally of the standard purity. Biog. Brit.

SHARP, THOMAS, younger son of the preceding, was born in Yorkshire, and admitted of Trinity college, Cambridge, about 1703, when he was of the age of 15. He obtained a fellowship in 1729, and took his doctor's degree the same year. Archbishop Dawes appointed him his chaplain, and in 1720 he was collated to the rectory of Rothbury, in Northumberland. He was afterwards preferred to a prebend in Durham cathedral, and also to the archdeaconry of Northumberland. He died in 1758. Dr. Sharp wrote two dissertations concerning the etymology of the Hebrew words Elohim and Berith—"Discourses on the Antiquity of the Hebrew Tongue and Character." He left a son, Granville, to whose fine character as a genuine English patriot, we shall endeavour to do justice in the next article.

SHARP, GRANVILLE, son of the preceding, a most distinguished philanthropist and friend to the liberties of mankind, was born in the year 1734. He was educated for

the bar, but did not practise at it. When he quitted the legal profession, he obtained a place in the ordnance office, which he resigned at the commencement of the American war; the principles of which were abhorrent from his mind. He now took chambers in the Temple, and devoted himself to a life of study; at the same time, laying himself out for public utility. He first became known to the public in the case of a poor and friendless Negro, of the name of Somerset. This person had been brought from the West Indies to England by a master, whose name we should gladly hand down to the execration of posterity, if it were in our power; and falling into bad health, was abandoned by him as a useless article of property, and turned into the streets, either to die, or to gain a miserable support by precarious charity. In this destitute state, almost, it is said, on the point of expiring on the pavement of one of the public streets of London, Mr. Sharp chanced to see him. He instantly had him removed to St. Bartholomew's hospital, attended personally to his wants, and in a short time had the happiness to see him restored to health. Mr. Sharp now clothed him, and procured him comfortable employment in the service of a lady. Two years had elapsed, and the circumstance almost, and the name of the poor Negro, had escaped the memory of his benefactor, when Mr. Sharp received a letter from a person, signing himself Somerset, confined in the Poultry Compter, stating no cause for his commitment, but intreating his interference to save him from a greater calamity even than the death from which he had before rescued him. Mr. Sharp instantly went to the prison, and found the Negro, who in sickness and misery had been discarded by his master, sent to prison as a runaway slave. The excellent patriot went immediately to the lord mayor, William Nash, esq., who caused the parties to be brought before him; when, after a long hearing, the upright magistrate decided that the master had no property in the person of the Negro, in this country, and gave the Negro his liberty. The master instantly collared him, in the presence of Mr. Sharp and the lord mayor, and insisted on his right to keep him as his property. Mr. Sharp now claimed the protection of the English law, caused the master to be taken into custody, and exhibited articles of peace against him for an assault and battery. After various legal proceedings, supported by him with most undaunted spirit, the twelve judges unanimously concurred in an opinion that the master had acted criminally. Thus did Mr. Sharp emancipate for ever the race of blacks from a state of slavery, while on British ground, and in fact banished slavery from Great Britain. Such an incident could not fail deeply to impress a benevolent mind; and slavery, in every shape and country, became the object of his unceasing hostility. In 1769 he published a work, entitled "A Representation of the Injustice and dangerous Tendency of tolerating Slavery, or of admitting the least Claim of private Property in the Persons of Men in England." Having succeeded in the case of an individual Negro, he interested himself in the condition of the many others, who were seen wandering about the streets of London, and at his own expence collected a number of them, whom he sent back to Africa, where they formed a colony on the river Sierra Leone. He performed a still more essential service to humanity, by becoming the institutor of the "Society for the Abolition of the Slave Trade;" which, after contending against a vast mass of opposition, at length gloriously succeeded, as far as this country was concerned in the horrible traffic.

Mr. Granville Sharp is mentioned in connection with this business, in terms of the highest commendation, by Mr. Clarkson, in his "History of the Abolition of the Slave

Trade." (See vol. i. p. 63—70.) The following short account of him is extracted from the *Edinburgh Review*, vol. xii.

"We think it a duty to mention the name of Mr. Granville Sharp. Regardless of the dangers to which he exposed himself, both in his person and his fortune, Mr. Sharp stood forward in every case as the courageous friend of the poor Africans in England, in direct opposition to an opinion of York and Talbot, the attorney and solicitor-general for the time being. This opinion had been acted upon; and so high was its authority, that, after it had been made public, it was held as the settled law of the land, that a slave, neither by baptism, or arrival in Great Britain or Ireland, acquires freedom, but may be legally forced back to the plantations. Discouraged by judge Blackstone, and several other eminent lawyers, Mr. Sharp devoted three years of his life to the English law, that he might render himself the more effectual advocate of these friendless strangers. In his work, entitled "A Representation of the Injustice and dangerous Tendency of tolerating Slavery in England," published in the year 1769, and afterwards in his learned and laborious "Inquiry into the Principles of Villenages," he refuted the opinion of York and Talbot by unanswerable arguments, and neutralized their authority by the counter opinion of the great lord chief justice Holt, who many years before had decided, that as force could be used against no man in England without legal process, every slave coming into England became free, inasmuch as the laws of England recognized the distinction between person and property as perpetual and sacred. Finally, in the great case of Somerset, which was argued at three different sittings, in January, in February, and in May, of the year 1772, (the opinion of the judges having been taken up on the pleadings,) it is at last ascertained and declared to be the law of the land, that as soon as ever any slave set his foot upon English territory, he became free. Among the heroes and sages of British story, we can think of few whom we should feel a greater glow of honest pride in claiming as an ancestor, than the man to whom we owe our power of repeating with truth,

"Slaves cannot breathe in England; if their lungs  
Receive our air, that moment they are free:  
They touch our country, and their shackles fall."

Similar principles led Mr. Sharp to use his endeavours to restrain the arbitrary practice of marine impressment; and a citizen of London having been carried off by a press-warrant, Mr. Sharp obtained a *habeas corpus* from the court of king's bench, to bring him back from a vessel at the Nore; and by his arguments obliged the court to liberate him. In his political principles he was always the ardent and zealous friend to liberty, and he neglected no opportunity to defend its principles, and assert the rights of the people. He was the warm advocate of "parliamentary reform," and published, in 1778, the second edition of an excellent little work, full of constitutional knowledge and sound reasoning, entitled "A Declaration of the People's natural Right to a Share in the Legislature, which is the fundamental Principle of the British Constitution of State." He was, in 1794, as zealously attached to the cause as he had been twenty years before; though, perhaps, he did not feel himself sufficiently active to engage in it as a partizan, when it was a subject of obloquy. He was not, however, an unconcerned spectator of the dreadful tyranny, which, but for the intervention of an honest English jury, would have overwhelmed the land. He sent, to one of the persons at that time confined in the Tower of London, a copy of the  
work

work referred to, with assurances of a readiness to do any thing in his power to stem the torrent setting in against the liberties of the country.

Mr. Sharp's plan of reform recommended to the public, was founded on the earliest principles and practices of the British constitution. He proposed to restore the ancient *tithings, hundreds, &c.*; and the whole body of the people were to form a national militia, each thousand to constitute a regiment, the alderman or magistrate to be the colonel; and each hundred to constitute a company, the constable of each for the time being to be their captain. So many of the thousands to be summoned once in every year, by their magistrate, as would have a right to vote in their respective hundreds, before the constable, in the choice of their part of the representative legislature. Mr. Sharp has shewn that the division of this kingdom into tythings and hundreds was instituted by the immortal Alfred; that such a division is consistent with the most perfect state of liberty that man is capable of enjoying, and yet fully competent to answer all the purposes of mutual defence, to secure the due execution of the laws, and maintain public peace.

Mr. Sharp was educated in the principles of the established church, and through life shewed a warm attachment to them. He always, even at the close of life, had a thorough dread of Popery, but was candid and liberal to Protestant dissenters of all parties. His zeal for the established religion of the country led him to recommend an episcopal church in America; and he introduced the first bishops from that country to the archbishop of Canterbury for consecration.

Mr. Sharp died in July 1813, and like Cato, though advanced to the age of 79, he pursued his studies with all the ardour of youth. He was an able linguist, deeply read in theology, and was well acquainted with the scriptures in the original tongues. He was pious and devout, without gloom, strictly moral and temperate, a great lover of music, and cheerful in conversation. His services to humanity were very distinguished, and few persons in private life have deserved a higher or more honourable commemoration.

As a writer, his pieces are very numerous. From these we learn that he was a believer in the doctrines as set forth in the articles of the church, as that of original sin, the existence and operations of the devil on the human mind, and of the Athanasian mystery of the Trinity. He also, from studying the book of Revelation, fully expected the commencement of the *Millenium*, or personal reign of Christ on earth, in the spring of 1811; but he lived long enough to see his error. He possessed a very extensive library, in which the theologian, lawyer, classical scholar, politician, antiquary, and orientalist, might find almost every thing of which they could stand in need; and his collection of bibles was esteemed the best in the kingdom.

The principal works of Mr. Sharp, besides those already mentioned, are "Remarks on several very important Prophecies;" "Remarks on the Uses of the definitive Article in the Greek of the New Testament, containing many new Proofs of the Divinity of Christ," &c. This occasioned "Six Letters" to be addressed to him, in vindication of his theory; and also "Six more Letters, &c." by Gregory Blunt, esq., which is a work of great talent, profound learning, and masterly wit. It has long since been out of print, and the author is probably known only to two or three persons; the designation Blunt being assumed to conceal the real name. Mr. Sharp's last work was entitled "Remarks on the 68th Psalm, addressed to the Consideration of the House of Israel." Monthly Mag. Gentle-

man's Mag. Edin. Rev. Clarkson's Hist. of the Abolition of the Slave Trade.

SHARP, SAMUEL, an able and distinguished surgeon in the middle of the last century, was a pupil of the celebrated Chefelden, and afterwards studied his profession with great zeal at the hospitals of Paris. He is said to have commenced his profession rather late in life; nevertheless, after settling in London, and obtaining an appointment as surgeon of Guy's hospital, his genius and assiduity soon obtained for him a high degree of celebrity, and extensive practice. He was elected a fellow of the Royal Society, and a foreign member of the Academy of Surgery at Paris; and he contributed to the improvement of his art by two valuable publications, which passed through many editions, and were translated into several foreign languages. The first of these was "A Treatise on the Operations of Surgery, with a Description and Representation of the Instruments; and an Introduction on the Nature and Treatment of Wounds, Abscesses, and Ulcers;" first printed in 1739. Our edition, printed in 1751, is the sixth. The second work was entitled "A critical Inquiry into the present State of Surgery;" first printed, we believe, in 1750. Our edition of 1761 is the fourth. See ELOY Dict. Hist. de la Med., and Sharp's Works.

SHARP, in *Music*, is a chromatic sign, marked thus, ♯; and elevates the note before which it is placed half a tone, without changing its name or place on the staff.

A sharp on a line or space, at the beginning of a movement, affects all the notes of the same name throughout the piece, contradicted by a natural, ♮. See NATURAL.

An accidental sharp affects no note beyond the single bar in which it occurs; but it always, when accompanied by a base or lower part, implies a new modulation, except in minor keys, the sharp to the seventh of the key, which is a thing of course.

In the key of C ♯ with a sharp third, there are seven sharps at the clef, which implies that every note in the scale is elevated a semitone above its usual pitch.

In this key, an accidental sharp is marked by a double sharp x, usually called a *diesis*, or enharmonic sharp; which see.

SHARP the *Bow-line*, in *Sea Language*. See BOWLING.

SHARP Nails. See NAIL.

SHARPE, GREGORY, in *Biography*, a learned divine, was born in Yorkshire in the year 1713. He received his education first at Westminster school, and afterwards at Aberdeen, under the learned Blackwell. Upon his entering orders he became minister of St. Margaret's chapel, Westminster; after this, he was appointed chaplain to the king, and master of the Temple. He was also elected a fellow of the Royal and Antiquarian Societies; and died in 1771. He united to great learning a taste for the fine arts, and etched several plates in the edition of Dr. Hyde's Syntagma. His own works are, 1. A Review of the Controversy about the Meaning of the Demoniaes in the New Testament. 2. A Defence of Dr. Clarke against Leibnitz. 3. Two Dissertations upon the Origin of Languages, and the Power of Letters; with a Hebrew Lexicon. 4. A Dissertation on the Origin and Structure of the Latin Language. 5. Two Arguments in Defence of Christianity. 6. Translation of Holberg's Introduction to Universal History. 7. Sermons.

To which is prefixed a biographical preface, from which the foregoing facts have been extracted.

**SHARPING CORN**, a customary present of corn, which, at every Christmas, the farmers in some parts of England make to their smith, for sharpening their ploughing-irons, harrow-tines, &c.

**SHARPLING**, in *Ichthyology*, the English name of the gattersteus. See *STICKLE-Back*.

**SHARPSBURG**, in *Geography*, a town of America, in Maryland; 69 miles N.W. of Baltimore.

**SHARUM**, a town of Arabia, in Hadramaut; 15 miles S.W. of Keschim.

**SHARUT**, **SHAHNAT**, or *Sharoot*, a small town of Persia, in Alterabad, called also Biltan, is surrounded in some parts with a slight earthen wall. The houses, from a want of wood, are built of unburnt bricks, and covered with a flat arch of the same materials. In its vicinity are seen many people, whose noses, fingers, and toes have been destroyed by the frost, which is said to be feverer at this place than in any part of Persia. This town, with its dependencies, yields a revenue of 1969 tomans. The position of the town is determined by two routes, one from Tehraun and the other from Tarshith.

**SHASAD**, or **SHAZADBARY**, a town of Hindoostan, in the circar of Sumbul; 16 miles S. of Sumbul.

**SHASAVA**, a town of Hindoostan; 18 miles S. of Agra.

**SHASH, AL.** See **TASHKUND**.

**SHASHTI**, in *Mythology*, a name of the Hindoo goddess *Parvati*; which see.

**SHASK**, in *Geography*, a town of Hindoostan, in Baglana; 15 miles S. of Bahbelgong.

**SHASSAIR**, a town of Africa, in Biledulgerid; 7 miles N. of Fighig.

**SHASTAH**, **SHASTER**, or *Sastra*, which latter is said to be the correct spelling and pronunciation, the name of a sacred book, in high estimation among the idolaters of Hindoostan, containing all the dogmas of the religion of the Bramins, and all the ceremonies of their worship, and serving as a commentary on the Vedam.

The word is derived from a root signifying *to ordain*, and means generally an ordinance, and particularly a sacred ordinance delivered by inspiration: properly, therefore, the word is applicable chiefly to sacred literature.

The term *Shaster* denotes *science* or *system*; and is applied to other works of astronomy and philosophy, which have no relation to the religion of the Indians. None but the Bramins and rajahs of India are allowed to read the Vedam; the priests of the Banians, called *Shuderers*, may read the *Shaster*; and the people, in general, are allowed to read only the *Paran* or *Pouran*, which is a commentary on the *Shaster*.

The *Shaster* is divided into three parts; the first containing the moral law of the Indians; the second, the rites and ceremonies of their religion; and the third, the distribution of the people into tribes and classes, with the duties pertaining to each class.

The principal precepts of morality contained in the first part of the *Shaster*, are the following: that no animal be killed, because the Indians attribute souls to brute animals as well as to mankind; that they neither hear nor speak evil, nor drink wine, nor eat flesh, nor touch any thing that is unclean; that they observe the feasts, prayers, and washings, which their law prescribes; that they tell no lies, nor are guilty of deceit in trade; that they neither oppress nor offer violence to one another; that they celebrate the

solemn feasts and fasts, and appropriate certain hours of ordinary sleep to cultivate a disposition for prayer; and that they do not steal, or defraud one another.

The ceremonies contained in the second part of the *Shaster*, are such as these: that they wash often in the rivers, hereby obtaining the pardon of their sins; that they mark their forehead with red, in token of their relation to the Deity; that they present offerings and prayers under certain trees, set apart for this purpose; that they pray in the temple, make oblations to their pagodas, or idols, sing hymns, and make processions, &c.; that they practise pilgrimages to distant rivers, and especially to the Ganges, there to wash themselves, and make offerings; that they make vows to particular saints, according to their respective departments; that they render homage to the Deity, at the first sight of the sun; that they pay their respect to the sun and moon, which are the two eyes of the Deity; and that they treat with particular veneration, those animals that are deemed more pure than others, as the cow, buffalo, &c. because the souls of men have transmigrated into these animals.

The third part of the *Shaster* records the distribution of the people into four classes; the first being that of the Bramins, or priests, appointed to instruct the people: the second, that of the Kutteris, or nobles, who are the magistrates: the third, that of the Shudderis, or merchants: and the fourth, that of the mechanics. Each person is required to remain in the class in which he was born, and to pursue the occupation assigned to him by the *Shaster*. According to the Bramins, the *Shaster* was imparted by God himself to Brahma, and by him to the Bramins, who communicated the contents of it to the people.

Modern writers have given us very different accounts of the antiquity and importance of the *Shaster*. Mr. Holwell, who had made a considerable progress in the translation of this book, apprehends, that the mythology, as well as the cosmogony of the Egyptians, Greeks, and Romans, were borrowed from the doctrines of the Bramins contained in it, even to the copying of their exteriors of worship, and the distribution of their idols, though grossly mutilated and adulterated. With respect to the Vedam and *Shaster*, or scriptures of the Gentoos, this writer informs us that Vedam, in the Malabar language, signifies the same as *Shastah* in the Shanferit; and that the first book is followed by the Gentoos of the Malabar and Coromandel coasts, and also of the island of Ceylon. The *Shastah* is followed by the Gentoos of the provinces of Bengal, and by all the Gentoos of the rest of India, commonly called India Proper, along the course of the rivers Ganges and Jumna to the Indus. Both these books, he says, contain the institutes of their respective religion and worship, as well as the history of their ancient rajahs and princes; often couched under allegory and fable: their antiquity is contended for by the partisans of each; but he thinks, that the similitude of their names, idols, and great part of their worship, leaves little room to doubt, nay, plainly evinces, that both these scriptures were originally one. He adds, if we compare the great purity and chaste manners of the *Shastah*, with the great absurdities and impurities of the Vedam, we need not hesitate to pronounce the latter a corruption of the former.

With regard to the high original of these scriptures, the account of the Bramins is chiefly as follows. Brahma, *g. d.* Mighty Spirit, about four thousand eight hundred and sixty-six years ago, assumed the form of man, and the government of Hindoostan. He translated the divine law (designed for the restoration of mankind, who had offended in a pre-existent state,

state, and who are now in the last scene of probation, to the dignity from which they were degraded,) out of the language of angels into the well-known Shanferit language, and called his translation the "Chartah Bhade Shastah" of Birmah, or the Six Scriptures of the Divine Words of the Mighty Spirit. He appointed the Bramins, deriving their name from him, to preach the word of God; and the doctrines of the Shastah were accordingly preached in their original purity a thousand years. About this time there was published a paraphrase on the Chartah Bhade: and about five hundred years afterwards, a second exposition, called "Aughtorrah Bhade Shasta," or eighteen Books of Divine Words, written in a character compounded of the common Hindoostan and the Shanferit. This innovation produced a schism among the Gentoos; on which occasion, it is said, those of Coromandel and Malabar formed a scripture of their own, which they pretended to be founded on the Chartah Bhade of Birmah, and called it the Vedam of Birmah, or Divine Words of the Mighty Spirit. The original Chartah Bhade was thrown aside, and, at length, wholly unknown, except to a few families, who can still read and expound it in the Shanferit character. With the establishment of the Aughtorrah Bhade, and Vedam, which, according to the Gentoos account, is three thousand three hundred and sixty-six years ago, their polytheism commenced; and the principles of religion became so obscure, and their ceremonies so numerous, that every head of a family was obliged to keep a Bramin, as a guide both in faith and practice. Mr. Holwell is of opinion, that the Chartah Bhade, or original scriptures, are not copied from any other system of theology, promulgated to, or obtruded upon mankind. The Gentoos do not attribute them to Zoroaster; and Mr. Holwell supposes, that both Zoroaster and Pythagoras visited Hindoostan, not to instruct, but to be instructed.

From the account of Mr. Dow we learn, that the books which contain the religion and philosophy of the Hindoos, are distinguished by the name of Bedas; that they are four in number, and, like the sacred writings of other nations, said to be penned by the divinity. Beda, he says, in the Shanferit language, literally signifies *science*; and these books treat not only of religion and moral duties, but of every branch of philosophic knowledge. The Bramins maintain, that the Bedas are the divine laws, which Brimha, at the creation of the world, delivered for the instruction of mankind; but they affirm, that their meaning was perverted in the first age by the ignorance and wickedness of some princes, whom they represent as evil spirits, who then haunted the earth. The first credible account we have of the Bedas is, that about the commencement of the callug, of which era the year 1768 was the 4886th year, they were written, or rather collected, by a great philosopher, and reputed prophet, called Beas Muni, or Beas the Inspired.

The Hindoos, says Mr. Dow, are divided into two great religious sects: the followers of the doctrine of Bedang, which is the original Shaster, or commentary upon the Bedas; and those who adhere to the principles of the Neadirsen. The original Shaster is called Bedang, and is a commentary upon the Bedas. This, he says, is erroneously called, in Europe, the Vedam. It is ascribed to Beas Muni, and said to have been revised some years after by one Serrider Swami, since which it has been reckoned sacred, and not subject to any farther alterations. Almost all the Hindoos of the Deccan, and those of the Malabar and Coromandel coasts, are of this sect. The followers of the Bedang Shaster do not allow that any physical evil exists; they maintain that God created all things perfectly good, but that man, being a free agent, may be guilty of moral evil,

which may be injurious to himself, but can be of no detriment to the general system of nature. God, they say, being perfectly benevolent, never punished the wicked otherwise than by the pain and affliction which are the natural consequences of evil actions; and hell, therefore, is no other than a consciousness of our evil.

The Neadirsen Shaster is said to have been written by a philosopher called Goutam, near four thousand years ago. The Bramins, from Mr. Dow's account of their sacred books, appear to believe invariably in the unity, eternity, omniscience, and omnipotence of God; and the polytheism, of which they have been accused, is no more than a symbolical worship of the divine attributes, which they divide into three classes. Under the name of Brimha, they worship the wisdom and creative power of God; under the appellation of Bishen, his providential and preserving quality; and under that of Shibah, that attribute which tends to destroy.

According to M. de Sainte-Croix, the Shasta, however extolled in Europe with respect to its antiquity, is posterior to the Vedam, being no more than the explication of it. Holwell's Interesting Historical Events, &c. 8vo. Dow's History of Hindoostan, 4to. 1768. L'Ézour Vedam, &c. by M. de Sainte-Croix, 12mo. Paris, 1779. See GENTOOS, SHANSERIT, and VEDAM.

Six Sastras are commonly described as of superior sanctity, and are called the *proper* Sastras:—in these are comprised the four Vedas, the eighteen Puranas, commentaries on the Vedas, called Upaveda, and others. (See VEDA, and PURANA.) The Sudra, or lowest of the four classes of Hindoos, are not permitted to study these six Sastras, as being too holy for such profane contemplation. (See SUDRA.) As noticed under the article RAMAYANA, that book is reckoned too sublime for the perusal of so inferior a class. The Sudra may *hear* it read. An ample field, however, remains for them in the study of profane literature, comprised in a multitude of popular books, which correspond with the several Sastras, and abound with beauties of every kind. All the tracts on medicine must indeed be studied by the Vaidyas, or those who are born physicians; and this profession is confined chiefly to the Sudras. The Vaidyas are said to have often more learning than many Bramins, with far less pride than any. They are usually poets, grammarians, rhetoricians, &c. and may be esteemed in general among the most amiable and virtuous of the Hindoos. See VAIDYA.

The word Sastra is, however, applied more extensively than the above account may seem to imply. For instance, a collection of tracts on arts and manufactures, is called Silpi Sastra. The name of Niti Sastra is given to a system of ethics. The Dertana Sastra is indeed one of the six superior, and comprises an explanation of the principles of the six philosophical schools; a brief notice of which is given under the article PHILOSOPHY of the Hindoos. An analysis of this work would shew that many of its theories are either the source of similar doctrines propounded in later times in Greece, or borrowed from the same source with them. Other collections of tracts, and some separate works, bear also the denomination of Sastra; and it is sometimes rather vaguely applied. A Brahman deeply versed in sacred literature has the honourable title of Sastrî added to his name; equivalent to our *clericus*. Sometimes he is distinguished by it alone, and called *the Sastrî*. There is also the Dherma Sastra, a body of ethics and ritual observances; the Agama Sastra, or occult ordinances. This latter has been suspected to have some reference to the Ogham of the west. See OGHAM, and O'M.

*Saſtri*, which was omitted in its proper place, is a name for the Hindoo deity Budha, or Boodh. The name ſignifies wiſdom, or a wife man; and is ſtill applied to, or aſſumed by, individuals, eſpecially Bramins, who are ſuppoſed to have acquired an extraordinary degree of learning or wiſdom. As all profitable wiſdom is preſumed to be comprized in the *Saſtra*, or ſacred books, the title of *Saſtri* is thence derived. It is ſometimes appended ſimilarly to the ſcholar's name; and he is at others called the *Saſtri*, or *Saſtri ſahib*,—Mr. *Saſtri*.

SHASUMAN, in *Geography*, a town of Perſia, in the province of Mazanderan; 30 miles E. of Eſterabad.

SHAT-EL-AMAAR, a name given by the Arabs to the Tigris.

SHAT-EL-DEAAL, a river which runs from the north, and enters the Tigris near Bagdad.

SHAT-EL-DEGELA, a river or canal, ſo called by the Arabs, which communicates with another named *Shat-el-Hie*, which is a branch of the Tigris.

SHAT-EL-FRAATE, a name given by the Arabs to the Euphrates.

SHAT-KRATU, in *Mythology*, one of the names of the Hindoo Indra, regent of the firmament. It means the hundred ſacrifices; that is, he to whom a hundred ſacrifices are offered; or rather, perhaps, he who has offered them. Indra, it is ſabled, obtained his preſent dignity by the great ſacrifice of a hundred horſes. An offering of a horſe is called *Aſwamedha*, and is attended with infinite trouble and expence, as laid down in the Hindoo rituals. See *INDRA*, *NARAMEDHA*, and *RHEMBA*.

SHATNUF, in *Geography*, a town of Egypt, on the right bank of the Nile; 9 miles N. of Cairo.

SHATOOR, a town of Hindooſtan, in Madura; 20 miles N.N.W. of Coilpetta.

SHATORE, a town of Hindooſtan, in Madura; 12 miles N.E. of Coilpetta.

SHAT-UL-ARAB, one of the nobleſt rivers in the Eaſt, formed by the combined ſtreams of the Euphrates and Tigris. The union of theſe ſtreams takes place near Korna, or Corny, which is one of the three Apameas, built by Seleucus in honour of his firſt wife, Apama. On the weſtern bank of this river, and 70 miles from its mouth, in N. lat.  $31^{\circ} 30'$ , is ſituated the city of Buſſora or Baſra; and the river is navigable as far as the city for ſhips of 500 tons burthen. The city is ſometimes ſo completely deluged by the river, that it appears like an iſland in the middle of a lake. The combined ſtream of the *Shat-ul-Arab* has generally been thought to enter the Perſian gulf by a variety of mouths: but the fact is, that this noble river has, at this time, only one mouth, and probably never had any other. The iſland, or delta, between the *Shat-ul-Arab* and the *Bamifhern* (the ancient *Meſena*) was formerly included in the pachalic of Bagdad; but having been conquered by Sheik Solyman from the Turks, has remained in the poſſeſſion of his ſucceſſors. This is a low and fertile tract; the northern parts of which, towards the *Hafur*, are interſected by a number of canals, and are in a tolerable ſtate of cultivation. Extenſive ruins are viſible in many places, and the borders of the *Shat-ul-Arab*, as far down as Chubda, are covered with date-trees. The river "*Shat-el-Ajew*," ſignifying in Arabic a river of Perſia, diſcharges itſelf on the Perſian ſide into the *Shat-ul-Arab*, near Margill.

SHATZAM, a town of Perſia, in the province of Mekran; 210 miles S.E. of Arokhage.

SHAVAKAT, a town of Turkeſtan, on the Sirr; 20 miles S. of Taſhkund.

SHAUBACO, a town of Egypt, on the left bank of the Nile; 16 miles S. of Cairo.

SHAVE GRASS, in *Botany*. See *EQUISETUM*.

SHAVING-IRONS, among *Gardeners*, tools to keep a garden free from weeds, otherwiſe called *edging-irons*.

SHAVINGS, HORN, in *Agriculture*. See *MANURE*.

SHAUL, or SHAWL, an article of female drefs, much prized in the Eaſt, and now well known in England. As the ſhaws all come from Caſhmere, or Cachemir, it was generally concludcd, that the materials from which they were fabricated was of the growth of that country. It was ſaid to be the hair of a particular goat, and the fine under hair from a camel's breast; but we now certainly know that it is the produce of a Thibet ſheep. Bernier relates, that in his time, ſhaws made for the great omrahs of the Thibetian wool, coſt a hundred and fifty rupees; whereas thoſe made of the wool of the country never coſt more than fifty. For an account of their manufacture and value, ſee *CASHMERE*.

SHAVOYA, or CHAVOYA, in *Geography*, a province of the empire of Morocco, ſituated to the S. of the kingdom of Fez, and W. of Tedla; inhabited by mountaineers addicted to robbery and violence. Towards the latter end of the laſt century reſuſing to pay tribute to the emperor, Muley Iſmael, he marched an army, which, ſurrounding their ſtrong holds on the mountains, compelled them to flight, leaving their wives and children, who were put to the ſword, and the plunder diſtributed among the ſoldiers.

SHAUR, a ſmall iſland in the Red ſea. N. lat.  $27^{\circ} 20'$ . E. long.  $34^{\circ} 58'$ .

SHAUS. See *CHAUS*.

SHAVUNGUNK, a mountain of New York; 20 miles S. of Kingſton.

SHAW, THOMAS, in *Biography*, was born at Kendal in or about the year 1692. He was educated at the grammar-ſchool of that town, and in 1711 was admitted of Queen's college, Oxford. Soon after he had taken orders, he was appointed chaplain to the Engliſh factory at Algiers, in which ſtation he remained ſeveral years, making uſe of the opportunity which it afforded of travelling into various parts of Barbary, and into Egypt. In 1727 he was elected fellow of his college, in 1733 he commenced D.D., and in the following year he was elected a member of the Royal Society in London. In 1738 he publiſhed his "*Travels, or Observations on ſeveral Parts of Barbary and the Levant*," to which a ſupplement was added in 1746; and about ten years afterwards the whole appeared in a ſecond edition, with conſiderable improvements. Few books of the kind ſtand higher in reputation than *Dr. Shaw's Travels*, which contain many learned diſſertations reſpecting the countries which he had viſited, with divers remarks on their manners and cuſtoms, and valuable obſervations in natural hiſtory. They have been regarded as particularly uſeful in illuſtrating the ſcriptures by compariſons between the ancient and modern ſtate of the eaſtern regions. *Dr. Shaw*, on his return from his travels, brought back a large collection of dried plants. He preſented to the univerſity of Oxford ſome relics of antiquity which he had collected, of three of which engravings were made in the "*Marmora Oxoniensis*." In the year 1740 he was choſen principal of St. Edmund's Hall, and was at the ſame time preſented to the vicarage of Bramley in Hampſhire. Soon after the regius profeſſorſhip was conferred upon him, which he held till his death, in 1751. His *Travels* have been translated into various modern languages. An attack was made on them by *Dr. Pocock*, which led the author to defend them in his ſupplement, and in a letter of *Dr. Clayton*, biſhop of Clogher.

SHAW, PETER, a physician, and contemporary of the former, was the author of several works, which enjoyed a considerable reputation in their day. His first publication was entitled "New Practice of Physic," in two volumes, and first printed in 1726: it contained a brief description of diseases and the methods of treating them. His next work was an "Enquiry into the Virtues of Scarborough Spaw Waters," which he visited during the season; it was printed in 1734. In the same year he published also "Chymical Lectures publicly read in London 1731, 1732, and Scarborough 1733." This was deemed a scientific and valuable work, and was translated into French. He published some minor works, "A Portable Laboratory," 1731; "On Scurvy," 1736; "Essays in Artificial Philosophy," 1731; "On the Juice of the Grape," 1724; and he edited the "Dispensatory of the College of Physicians of Edinburgh," in 1727. See Eloy Dict. Hist. de la Méd.: and the works mentioned.

SHAW, GEORGE, the younger of two sons of the reverend Timothy Shaw, was born December 16th, 1751, at Berton, in Buckinghamshire, of which place his father was vicar. He shewed, at a very early age, a great propensity to study, and when he was only four years old, instead of following the amusements common to young children, he usually entertained himself with books, or by the side of ditches and rivulets catching insects, and taking them home, and would spend all his leisure time in watching their motions and examining their structure. He was educated entirely by his father, and before he was fourteen years of age, his proficiency was such as allowed him to enter with great advantage upon a course of college studies. In 1765 he was entered at Magdalen-hall, Oxford, where he was no less distinguished by the regularity of his conduct, than by an uncommon diligent application to his studies. In 1769 he was admitted to the degree of B.A. and in May 1772 to that of M.A. In order that he might assist his father in his clerical duties, he took orders, and was ordained deacon in 1774, at Buckden, by Dr. Green, bishop of Lincoln, and regularly performed the duty at Stoke and Buckland, two chapels, each three miles apart from the mother church. As soon as an opportunity offered, he laid aside his theological career, which was never quite congenial to his mind, and went to Edinburgh, to qualify himself for the profession of physic. Having attended the lectures of Black, Cullen, and other eminent professors for three years, he returned to Oxford, where he was appointed deputy botanical lecturer. In this office he acquired much celebrity. He had been appointed to his office by Dr. Sibthorp, the botanical professor, who was then upon the eve of setting out upon his travels into Greece. (See SIBTHORP.) Upon the death of this gentleman, Dr. Shaw became candidate for the vacant professorship, in which he would unquestionably have been successful, had not an old statute been found, which prohibits a person in orders from filling the office. In 1787 he was admitted to the degrees of bachelor and doctor of medicine: it appears that at this time he had removed from Magdalen-hall to Magdalen college. In the same year he removed to London, where he practised as a physician. Shortly after this, several gentlemen, distinguished for their attachment to the study of, and eminent for their acquirements in natural history, established a society for the advancement of this science, under the denomination of the Linnæan Society. Dr. (now sir James) Smith was elevated to the presidency, and Dr. Shaw was nominated one of the vice-presidents. To the Transactions of this Society Dr. Shaw contributed the following papers. "Description of the *STYLEPHORUS Cordatus*," which see; "Description of the

CANCER *Stagnalis*;" "Remarks on the *SCOLOPENDRA Electrica* and *SCOLOPENDRA Subterranea*;" "A Note to Mr. Kirby's Description of the new Species of *Hirudo*;" "Account of a minute Ichneumon;" "Description of the Species of *Mycteria*;" "Description of the *Mus Burlarius*, and *Tubularia Magnifica*."

Dr. Shaw at this period delivered a course of lectures at the Leverian Museum, and never failed, as well before, as after, that rich and magnificent collection was removed from Leicester Fields, to attract very large and scientific audiences. In 1789 Dr. Shaw began to publish "The Naturalist's Miscellany," which came out in monthly numbers, and continued to his decease, when 286 parts had been published, and, according to the biography of the author given in the Gentleman's Magazine, a posthumous number, with an index, was to terminate the work, which is described as a most beautiful and extensive production, comprising, in 1064 plates, figures of the more curious and remarkable productions of the three kingdoms of nature, more particularly of the animal kingdom, with descriptions in Latin and English. In this year Dr. Shaw was elected a fellow of the Royal Society, and in 1790 he projected a work in 4to. entitled "Speculum Linnæum; or Linnæan Zoology," but it probably did not promise success, as a single number only appeared. In 1791 Dr. Shaw became a candidate for the office of a librarian in the British Museum, and his qualifications, which were of the first order, procured him the appointment of assistant keeper of the natural history. He now quitted the duties of physician, and devoted himself entirely to researches in natural science. Between the years 1792—6, appeared the following work; "Musæi Leveriani explicatio Anglica et Latina, opera et studio Georgii Shaw, M.D. F.R.S. Adduntur figuræ elegantur sculptæ et coloratæ. Impensis Jacobi Parkinson." In 1794 Dr. Shaw, in conjunction with Dr. Smith and Mr. Sowerby, engaged in a splendid publication, illustrative of the accessions which had been made to natural science on the shores of New Holland. The animals peculiar to that country were described by Dr. Shaw in a work entitled "The Zoology of New Holland;" the figures were delineated by Mr. Sowerby; and the botanical part was written by Dr. Smith, and published under the title of "The Botany of New Holland."

Sixty large plates published by Miller, the editor of the Gardener's Dictionary, under the title of "Various Subjects in Natural History, wherein are delineated Birds, Animals, and many curious Plants," being judged defective from want of letter-press, Dr. Shaw supplied the deficiency in a work entitled "Cimelia Phytica: Figures of rare and curious Quadrupeds, Birds, &c. together with several most elegant Plants, engraved and coloured from the Subjects themselves: with Descriptions by George Shaw, M.D. F.R.S."

In the year 1800, Dr. Shaw began his great work, entitled "General Zoology, or Natural History, with Plates from the best Authorities, and most select Specimens." This work had proceeded to the eighth volume during the life-time of the author, and a ninth was left ready for the press. In this work he intended to comprise the whole of the history of the animal world. It began with quadrupeds, and had proceeded through fishes, amphibia, insects, and part of the birds. The Linnæan arrangement, with occasional variations, has been pursued throughout.

In the years 1806 and 1807, Dr. Shaw delivered a course of zoological lectures, which were published in 1809 in two large volumes 8vo. In the first nine lectures the author has compressed the substance of what he had delivered in the General Zoology, and in the three remaining lectures is

a sketch of what, had his life been spared, he intended to accomplish in completing the *General Zoology*. In 1807, upon the death of Dr. Gray, keeper of Natural History in the British Museum, Dr. Shaw was promoted to that office. An abridgment of the Transactions of the Royal Society was begun in 1809, of which the department of natural history fell to the lot of Dr. Shaw. It is said he abridged 1500 distinct articles, which he rendered still more interesting than the originals, by the insertion of Linnæan and specific names, and by occasional annotations, and considerable references to subsequent authors of most celebrity, who had treated on these subjects. This was the last work in which he engaged. His time was wholly occupied upon the "Naturalist's Miscellany" and the "General Zoology," when death terminated his active and very useful life on the 22d of July, 1813, in the 62d year of his age. His illness was but of a few days' continuance; his senses and his recollection only forsook him with his breath. He died, as he had lived, with philosophic composure and serenity of mind, which neither the acute pains which he endured, nor the awful change which he was well aware he was about to experience, could in any degree disturb.

"As few men have left behind them a character more estimable, his name will be transmitted to posterity among those who give lustre to their age and country, who do honour to human nature by their virtues, and who contribute to the advancement of science, and the interests of literature, by their superior talents. Endowed by nature with considerable intellectual parts, and these improved by assiduous cultivation, he acquired a vast stock of general knowledge. His extensive information was treasured up without confusion, applied in his works with discernment, and communicated to every enquirer with cheerfulness and freedom." *Gentleman's Magazine*, 1813, p. 290.

SHAW, STUBBING, a divine and antiquary, was born at Stowe, in Staffordshire, in 1762, and educated first at Repton school, and afterwards at Queen's college, Cambridge, where he took his degrees and obtained a fellowship. In 1787 he made a tour in the Highlands of Scotland, of which he published an account without his name. In the following year he made another tour in the west of England, an account of which he also published. In 1789 he commenced, in conjunction with a friend, a periodical publication, called *The Topographer*, chiefly consisting of extracts made from curious books and MSS. in the British Museum. This work was discontinued in about two years. He next undertook the "History of Staffordshire," of which the first vol. in folio, was published in 1798; in 1801 the first part of the second volume was given to the public, and he died in 1803.

SHAW, in our *Old Writers*, a grove of trees, or a wood.

SHAW Fowl, an artificial fowl made for fowlers to shoot at.

SHAW'S Island, in *Geography*, a small island in the North Pacific ocean, at the entrance of Cook's Inlet. N. lat. 59°. E. long. 207° 16'.

SHAWABAD, a town of Hindoostan, in the circar of Rantampour; 35 miles S. of Suifopour.

SHAWANEE, a town of America, in the county of Randolph, and territory of Illinois, containing 830 inhabitants.

SHAWANESE, the denomination of a tribe of Indians who inhabit Louisiana, on the Mississippi and St. Francis. The number of warriors is 300; that of the inhabitants 800; their trade requires 1000 dollars of merchandise; the value of their returns is 3000; their commerce is carried on in their villages or settlements. The Indians

of this tribe have four towns on the Tallapoossee river. By the treaty of peace, Aug. 3, 1795, the United States agreed to pay this tribe a sum in hand, and 1000 dollars annually for ever in goods. They inhabit on the Scioto river, and a branch of the Muskingum, and have their hunting grounds between Ohio river and lake Erie. They are generally of a small size, rather handsome in their features, and a cheerful crafty people. Counselling among the elder, and dancing among the young men and women, take up a great part of their time.

SHAWANGUNK, a post-town in Ulster county, New York; containing 2809 inhabitants; 20 miles from Goshen and 12 from New Paltz.

SHAWGUNGE, a town of Hindoostan, in Oude, on the left bank of Dewah, opposite to Fyzabad.

SHAWGUR, a town of Hindoostan, in Allahabad; 32 miles N. of Gazypour.

SHAWIA, in *Botany*, received its name in honour of the celebrated oriental traveller, Dr. Thomas Shaw, who has given a catalogue, in alphabetical order, accompanied with rude plates, of the rarer plants, observed by him in Barbary, Egypt, and Arabia. The species amount to 632, and the catalogue is enriched with several synonyms, as well as occasional descriptions and remarks. His dried specimens are preserved at Oxford. The orthography of the name is attended with difficulty to foreigners, our *w* being as unmanageable to them, as their multiplied consonants are to us. Some of them blunder into *Scharvia*, *Shaavia*, or *Shavia*. Perhaps the latter might be tolerated, were it not for the ludicrous ambiguity of *Shavia* itself, applied by facetious Oxonians to the above famous traveller and his namesakes.—*Forst. Gen. t. 48. Prodr. 58. Schreb. Gen. 595. Mart. Mill. Dict. v. 4. Juss. 180. Lamarek Dict. v. 7. 148.*—Class and order, *Syngenesia Monogamia*, Forster. *S. Polyzamia-segregata*, Schreb. *Nat. Ord. Composita discoidea*, Linn. *Corymbifera*, Juss.

Gen. Ch. Cal. Perianth imbricated, cylindrical, of five or six oblong scales; the three innermost longest, and nearly equal. Cor. of one petal, funnel-shaped, short; limb in five linear spreading segments. Stam. Filaments five, capillary; anthers united into a cylindrical tube. Pist. Germen oblong, below the corolla, superior with respect to the calyx; style thread-shaped, longer than the corolla; stigma divided, spreading. Peric. none, except the unchanged perious calyx. Seed solitary, oblong. Down capillary, woolly at its base. Recept. naked.

Ess. Ch. Calyx imbricated, single-flowered. Corolla tubular, regular. Seed-down capillary, woolly at its base.

1. *S. paniculata*. Forst. Prodr. n. 1.—Native of New Zealand. We have seen no specimen of this plant. The younger Linnæus, in his copy of Forster's book, has made a note of its being referred by Banks and Solander to *Solidago*, under the name of *undulata*. Perhaps this is the most natural way of disposing of it; though if the calyx never contains but one floret, and is not in any way aggregate, the genus should stand in *Pentandria Monogynia*, along with *Corymbium*, at least according to the strict laws of artificial arrangement; but we should hardly, in either case, recommend such a measure.

SHAWLE, in *Agriculture*, a name applied to a shovel used in winnowing corn, in some places.

SHAWMGUNGE, in *Geography*, a town of Bengal; 18 miles W. of Rungpore. N. lat. 25° 27'. E. long. 88° 46'.

SHAWNAWAZ, a town of Hindoostan, in the subah

of Moultan; 70 miles N.E. of Moultan. N. lat.  $30^{\circ} 40'$ . E. long.  $77^{\circ} 38'$ .

**SHAWPOUR**, a town of Bengal; 42 miles S.E. of Moorshedabad.—Also, a town of Bengal; 30 miles S. of Calcutta. N. lat.  $22^{\circ} 5'$ . E. long.  $88^{\circ} 26'$ .—Also, a town of Hindoostan, in the circar of Surgooja; 28 miles N. of Surgooja. N. lat.  $23^{\circ} 35'$ . E. long.  $83^{\circ} 25'$ .—Also, a town of Hindoostan, in Berar; 45 miles N.W. of Maltoy.

**SHAWR**, a town of Syria, in the pachalic of Aleppo, situated in a romantic country, where the river Orontes winds majestically through the plain. The town is populous, and has a good caravanferai. Adjacent to it is a good stone bridge of seven arches. These conveniences have been originally provided for the caravan, which rests here in its route from Constantinople to Mecca.

**SHAWROWAH**, a town of Hindoostan, in the circar of Chanderee; 45 miles W. of Chanderee.

**SHAWSHEEN**, a considerable stream of America, in Massachusetts, which rises in Bedford county, Middlesex, and passing through Billerica, Tewksbury, and Andover, discharges itself into Merrimack river.

**SHAYE**, a town of Hindoostan, in Guzerat; 33 miles N.E. of Junagur.

**SHAYSHAR**, a town of Syria, anciently called *Larissa*, on the Orontes; 10 miles N. of Hamah.

**SHAZADABAD**, a town of Hindoostan, in Allahabad, on the right bank of the Ganges; 30 miles N.W. of Allahabad. N. lat.  $25^{\circ} 42'$ . E. long.  $81^{\circ} 43'$ .

**SHAZADPOUR**, a town of Hindoostan, in Bengal; 25 miles S.E. of Nattore. N. lat.  $24^{\circ} 12'$ . E. long.  $89^{\circ} 43'$ .

**SHEADING**, a riding, tything, or division, in the Isle of Man; the whole island being divided into six sheadings, in every one of which is a coroner, or chief constable, appointed by the delivery of a rod at the annual convention.

**SHEAF**, in *Agriculture*, a bundle of corn, as bound up in the field. Sheafs are made of very different sizes in different places, but they are best when not made too large. See **HARVEST**.

**SHEAF-Corn**, such grain as is in the state of ear in the straw before being threshed out. It is sometimes employed in this state as fodder for different sorts of live-stock.

**SHEAF of Arrows**, a bundle consisting of 24 in number.

**SHEAGUR**, in *Geography*, a town of Hindoostan, in Myfore; 4 miles W.N.W. of Vaniambaddy.

**SHEALLINGS**, in *Rural Economy*, the portions of rich grass-land in the more hilly and mountainous parts of the country, which were fixed upon, and taken possession of, by the farming inhabitants at an early period of society, for the purpose of retiring to, and grazing their cattle-stock upon, at certain seasons of the year. Some snug well-sheltered spot in such hilly ranges was always fixed on in this intention, which was removed from one to another whenever the cattle had consumed the grass of it; huts or cots being provided for the accompanying persons to live in, who had the care of the animals, &c.; a trusty servant being usually sent before hand to secure the spot, and drive away any wandering and trespassing cattle from it. This person was denominated the *poindler*, perhaps because he was authorized to poind or confine troublesome flock, and fix the fine established for the trespass. In some cases there were more than one such spots, and where they were very rich, as near lakes, brooks, or in vallies, the grass was consumed in common by two or more of them associating together. The sheallings were by no means, as

some have supposed, depastured at random, but according to the flock, or as they were *joined* out. See **SOUR**.

These shealling farmers lived with great simplicity, mostly on some oat-meal, and the produce of the dairy; having at the same time a constant occasional connection with their farms or home-steadings for the sake of performing different sorts of work on them, as collecting fuel, weeding flax, &c.: the last was mostly done by the women.

Though some of these sheallings still exist in the same way in the northern parts of Scotland, they are fast falling into disuse. In the room of such removals from place to place during the summer season, the distant grazings are frequently disjoined from the farmer's homestead, and left to shepherds, who live there all the year round, attending their flocks, in a modern house of substantial mason-work. In this mode of occupation, the landlord is said to draw more rent from his glens and mountainous property, and the farmers are at liberty, during the best season of the year, to ply the necessary and variety of labours wanted, for the improvement of their arable grounds, which, to industrious men, are never at an end.

The shealling season was, and is, as far as it yet continues, that of contentment, of festivity, of health, and of joy. The women are employed in spinning wool to clothe their families, and in making butter and cheese for part of their winter provisions. The youth are employed in fishing and wrestling, or athletic exercises, which put their swiftness and courage to the test, as a preparation for the more serious conflicts of a field of battle. When the various labours of the day are ended, the whole hamlet retires to rest, and to drown their fatigues in the soundest slumbers, on a bed of heath, the mellifluous fragrance of which perfumes the whole dwelling. See the *Agricultural Report* of the County of Inverness.

**SHEALLY**, in *Geography*, a town of Hindoostan, in the Carnatic; 10 miles S.W. of Tanjore.

**SHEAR**, in *Agriculture, a provincial word, signifying the reaping of grain. It is also applied to sheep, as one-shear or two-shear, which signifies one or two years old.*

**SHEAR-Off**, in the *Sea Language*. See **SHEERING**.

**SHEAR-Water**, in *Ornithology*, the *procellaria puffinus* of Linnæus, and called by some writers *avis diomedis*, is a bird about fifteen inches long, and thirty-one inches broad; the bill is an inch and three quarters long; the nostrils tubular; the head and whole upper side of the body, wings, tail, and thighs, are of a footy blackness; the under side, from chin to tail, and inner coverts of the wings, white; the legs weak, and compressed sideways; dusky behind, and whitish before.

These birds are found in the Calf of Man, whither they resort in February; taking possession of the rabbit-burrows, and then disappearing till April; the young, which are fit to be taken in the beginning of August, are killed in great numbers, salted, and barrelled; and when boiled, eaten with potatoes. They quit the isle the latter end of August, or beginning of September; and there is reason to imagine, that, like the storm-finch, they are dispersed over the whole Atlantic ocean. In the Orkney isles this species, called the *lyre*, is much valued for food, and for its feathers. They are taken and salted in August for winter provision. Pennant.

**SHEARDAY**, in *Agriculture*, provincially the sheep-shearing.

**SHEARING**, a term applied to the cutting of grain, and to a sheep that has been once shorn. See **SHEEP**.

**SHEARING, Sheep**. See **SHEEP-Shearing**.

**SHEARING**, in the *Woolen Manufacture*. See **SHEERING**.

**SHEARLING**, another term commonly applied to a sheep that has been once shorn by sheep-masters.

**SHEARPOUR**, in *Geography*, a town of Hindoostan, in Bengal, on the Burhampooter; 82 miles W.N.W. of Dacca. N. lat.  $24^{\circ} 53'$ . E. long.  $89^{\circ} 55'$ .

**SHEAT**, or **SHEET**, a name by which some call a young hog.

**SHEAT**, or *Sheats*, in a *Ship*. See **SHEET**.

If the main-sail sheats are haled aft, it is in order to make a ship keep by a wind, but when the fore-sheets are haled aft, it is that the ship may fall off from the wind; and if she will not do it readily, they then hale the fore-sail, by the sheat, flat in, as near the ship's sides as they can; and this they call *flattening the fore-sail*. When they say, *ease the sheat*, they mean veer it, or let it go out gently; but when the word is, *let fly the sheat*, they mean let it go all at once, and run out as fast as it can; and then the sail will hang loose, and hold no wind. The seamen say, when they would have the sheats of the main or fore-sail haled aft, *tally the sheats*. In a very great gale, or gust of wind, there is another rope bent to the clues of the main-sail and fore-sail, above the sheat-block, to succour and ease the sheat, and this they call a *false sheat*.

**SHEATS**, in a *Ship*, also, are those planks under water which come along her run, and are closed into the stern-post: so also that part within board, in the run of the ship, is called the *stern-sheats*.

**SHEAT**, *Falſe*. See **SHEET**.

**SHEAT**, *Overhale the*, in *Sea Language*, a word of command to hale upon the standing part of the sheat.

**SHEAT-Anchor**, in a *Ship*. See **ANCHOR**.

**SHEAT of a Plough**, in *Agriculture*, that part of the plough which passes through the beam, and is fastened to the share. It is sometimes called *sheath*.

And the sheat, or as it is sometimes called, the fore-sheat, there being another piece of timber behind it, which is called the hinder-sheat, should be seven inches wide, and fastened to the beam by a retch (a piece of iron with two legs), and by a wedge driven by it into the hole of the beam. But in the modern construction of this tool, the sheat is fastened without having recourse to these means. The angle contained between the sheat and the beam of the plough should be about forty-two degrees.

**SHEATH**, in *Botany*, is synonymous with *spatha*, *perichætiûm*, and *vagina*. In the first instance it belongs to the single-leaved covering, bursting longitudinally, which Linnæus reckons a kind of calyx, differing from a *perianthium* in being more or less remote from the flower. Such occurs in *Galanthus*, *Narcissus*, *Allium*, and others of the Hexandrous class; as also in *Arum*; and more especially in the natural order of **PALMÆ**. The **PERICHÆTIUM**, see that article, is the scaly sheath, or calyx, of Mosses. **VAGINA**, which will be further explained in its place, is the sheathing part of a leaf.

**SHEATHING of a Ship**, is the casing that part of her hull which is to be under water with something to keep the worms from eating into her planks.

It is usually done by laying tar and hair, mixed together, all over the old plank, and then nailing on thin new boards. But this hinders a ship's sailing; and therefore, of late, some have been sheathed with milled lead, which is much smoother, and consequently better for sailing; and also more cheap and durable than the other way. It was first invented by Sir Philip Howard, and major Watſon.

The sheathing with copper is a still later invention, and answers better than any other.

It is very well worth the trying what the new stone pitch will do in this case; if it will defend from the worm, as perhaps it may, a ship might be paid with it cheaper than with the crown pitch; and it will not crack nor scale off, as that will do, but keeps always soft and smooth. It has been found to continue on thirteen months, and to remain very black and soft all the time.

**SHEAVE**, a cylindrical wheel, made of hard wood or metal, moveable round a pin as its axis in a mortise, as being used to raise or increase the mechanical powers, as a pulley, applied to remove or lift weighty bodies. Sheaves are either fixed in blocks, to form tackles, or let through the ship's sides, for assisting to lead the tacks and sheets on board, or in mortises cut through the masts, yards, caps, &c. to facilitate the working of the rigging, and outer ends of the cat-heads, to form the cat-tackle to raise the anchor to the bow.

**SHEAVES**, in *Rural Economy*, provincially the broken parts of the stems of flax which come away in dressing. Also the small bundles of grain in the straw.

**SHEB**, in *Geography*, a town of Nubia, on the borders of Egypt, on the route from Charjé to Cobbé; 175 miles N. of Charjé. This place is occasionally infested by a tribe of the wandering Arabs, called *Ababdé*, who come from the neighbourhood of the Nile. Sheb is marked by the production of a great quantity of native alum, as the name imports. The surface, from which the alum is found, abounds with a reddish stone; and in many places is seen argillaceous earth.

**SHEBAT**, in *Chronology*, the eleventh month of the Jewish ecclesiastical year, answering to part of our January and February.

**SHEBBY**, or **SHELBY**, as Morſe has it, in *Geography*, a county of Kentucky, in the United States, containing 14,453 inhabitants, of whom 2996 are slaves.

**SHEBBYVILLE**, a town of the forementioned county, containing 424 inhabitants, of whom 118 are slaves; so that the total in the county and town includes 14,877 inhabitants.

**SHEBSHIR**, a town of Egypt; 9 miles S. of Amrus.

**SHEBUSTER**, a town of Persia, in the most picturesque, and, at the same time, the most flourishing division of Azerbaijan, which lies along the N. and W. borders of the lake of Urumea, from Tabreez to the confines of Armenia. Shebuster is a large and flourishing town.

**SHECATICA BAY**, a bay on the S. coast of Labrador. N. lat.  $51^{\circ} 20'$ . W. long.  $58^{\circ} 20'$ .

**SHECHALLION**, or **SHICHALLIN**, a lofty mountain in the parish of Fortingall, district of Rannoch, and county of Perth, Scotland, is situated in the immediate vicinity of Loch Rannoch. It rises in a conical form, and hence derives its name, which signifies the maiden's breast. According to mensuration, its height is 3564 feet above the level of its base, which nearly coincides with that of the ocean. This mountain is rocky and barren; but is particularly remarkable from the circumstance of its having been chosen by Dr. Maskelyne, late astronomer royal, for ascertaining the power of mountains in attracting the pendulum. Sinclair's Statistical Account of Scotland, vol. ii. 1792. See **ATTRACTION of Mountains**, and **MOUNTAINS**.

**SHECHINAH**, in the *Jewish History*, the name of that miraculous light, or visible glory, which was a symbol of the special presence of the Deity. This shechinah, after it had conducted the Israelites through the wilderness, had its more stated residence in the tabernacle and the temple. See **ARK of the Covenant**.

For a farther account of this miraculous phenomenon, the

the reader may consult part ii. chap. 2. of Mr. Lowman's *Rationale of the Hebrew Ritual*.

Toland, in his *Tetradymus*, has attempted to prove, that this appearance had nothing miraculous in it, but was only a kind of beacon, used by the Israelites for their direction in their journey.

**SHED BUILDING**, in *Agriculture*, a term applied to any sort of slight temporary building.

**SHED**, *Open*, a sort of slight open building, for containing cattle, and various other uses in the farm-yard. See **CATTLE Shed**.

**SHED**, in *Rural Economy*, a term signifying to part, with the fingers and thumb, wool, hair, &c. as in salving sheep.

**SHEDDING of the Hair**, in horses, is the casting of the coat. See **MOULTING**.

**SHEDIAC**, in *Geography*, a harbour on the E. coast of New Brunswick.

**SHEDMA**, a province of Morocco, containing 550,000 inhabitants. This province produces wheat and barley; its fruits are not so rich as those of the north, or of Sufe; it abounds however in cattle. Of goats it furnishes annually an incalculable number, the skins of which form a principal article of exportation from the port of Mogodor; and such are often the animosity and opposition among the merchants there, that they have sometimes given as much for the skin, as the animal itself was sold for. Honey, wax, and tobacco are produced in this province; the two former in great abundance; also gum arabic, called by the Arabs "Alk tolh," but of an inferior quality to that of the Morocco district.

**SHEDUAN**, an island in the Red sea, about nine miles long and six broad. It is high and craggy, without wood or water; it is situated at about an equal distance between the two coasts of Egypt and Arabia. N. lat. 27° 34'.

**SHEEDWOOD**, in *Rural Economy*, provincially rough poles of top wood. See **WOOD**.

**SHEEHY MOUNTAINS**, in *Geography*, the name of a range of mountains in the barony of Muskerry, and western part of the county of Cork, in Ireland. Of these and other mountains along the confines of Kerry, it is observed by Mr. Townsend, in his *Statistical Survey*, that though sometimes high, they generally want grandeur, and that the intermediate hollows are seldom marked with striking or romantic scenery. The adjoining lands are rude, rugged, and stony in the extreme, with a very scanty intermixture of any thing fair or fertile to relieve the eye amidst such a dreary waste.

**SHEELAMoola**, a town of Hindoostan, in Coimbatore; 14 miles S. of Erroad.

**SHEELIN**, or, as Arrowsmith spells it, *Shillin*, a lake on the south of the county of Cavan, Ireland, situated between it and the counties of Meath and Westmeath. The river Inny flows from this lake, of which Mr. Edgeworth has said, in his report to the Bog commissioners, that it is in many places a fine deep river, and capable of being rendered navigable at a small expence, and to great national advantage.

**SHEEP**, in *Zoology*. See **OVIS**.

**SHEEP**, in *Agriculture and Rural Economy*, a well-known species or kind of live-stock kept by the farmer. The sheep belongs to the class of ruminant animals, or such as chew the cud, and of which there are different species, and varieties or breeds. And in its generic character it is distinguished by being with or without horns, which are hollow, wrinkled, turning backward, or intorted in a spiral manner. Eight front teeth in the lower jaw, in the upper none.

It is evident that sheep are animals of the utmost importance to mankind, whether considered in the light of affording food and clothing, or in that of the vast improvement and profit which they produce in the various systems of management to which they are subjected by the farmer; in some instances constituting a very large proportion, and in others nearly the whole of his dependence and support. There is also another point of view in which they appear equally advantageous and interesting, which is that of their becoming thus beneficial in situations and upon lands that must otherwise be nearly if not wholly useless. Also in the view of affording the raw material for one of the most extensive staple manufactures of the kingdom, the advantages which they afford are almost incalculable.

But besides the wool, the skins and other parts of these animals afford a variety of other equally useful and important articles and products, such as those of parchment, leather, glue, suet, and many others, which are of great value for different intentions and purposes in the arts and other ways, and which employ a great number of labourers in forming and preparing them. In short, there is hardly a part of the sheep that does not afford an useful and valuable product of some sort or other. In usefulness they may, of course, be placed at least next to, if not before, the cow. In disposition, almost all the improved breeds are extremely mild, tame, and gentle, which is a proof of their value as grazing stock: but those which have been less attended to, or which continue more in their native or original state, are much less tractable, as those which inhabit the downs, heaths, and mountains in different parts of the island.

The character of stupidity, want of sagacity, and of some other valuable properties, which the naturalist Buffon has given these animals, seems by no means well-founded. It is probably the offspring of prejudice, and the improper examination of the subject.

The increase or growth of the sheep continues to advance till at least three years old, when it is in general considered as in the most proper state for the purposes of the grazier, though it is employed in this way till a much later period, sometimes even till five or six, and also with the view of breeding; but an early maturity is a property of much consequence, especially for the grazier. Of sheep, the breeds or varieties that are dispersed over the globe are almost endless; even in this country they are so extremely numerous as scarcely to be described with any correctness. The characteristic circumstances by which they have been chiefly distinguished, are those of their possessing horns, or being wholly without them, and from the length or shortness and fineness of the wool or coat, as well as the situation in which they are chiefly found. It has been stated by lord Somerville, in his "System of the Board of Agriculture," that all the breeds of sheep in this kingdom may be arranged into two classes; those which shear the short or clothing, and those which shear the long or combing wool. And that the quality of the flesh in each class follows the character of the wool; the short-wooled sheep being close in the grain as to flesh, consequently heavy in the scale, and high-flavoured as to the taste; the polled long-wooled sheep more open and loose in the grain, and larger in size. And by the author of "The present State of Husbandry in Great Britain," they have been distributed under three general divisions, as below:

1. The mountain breed;
2. The short-wooled breed; and
3. The long-wooled breed.

And among the first are comprised several varieties, as the black-faced, which range on the mountains of Wales, Westmore-

# SHEEP.

Westmoreland, Cumberland, Yorkshire, and those in the south, west, and north of Scotland, and in the Shetland islands; the Cheviot hills, in the south of Scotland and north of England; and the forest and common sheep of the last-mentioned country. In the second division are included those of Hereford, Dorset, Suffolk, Norfolk, and some parts of Cumberland. And the third division comprehends all those varieties that are dispersed over the more rich and fertile parts of England, and which are distin-

guished under the titles of the Durham or Teefwaters, the Lincolnshires, the old and new Leicestershires, &c.

But others divide them into *long*, *short*, and *middle-woolled* kinds.

And a still more clear and concise view of the various breeds of British sheep, is afforded in the tabular form given by Mr. Culley, as enlarged and corrected by the author of the "General Treatise on Cattle," and others.

TABLE of the Breeds or Varieties of Sheep in England.

Names of Breeds.				Weight of Fleece.	Wethers per Quar.	Age killed.
1. Teefwater.	No horns.	White face and legs.	Long wool.	9lb.	30lb.	2 years
2. Lincoln.	No horns.	White face and legs.	Long wool.	11	25	2
3. New Leicester.	No horns.	White face and legs.	Long wool (fine).	8	22	2
4. Cotswold.	No horns.	White face and legs.	Long wool (fine).	9	24	2
5. Romney-Marsh.	No horns.	White face and legs.	Long wool (fine).	8	22	2
6. Dartmoor or Bampton.	No horns.	White face and legs.	Long wool (fine).	9	25	2
7. Exmoor.	Horned.	White face and legs.	Long wool (coarse).	6	16	2½
8. Heath.	Horned.	Black face and legs.	Long wool (coarse).	3	15	3½
9. Hereford, Ryeland.	No horns.	White face and legs.	Short wool (fine).	2½	14	3½
10. Morf, Shropshire.	Horned.	Black and speckled.	Short wool (fine).	1½	12	3½
11. Dorset.	Horned.	White and speckled.	Short wool (fine).	3½	18	2
12. Wilts.	Horned.	White and speckled.	Short (mid.)	3	20	3
13. Berks.	No horns.	Black and white.	Long wool.	7	18	2½
14. South Down.	No horns.	Speckled and white.	Short wool.	2½	18	2
15. Norfolk.	Horned.	Black and white.	Short wool.	2	18	3½
16. Herdwick.	Horned.	Speckled and white.	Short wool.	2	10	4½
17. Cheviot.	No horns.	White face and legs.	Short wool.	3	16	4½
18. Dun-faced.	No horns.	Dun face and legs.	Short wool.	1½	7	4½
19. Shetland.	No horns.	Various coloured ditto.	Fine cottony.	1¼	8	4½
20. Spanish.	Rams-horned.	White.	Short wool (super.)	3½	14	2½
21. Ditto crosses.			Ditto fine.	2½	16	2

There are a few other breeds met with in different districts, as noticed below.

Since it is found by the grazier that the more an animal approaches towards perfection in its form, the better, in general, it is adapted to the purpose of fattening; it is obviously a matter of much importance to be well acquainted with the peculiar disposition and connection of parts which constitute such excellence or perfection of form: these have been already fully explained in speaking of the nature and principles of breeding animals, as well as in considering the nature and management of cattle. And the same thing is to be aimed at in sheep-stock; as the more any breed may approximate to such an excellence of shape, the more perfect it must be. A sort of model to be aimed at, in so far as shape is concerned, in the improvement of these animals, due attention being always had to other properties, has been given by Mr. Culley, in his description of a ram, and which may be seen under that head. (See RAM.) The nature and combination of the various points and parts should, of course, be well understood and impressed on the mind of the breeding and grazing farmer, in order that he may always rear or procure these animals to the greatest advantage.

The varieties of this most useful animal are endowed with different particular qualities, properties, powers, and propensities, which it is necessary to ascertain, in order for the farmer to draw and produce the utmost advantage possible from the combining, crossing, and rearing of them. All

the breeds of sheep are the most distinct while they are kept or left in the state of nature.

The common and usual descriptions of the several breeds are the following:

*Teefwater Breed or Variety.*—This is a breed of sheep said to be the largest in the island; it is at present the most prevalent in the rich, fine, fertile, inclosed lands on the banks of the Tees in Yorkshire. In this breed, which is supposed to be from the same stock as those of the Lincolns, greater attention seems to have been paid to size than wool. It is, however, a breed only calculated for warm rich pastures, where they are kept in small lots, in small inclosures, and well supported with food in severe winter seasons. The produce in weight of mutton is large, but then, from their requiring so much longer time and richer keep, and being admitted in so much smaller proportions on the acre, they are probably not, upon the whole, so profitable, even in situations where they can be kept with the greatest chance of success, as the smaller more quick-feeding breeds. In the ewes there is, however, a property which is of much consequence, which is, that in general they are very prolific, bringing two and frequently three lambs, and in some cases a greater number each, according to Mr. Culley. He gives the following description of the breed. The legs are longer, finer boned, and support a thicker and more firm and heavy carcase than the Lincolnshires; the sheep are much wider on the backs and sides, and afford a fatter and finer grained mutton. The weight per quarter in two-years old

## SHEEP.

old wethers is from 25lbs. to 35lbs., and in particular instances to 55lbs. or more. The wool is shorter and less heavy than in that breed. However, the writer of the "Treatise on Cattle," thinks that the breed is nearly worn out; but suggests that there is a similar breed in Ireland.

This is a sort of sheep that has been little attended to, but which, when improved by proper crossing, it is supposed, would answer and pay well in districts where it could be well supported. In the Corrected Report of the State of Agriculture in the West Riding of Yorkshire, Mr. Parkinson supposes that an useful kind is capable of being bred by crossing the ewes of this sort with Dishley rams, in a careful manner. And it is added, that by the use of these, and those of the Northumberland kind, the quality of the wool and the mutton has not only been greatly improved, but the quantity of bone and offal much lessened; and, at the same time, the fattening property considerably increased; they becoming fatter at two years old than the others are at three. The wethers of this improved sort generally sell unshorn, at two years old, from 45s. to 55s. a-piece, and weigh from twenty-four to thirty pounds the quarter. They sell a great deal higher at the present time.

*Lincolnshire Breed or Variety.*—This is a breed of sheep which is characterized by their having no horns; white faces; long, thin, weak carcasses; thick, rough, white legs; bones large; pelts thick; slow-feeding; mutton coarse-grained; the weight per quarter in ewes from 14lbs. to 20lbs.; in three-year old wethers from 20lbs. to 30lbs.; the wool from 10 to 18 inches in length. And it is chiefly prevalent in the district which gives the name, and other rich grazing ones. But the writer of the work on Live-stock supposes that this breed is now so generally improved by new Leicester tups, that they are probably, in a great measure, free from those defects of the old breed, of which Mr. Culley, with much reason, complained, namely, slow feeding, from a looseness of form, and too much bone, and coarse-grained flesh. It must not, however, be denied, that a good old Lincoln has ever been, and the name, at least, still continues a great favourite at Smithfield, and the flavour of the Lincoln mutton has been generally held superior, as more savory than the Dishley. The new or improved Lineolns have now finer bone, with broader loins and trussed carcasses, and are among the best, if not actually the best, long-woolled stock we have. Many will recollect the ridiculous and indecorous squabble, some years ago, between two eminent breeders concerning these two breeds of sheep. About this time, they attempted to feed Lincoln sheep on the Essex marshes, and pretended the stock degenerated, which might happen from insufficiency of winter keep, or, if they were breeding ilks, from crossing with other breeds, an everlasting and unregarded practice in those not professedly breeding counties. This has been suggested as a breed only capable of being made fat on the richest grazing lands; but that in such cases it may probably be kept till three years old, with greater profit than the new Leicester kind. The proportion of bone to mutton is considerable, and the latter not very fine in quality. But the principal excellence of the breed is in the large quantity which it affords, which pays for their being kept longer before they are fatted. Such breeds as feed quicker should however be preferred by the farmer on moist sorts of land.

*New Leicester, or Dishley Breed or Variety.*—This is an improved breed of sheep, which is readily distinguished from the other long-woolled sorts, according to Culley, by having fine lively eyes; clean heads, without horns; straight, broad, flat backs; round or barrel-shaped bodies; fine small bones; thin pelts; and a disposition to make fat at an early age; to which may be added a superiority in the

fineness of the grain and the flavour of the mutton to that of other sheep of the large long-woolled kinds. The weight per quarter in ewes three or four years old from 18lbs. to 26lbs.; in two-year old wethers, from 20lbs. to 30lbs.; the length of wool from six to fourteen inches. But the author of the "Treatise on Live-Stock," characterizes them as having a fulness of form and substantial width of carcass, with a peculiar plumpness and meekness of countenance; the head long, thin, and leaning backward; the nose projecting forward; the ears somewhat long, and standing backward; great fulness of the fore-quarters; legs of moderate length, and the finest bone; tail small; fleece well covering the body, of the shortest and finest of the combing wools, the length of staple six or seven inches. The fore-flank, a term of the old school, current in the time of Lisle, or that flap of skin and fat appended to the ribs, and the inferior part of the shoulder, is remarkably capacious in this breed. New Leicester mutton, it is believed, is the most finely grained of all the large long-woolled species, but of a flavour bordering on the insipid. And it is added, that it is reported, and with the strongest probability, from the appearance of the flock, the fineness of the wool, and the grain of the mutton, that a Ryeland cross was a prime instrument in the Dishley improvement of sheep. Probably the root or foundation was Lincoln. In the ordinary and gradual course of improvement or alteration of form, it must have taken, it is thought, a long time and vast pains, to mould the animals into that artificial and peculiar shape which distinguishes this remarkable variety, unless indeed something nearly similar was suddenly and fortuitously chopped upon, as will occasionally happen when the sickle duty is good-humouredly disposed to spare our labours.

It must be observed, that the great advantages of this sort of sheep have been stated to consist in producing a better profit to the farmer, in proportion to the quantity of food consumed, than most others; in being more perfectly formed, and consequently more disposed to fatten quickly; in containing a much larger proportion of meat on an equal weight of bone; in thriving well on such pastures as would not support other sorts of the same size; in being capable of being kept or fattened in larger proportions to the acre, than other breeds of the same size of carcass; in the wool being more valuable, though less in quantity; in their being ready for the butcher in the early part of the spring instead of the autumn, by which there is a considerable saving in the farmer's grats; and in the mutton, from the closeness of its texture, keeping longer than that of other equal-sized breeds. And that the principal defects are the fattening too much, and the mutton, in consequence, becoming less delicate in its flavour, than in that of other breeds that require a greater length of time in the process; the deficiency in the quantity of wool which they produce; and the not being calculated for the fold. It has also been supposed that their peculiar rounded form, from throwing much of the fat on the external parts, prevents their fattening well internally; and that from their great propensity to fatten, they are liable to early decay, becoming old sooner than other breeds. There can however be no doubt, but that it is a valuable breed on pastures that are adapted to it, as is evinced from its rapidly making its way into different districts of the kingdom; but some suppose that the sheep are too small, and that, from the thinness of their skins, or pelts, they may not be so capable of bearing cold, which, however, experience does not appear to support.

The author of the "Treatise on Cattle," who seems chiefly to object to the Leicester breed, from its too great propensity to fatten, which, it is supposed, also abates the

procure-

# SHEEP.

procreative and lactiferous powers, says, "Pure Dishley sheep are by no means the most prolific, nor the best nurses." And adds, that the heads of the improvers having had time to cool, it is no longer boasted, that new Leicester sheep are able to subsist, and even thrive, on the shortest commons. In fine, it is contended, the merits of this stock as an improving cross, (their grand point of utility,) being so undeniably great, their disadvantages have been overlooked, and comparisons have been usually made with such only as had a strong need of improvement, in which the new Leicesters in course were sure to triumph. And further, that though the Dishley cross has made its way into every part of this island, to the Land's End, to the bottoms of the Welsh mountains, and of the Scottish Highlands, to Ireland, and even to Russia, its general success has been attended with various particular instances of failure, a remarkable one of which is given by Lord Somerville, in his Facts, in respect to the Bampton or Western long-wooled sheep. The cross is sometimes very injudiciously used with short or carding wool flock, excepting where the intention is only forward lamb. On stock naturally good and improveable, this peculiar effect of the new Leicester cross has resulted, the improved have considerably surpassed, in the most valuable properties, their improvers. Of this many examples may be seen, it is supposed, in the improved Lincoln, Northumberland, and Midland county sheep.

The following is a table of the value of new Leicester sheep, at various ages, as given on the authority of different eminent breeders in the Lincolnshire Agricultural Survey.

Wether lambs, at 6 months, worth	17s.
—————, at 12 months	30s.
—————, at 18 months	35s.
—————, at 24 months	45s.
—————, at 30 months	45s.
—————, at 36 months	55s.

But others, in different parts of the district, state it thus :

Leicesters, at six months old, worth	14s.
—————, at twelve ditto	22s.
—————, at eighteen ditto	28s.
—————, at twenty-four ditto	35s.
—————, at thirty ditto	45s.
—————, and, if kept to thirty-six, would be	50s.

If a three-shear fells for 3*l.* it will be worth,

At 6 months, 28s.	
At 12 months, 35s.	Wool 9½ <i>lbs.</i>
At 18 months, 40s.	
At 24 months, 48s.	Wool 9 <i>lbs.</i>
At 30 months, 56s.	
At 36 months, 60s.	Wool 9 <i>lbs.</i>

According to the first of these tables, the scale of receipt is ;

	£	s.	d.
For the first summer	0	17	0
For the first winter	0	13	0
For the second summer, including 8 <i>lbs.</i> wool at 9 <i>d.</i>	0	11	0
For the second winter	0	10	0
For the third summer, including wool	0	6	0
For the third winter, including wool	0	16	0
Three fleeces	3	13	0
	0	18	0
As above	2	15	0

At 73*s.* they pay, *per annum*, 24*s.* 4*d.*

And it is remarked, that, at these prices, the last half year pays better than any ; if this is just, there is a great loss, by felling at 2½ years old ; for it is just at the conclusion of the worst half year there is.

Mr. Dawson of Berthorp, who has an excellent stock bred from Mr. Dalby's tups, last year sold 200 two-shear wethers at 3*l.* round. The following is his table of sales for seven years, of wethers of that age.

1790 Average	35 <i>s.</i>
1791	35 <i>s.</i>
1792	43 <i>s.</i>
1793	38 <i>s.</i>
1794	44 <i>s.</i>
1795	50 <i>s.</i>
1796	60 <i>s.</i>

He tuds three*s.* Average 2*l.* 3*s.* 6*d.*

And, at this average, he would thus divide it, by supposing the proportion to be,

	£	s.	d.
At 6 months	0	17	0
At 12 months	1	7	0
At 18 months	1	12	0
At 24 months	2	0	0
At 30 months	2	3	6

The advantages and disadvantages of the Lincoln and new Leicester breeds of sheep have been very fully considered in the Agricultural Survey of the former county ; and the results stated as below in the different districts of it.

Circumstances of comparison between the Lincoln and Leicester breeds of sheep.

- Boston. Lincoln better than Leicester, on general experience and particular experiment.
- Brothertoft. In experiment, very little difference.
- Ewerby. Leicester tenderer than Lincoln. Lincoln pay best for keeping to three-shear.
- Hackington. Last year of Lincolns pay best.
- Ewerby. Old sheep stand the winter better, and pay better than young.
- Owerby. Shearling Leicesters have, at Wakefield, sold as high as two-shear Lincolns. Difference of wool has been as 8 to 16. Leicesters tenderer in winter.
- Normanby. Lincoln fleece 2*lbs.* heavier than Leicester. Leicester off-shearlings ; Lincolns two or three-shear, but the latter pay well, if kept to three-shear. Leicesters finer grained mutton. Leicesters rather thicker on the land, but Lincolns considerably larger. As much wool *per acre* from Leicesters as Lincolns.
- Walcot. Leicester fleeces, though not so heavy as Lincoln, sold, in one instance, for as much money.
- Barton. Leicester not tenderer in winter than Lincoln. Old breed of Lincoln used to go lean at two years old. Now, Leicesters fat at the same age. No difference in number on the same land. Wool the same.
- Bonby. Leicesters come to sale sooner, but will not bear cold, wet land in winter so well, nor heat or cold after shearing, as the Lincoln.
- Barrow. Five Leicesters where four Lincolns ; and Leicesters have resisted hardships on the worst land better.

Brocklesby.

## SHEEP.

- Brocklesby.** Lincoln more profitable than Leicester.
- Lumber.** Where a man can keep, by means of marsh, to three-shear, Lincoln most profitable, but not otherwise. Not more Leicesters kept on the same land. Leicester wool is a tod more than Lincoln. Leicester more liable to the fly.
- Cadney.** Leicester will feed a little faster, and run a little thicker.
- Belesby.** Leicester one in six more on the same land, but both go at the same age. Leicesters hardier, and have less offal. Tallow equal; wool higher priced. Gives corn to Leicesters, but did not to Lincolns.
- Alesby.** Leicesters feed quicker, and have less offal; wethers and hogs less wool, but ewes equal, and on the whole more *per acre*; hardier, and bear driving better. Go off at the same age, but Leicesters fatter. Five kept instead of four. Lamb easier; necessary to give corn.
- Humberston.** More pride than profit in the new sort. Leicesters 2lbs. less wool than Lincolns, and not better; but run one in ten thicker.
- Louth.** Leicesters feed quicker, and have lighter offals. No difference in hardiness. Lincoln best.
- Tathwell.** Lincolns and Leicesters being put together into the marsh, and sent thence at same time to Smithfield; the former yielded 4s. a-head more, and 5s. a-head more wool.
- Cookswold.** Marsh graziers all prefer Lincoln. No difference in number kept.
- Tathwell.** Lincoln wool 4lbs. heavier than Leicester. At two-shear, Lincoln heavier by 2lbs. a quarter; at three-shear, 5lbs. In tallow, 6lbs. at three-shear, in favour of Lincoln. In number *per acre* no difference. In hardiness, Lincoln best. Leicesters less wool, and less mutton *per acre*.
- Driby.** No difference in number kept.
- Spillsby.** Leicesters as fat at Lady-day, coming two-shear, as Lincolns at Lammas. Same number *per acre*. No difference in hardiness; Leicesters have corn.
- Horncastle.** Three-shear better than two, as sure to find more tallow.
- Asgarby.** Leicesters bred too fine; fine-headed ones do not yield wool enough.
- Frampton.** As many of one as the other *per acre*. Lincolns travel best, and pay best.
- Ranby.** Leicesters thicker on land, as five to four.
- Alderkirk.** In an experiment of the two breeds on the same land, of the same weight and age, the Lincolns considerably superior.
- Thoresway.** True Lincolns most saleable, and most profitable to breed.
- Sudbrook.** One-third more Leicesters on the same land.
- Rifeholm.** Boston graziers not judges, for they can get good Lincolns, but not Leicesters, as the breeders of these can fat them themselves. Leicesters ran one-fourth thicker on the land. From six to twelve months old, rather tenderer than Lincolns; Leicesters travel best.
- Claypool.** Leicesters as fat at one year as Lincolns at two, and with less trouble, and one-tenth thicker. Do as well as Lincolns in winter on wet land.
- Marston.** Leicesters best, and run one-sixth thicker.
- Woolthorpe.** Leicesters by far the best; but more apt to be barren than Lincoln. Drape ewes far more valuable.
- Grimthorpe.** Leicesters travel best, and are the best; and much less loss in lambing; run one-third thicker.

A clear distinction is to be drawn, as the writer remarks, between the rich south-eastern district and inferior soils; for, upon the former, the information is strong in favour of Lincoln. However, in general, he should observe, that the new Leicesters are spreading very rapidly over the country, probably faster than they have done in any other, one or two only excepted, which may be attributed to the general goodness of the soil; for this breed makes a much more respectable figure here than it has done in various trials made in counties inferior to it in soil; and the breed driving out the Lincolns so much as it has done in the poorer parts of this county, is a fact that unites with this circumstance. The true Lincoln is a large sheep, and with a longer wool, and therefore demands better pasturage; where it finds such, there the old breed remains; subject, perhaps, to little more change than fashion may cause. Upon inferior land the Leicester establishes itself; and upon land still inferior in other counties, experiments prove unsuccessful for the same reason; that of the necessity of having a smaller size and shorter wool.

But some of the original pure long-woolled polled breed of sheep, are still to be met with in the midland districts, which are a larger boned, longer formed, deeper coated, and more coarse stock than the improved sort. And that, from the coarseness and larger size of the head and neck in the old sort, the ewes lamb with more difficulty than in the true Dishley breed.

The new Leicester sort of sheep is found a very advantageous breed on some kinds of land in the county of Oxford, as on the stone-brash; there are some farmers indeed, who think that no other sort comes nearly up to them, when all their valuable properties are taken into the account.

*Cotswold or Gloucester Breed or Variety.*—This is a breed of sheep which, according to a late writer on them, is of the fine combing wool sort, deriving the fineness of their fleece from the same source as the new Leicesters. This part of that county formerly, and within memory, bred, it is said, small fine-woolled sheep of the Ryeland kind, which in past times had been cotted, but the practice was discontinued. These sheep, being judged too small for the improving state of the county, have been, by gradual crossings with Midland long-woolled rams, chiefly Warwicks, completely changed from short to large long-woolled stock. The writer saw a picked lot of Cotswolds last year, he says, which answered the following description: long coarse head, with a particular blunt, wide nose; a top-knot of wool on the forehead, running under the ears; rather long neck; great length and breadth of back and loin; full thigh, with more substance in the hinder than fore-quarters; bone somewhat fine; legs not long; fleece soft, like that of the Dishley, but in closeness and darkness of colour, bearing more resemblance to short or carding wool. Although very fat, they had all the appearance of sheep that were full of solid flesh, which would come heavy to the scale. It is added, that it is said, some of those sheep have reached 40, and even 50lbs. a quarter,

## SHEEP.

a quarter, at two years and a half old, giving 11lbs. to 14lbs. of wool each sheep, and being fat, they are indubitably among the largest breeds in England. A single dip, continues he, of new Leicester gives the Cotswolds a fulness in the fore-quarter; but any farther crosses of that kind, it appears, diminishes their size. The strange crosses of Wilts horned sheep has been resorted to in some parts, for no possible good purpose, he should apprehend, either to the carcass or wool; and it is probable, supposing such large stock profitable, that the chief alteration required by the Cotswolds, is to encourage length of staple in their fleece or wool.

In this breed the ewes are usually put to the tup, so as to have lambs at two years old, mostly producing two lambs each, in the proportion of nearly one-third of the whole, where kept well, which must always be done. They may be kept for breeding till three or four years old, if they are of the proper improved sort. But it is said that the wethers afford most profit when killed so early as at two years old, as they are apt to become too fat when kept longer.

The Cotswolds or Gloucesters, and the half Leicesters and half Gloucesters, and other mixtures of these breeds, are considered as very excellent sorts of sheep stock in many parts of Oxfordshire; they are of a good size, bear plenty of wool, and stand penning well. But penning or folding is not thought beneficial by some farmers, as more and better sheep may be kept without it.

The native Cotswolds, if they are any where to be found, would be, it is said, at two-shear from twenty-eight to thirty-two pounds the quarter: they are a long sort of sheep, not full in the sides, sharp in the chine, not full in the fore-flank, coarse in the bone, not straight but good in the hind-quarters; will not fatten so early as when crossed; and of wool, the two-shear wether affords three and a half fleeces to the tod. The new Leicester, it is contended, is calculated to correct every one of the deficiencies which have been noticed, and to bring a greater disposition to fatten. Between all Cotswold and all Leicester, the average difference of wool, it is said, is three pounds.

In Devonshire, some, it is said, have succeeded in the cross of new Leicester upon the Cotswold, the equal breed of which is attempted to be preserved as much as possible. Wethers of this kind, at eighteen months old, will average nineteen pounds the quarter, and seven pounds of unwashed wool the fleece. When kept on for another twelvemonth, the age at which they are mostly killed in this county, this cross will attain the size of twenty-five pounds the quarter, and yield nine pounds of wool to the fleece. This wool is allowed by the staplers to be one penny the pound superior to that of the Exmoor, Bampton, South Devon, and Dartmoor sheep, yet still the common price of 10d. the pound is only allowed for it. In the young wethers of this breed, the loose fat is stated to be nine pounds, with nearly three pounds of kidney fat on each side. The larger wethers are said to produce thirteen pounds of rough fat, and four pounds of kidney fat on the side.

*Romney-Marsh Breed or Variety.*—This is a kind which is described by Mr. Young, as being a breed of sheep without horns; white faces and legs; rather long in the legs; good size; body rather long, but well barrel-shaped; bones rather large; and it is said that the weight *per* quarter, in fat wethers at two years old, is usually from 22lbs. to 28lbs. In respect to the wool, it is fine, long, and of a delicate white colour, when in its perfect state. On this Marsh 20lbs. of wool are supposed to be produced *per* acre. In this breed there is a property of arriving at the state of fatness at an early age, as well as that of producing a large fleece of fine

long combing wool, of course it is a valuable sort; however, from the size, and great weight of the coat, it is only capable of being supported and fattened on the rich kinds of marsh pasture: and on those which extend from Hastings to Rye, in Kent, according to the Suffex Agricultural Report, the graziers find it much more beneficial than the South Down; the marsh wethers fattening more quickly. The wool afforded by such fat wethers averaging six pounds, and in breeding ewes five pounds, but not equal in quality to the wool clipped from shearlings. And the author of the "Synopsis of Husbandry" remarks, that a convincing proof of the great value of this breed of sheep, as well as of the land on which they are fed, is seen in the manner of stocking, which in tegs is from four to seven *per* acre, in fattening wethers from six to eight, in barrens from two to three, and in couples three; which is certainly a great flock. And this is a breed that might probably undergo much improvement without crossing, by proper care and attention, and being less exposed in the winter season.

In the old Romney-Marsh breed, the sheep were remarkable for having large heads; for being large, long, and tubbellied; also for being large in their bone, long in their legs, and coarse in their wool; which form is still held in estimation by some, in consequence of improper prejudices, to the great injury of the grazier and community in general; but the pure breed of this sort, Mr. Price says, is distinguished by a thickness and length of head, a broad forehead, with a tuft of wool upon it, a long thick neck, a great length and thickness of carcass; being flat-sided, and having a sharp chine, tolerably wide on the loin, but the breast narrow, not deep, the fore-quarter not heavy or full, a good cleft; the thigh full and broad, the belly large and tubby; the tail thick, long, and coarse, the legs thick with large feet, the muscle coarse and the bone large: the wool long and not fine; coarsest on the breech: the sheep prove good, and are great favourites with the butchers. But this description is not now, it is said, so applicable as it was some time ago, when most of them had horns.

The same writer, in his account of the sheep management in this marsh district, has remarked, that the introduction of the Leicester breed has very perceptibly altered the form and properties of the original breed or stock of this tract, so that in a few years it will scarcely be discernible. And that it is probably the general opinion that it has been injurious to it, in reducing the size and value of the animal, as well as the quality and quantity of its wool, though it has still many advocates, and has certainly contributed much to its improvement. The principal objections which the graziers of this Marsh seem to have to the mixing of the Leicesters with their own breed, are, that they have seldom or ever twin lambs, which are very desirable and beneficial in this situation; that the lambs are more tender, and, of course, a greater loss liable to be sustained, especially in an open exposed tract of this sort; that their lambs do not winter so well as those of the native breed upon the uplands: they are much less hardy, consequently cannot stand cold and hardships so well, which is very disadvantageous; that their wool is not in such abundance, or so valuable, which is a great defect; that there is a want of proof in them, which renders them a great deal less saleable to the butcher; this may, however, be no disadvantage to the breeder or grazier, as it shews other more valuable properties and dispositions; and that they are too short in their bodies and legs, so as to stand too low in their pens at the market. These are, however, probably improved valuable properties, which must be rather beneficial than hurtful. Some improvement has, however, been given to the Marsh breed by the Leicester cross, as those

## SHEEP.

those of smaller and less coarse heads, a greater depth of carcass, and shorter and less coarse legs, better symmetry or form of several different parts, as well as of the whole animal.

There can, therefore, be no doubt but that this breed has been greatly benefited by the introduction of the new Leicester sort, and it is probable that it has not depended so much upon selection as the use of this new variety, as though the cry in the market is for the marsh kind, that form is carefully improved, and by no means preserved, although something of it may still exist. Something of the South Down sort is likewise discernible in this breed, it is said.

This breed of sheep is thought to be highly valuable for cold exposed situations, as being easily bred, and standing in need of no artificial food in the most severe winters, except a little hay; they are very hardy for their size, have now many improved qualities, and may probably be made the most profitable of any for rich pastures, as affording the largest proportion of meat at the least expence. In wethers, the general average is now from ten to twelve stone weight each; and in ewes, when fat, from nine to eleven.

*Dartmoor, Devonshire, Bampton and Nott Breed or Variety.*—This is a breed or sort of sheep, which is chiefly distinguished by having no horns; white faces and legs, thick necks, backs narrow, and back-bones high; sides good; legs short, and bones large; and probably without any material objection, being a variety of the common hornless sort. According to Mr. Culley, the weight of ewes on the average about 20lbs. a quarter: in wethers, at two years and a half old, 30lbs. Length of wool much the same as in the Romney-Marsh breed. It is a breed found to be prevalent in the districts from which it has derived its name. And it is supposed to have received considerable improvement by being crossed with the new Leicester or Dishley improved sort within these few late years.

Besides the forest from which it takes its name, this breed is met with in some other parts of the county. The Dartmoor wethers at five years old will average about 16lbs. per quarter, and produce from four pounds and a half to six pounds and a half of unwashed wool to the fleece. This breed of sheep, though they do not feed so quickly, when put to good keep, as the new Leicester sort, yet, when fat, they constantly prove the very best mutton, and never fail to command a superior price. They also stand the climate in a favourable manner, and the ewes are good nurses.

The old Devonshire dun-faced nott sheep were formerly held in high estimation, as a native breed of some parts of this county. It is, however, a crooked-backed, flat-sided,

coarsely boned and woolled animal, but which has been much improved by crossing with the new Leicester sort; its principal defects are by these means removed, and a greater disposition to fatten at an earlier period given; while at the same time, however, the fleece, as well as the weight of the carcass, has been lessened, the former from ten to eight pounds of unwashed wool the fleece, and the latter from twenty-two to nineteen pounds the quarter. In order to recompense which, the animal comes to market four months earlier; the wethers at two years old, with advantage; that is, after being twice shorn as sheep, and once as lambs, equals the average already stated. This issue once more crossed with the new Leicesters, will arrive, it is said, still earlier to the same perfection.

In the Bampton nott breed, the wethers will, at twenty months old, weigh twenty-two pounds the quarter, and shear six pounds and a half of wool to the fleece; also the same sheep, well wintered, and kept on for another twelvemonth, will average twenty-three pounds the quarter, and yield eight pounds of unwashed wool to the fleece. The price of the wool at present is about 1s. the pound.

The first cross of this breed with the new Leicester is fast growing into great esteem in this district, in consequence of its improving the form, and bringing the animal three months sooner to market; but though so far useful and desirable, any more of that blood is thought disadvantageous, as rendering them too tender while young, and to require too much care and nursing.

The Bampton nott crossed with the new Leicester is also a sort much approved of in several parts of the county, especially when carried to the fourth degree, or four parts of the Leicester to one of the native nott. This cross, it is said, comes earlier to market, and at two years old will generally average twenty pounds the quarter, and eight pounds of yolk wool to the fleece, which is worth about 10d. the pound. And the old Leicester cross upon the Bampton makes a large and handsome animal, which feeds kindly and tallows well within. The wethers of two years old will average, with advantage, thirty pounds the quarter, and shear ten pounds of yolk wool to the fleece. It is much valued in some places. But the new Leicester cross upon the same sheep, will in some situations bring forward wethers at twenty months old, weighing twenty-two pounds the quarter, with a shear of eight pounds of yolk wool to the fleece, both of which are at this time worth 10d. the pound, weighing, according to the custom of unwashed wool, twenty-one pounds for every score. This sort is highly valued by some in different parts of this county. The half Bampton cross is more hardy than the new Leicester sort, and suits some places better.

## SHEEP.

*Exmoor Breed or Variety.*—This is a sort of sheep which is characterized by having horns, white faces and legs; by being very delicate in the bone, neck and head, or what is sometimes denominated deer-necked; by the form of the carcase being indifferent, narrow, and flat-sided. According to Mr. Culley, the weight *per* quarter in wethers at two years and a half old, is from 15lbs. to 18lbs.; and the weight of wool much less than in the Devonshire breed. It is a small breed of long-woolled sheep, principally produced on or in the neighbourhood of the moor from which it takes its name, which is in the northern extremity of the above county. Mr. Lawrence supposes that in their present state they are by no means to be considered as a profitable sort of sheep-stock, either in what relates to flesh or wool; on which account it would be for the interest of the county to change them for the best fine-woolled breed. It is remarked by Mr. Billingsley, that this breed of sheep is frequently kept two or three years, merely for the annual profit of their fleeces, which often do not exceed more than four pounds in weight; and that from their being kept upon very bare and indifferent pastures while young, they are supported by many sheep-farmers to be a very profitable sort of stock.

This horned breed has a moderately long staple of wool, which formerly, before the cloth manufacture of the county of Devon fled into Yorkshire, was much in demand by the clothiers of several different places. The fattened wethers of this breed, at three years old, will usually weigh about 15lbs. the quarter, and average 4½lbs. of washed wool to the fleece; which is worth at present about 13*d.* the pound. Attempts have been lately made in different places to improve the wool of this breed or sort of sheep, by a cross with the Merino or Spanish ram, and the results of the trials thus made are as below:

Quantity and value of native fleece	}	4½lbs. at 1 <i>s.</i> 1 <i>d.</i> <i>per</i> lb.	4 <i>s.</i>	10½ <i>d.</i>	
First crosses with the Merino	}	5 — 2 2	—	10 10	
Second crosses on this produce	}	5 — 2 9	—	13 9	
Third crosses on same	}	5 — 3 5	—	17 1	

In which improvement of the fleece the carcase is said to be rather advanced than the contrary.

In the crosses of the old Leicester upon the Exmoor breed, the wethers, which are the produce at three years old, average about 24lbs. the quarter, and carry 6½lbs. of yolk wool to the fleece. The Exmoor sheep have also been crossed with the new Leicester; the wether produce of which, at two years old, will weigh 18lbs. the quarter, and yield 6lbs. of unwashed wool to the fleece: the price of the two latter 9*d.* the pound. Much loss is often, it is said, sustained in this last cross at the time of yearning, in consequence of the great size of the shoulders of the lambs retarding or preventing their exclusion. This will, however, be remedied in the produce of this cross.

The Exmoor breed is a hardy sort of sheep on wet exposed land while young. The ewes under such circumstances, in lambing, are also superior to the Bampton nodd kind.

*Cornish Breed or Variety.*—The true breed of this sort is said to have grey faces and legs, coarse short thick necks, standing lower before than behind, narrow backs, flattish sides, a fleece of coarse wool, weighing about two or three pounds, of eighteen ounces each; their mutton, which is feldom fat, from eight to ten pounds the quarter.

However, from the various crosses which have been introduced into the county at different times, in consequence of

the use of rams of the Exmoor, Dartmoor, North and South Devon, Dorset, Gloucester, and Leicester kinds, the pure breed of this description is, it is said, now become rare, but that, from the inferior nature and value of its properties the total extinction of it need not be lamented. The district is now capable of supporting a much better and more improved breed of this sort of animal.

*Black-faced Heath Breed or Variety.*—This is a kind or breed of sheep which, according to Mr. Culley, have large spiral horns, black faces and legs, a fierce wild-looking eye, short firm carcases, from 12lbs. to 16lbs. *per* quarter, covered with long, open, coarse shagged wool, fleeces 3lbs. or 4lbs. each, wool worth at present about 8*d.* *per* pound. They are an active hardy sort, running with amazing agility, and best adapted, of all other breeds, to exposed, heathy, and mountainous districts; seldom fed until three, four, or five years old, when they feed well, and make the finest mutton, having a high-flavoured gravy. The sheep of this wild-looking breed are natives of the north-west of Yorkshire, and of that mountainous tract of country adjoining the Irish sea, from Lancashire to Fort William: they have been of late years introduced into the Western highlands of Scotland.

And the writer of the "Treatise on Live Stock," supposes the black-faced Linton, or short sheep of Scotland, to be a variety of the Heath sheep. They have been crossed with the Cheviot breed, and Mr. Culley, it is noticed, recommends a Dishley cross, meaning, doubtless, for the use of the low lands. If he may be allowed to give an opinion, he would, for upland situations, recommend a Spanish cross, with good winter management, in preference to all others. It is disgraceful, he contends, to the rural economy of Britain, that so excellent a breed of sheep should be needlessly compelled to brave the rigour of the seasons, in such loose, ragged, and beggarly clothing, when they might, with a few years' pains, and without any deterioration of the carcases, produce a fleece of high value and consequence to the manufactures of the country. And he adds, that Mr. Henry King, salesman of Newgate market, and an eminent grazier, informs him, that he once fed a lot of these northern heath sheep, and made excellent mutton of them, about 16lbs. a quarter; but that their wool hanging down their quarters like goat's hair, was so execrably bad, that it could be sold only for mop yarn.

But what are termed *black-faced*, or *short sheep*, are said to have been originally short-woolled, the present length of it having proceeded from crossing; and it is not well ascertained whether they are a native Scotch breed, or have been introduced from the moor-lands of Yorkshire. Besides the objection to these *black-faced* sheep, on the ground of the coarse loose nature of their wool, they are said to be subject to the *braxy*, a disease that was unknown in the Highlands before their introduction. And it is remarked, in the able Agricultural Survey of East Lothian, that the kind of sheep bred and most generally kept in Lammermuir, is the black-faced, or more properly, what is called the *brooked faced*, a sort of dirty-looking mixture of black and white; they are for the most part horned; when they are fed, the wethers weigh from 10lbs. to 12lbs. *per* quarter, and the ewes from 8lbs. to 10lbs. on an average. It will take eight or nine fleeces of the ewes and hogs, and six or seven of the wethers, to make a stone of seventeen pounds (twenty-one ounces to the pound); the quality, and consequently the price, vary much. The difference of quality may result from various circumstances; it is owing partly to the quantity of tar put upon the sheep in salving; partly, it is supposed, to the situation in which they pasture, as those fed on high grounds, and coarse mossy herbage, are thought to have inferior wool; and partly to the

general

## SHEEP.

general attention and care which farmers bestow upon their flocks, in which some are greatly superior to others. But the black-faced sheep seem, the writer thinks, to be capable of very considerable improvement; it does not, indeed, appear, that much has been done for improving that breed, which certainly places them in an unfavourable situation, when their merits come to be discussed in opposition to others which have received great attention. There can hardly be a doubt that the weight of the carcase and the quantity and quality of the wool might all be increased, by sufficient care to select the strongest, healthiest, and best feeding among them for the purpose of breeding. It has been observed, that those which feed best have the greatest quantity of wool, and generally of the best quality; and it is natural to suppose that it should be the case, as they must be the healthiest and strongest.

*Herefordshire, Rofs, or Ryeland Breed or Variety.*—This is a sort of sheep which is distinguished by the author of the “Treatise on Live Stock,” by the want of horns, and having white legs and faces; by being small in size; and the wool growing close to the eyes; by the carcase being pretty well formed; and by the excellence of the mutton. Weight *per* quarter from 10 lbs. to 18 lbs. Wool fine and short, the lean poor-fed sheep producing the finest. It is the true breed of this sort of sheep which is properly denominated Ryelands. In the Agricultural Report of that district, they are said, in symmetry of shape, and the flavour of the meat, to be superior to most flocks in the country. They lamb in February and March. It is a breed which, Mr. Knight says, is found to be remarkably easy in respect to food, but which, in its management, requires coting in the winter season, and being fed with hay or peas-haulm. In some cases they are housed all the year round in the night-time. The cots are low covered buildings, proportioned to the extent of the flocks. In the Herefordshire Agricultural Report, it is observed that the coting materially contributes to the health of the animal and the fineness of its fleece. The quantity shorn from each of the small original breed does not average more than two pounds; but the quality is such as almost to rival that imported from Spain. The price has often been as high as thirty-three shillings the stone of twelve pounds and a half untrinded, when the coarse wool has brought but ten or twelve shillings. They are said, by Culley, to fatten the best at four years old. The Archenfield, or true Herefordshire breed, is said to afford the finest wool, except the Spanish. It is suggested by Mr. Knight, that the disposition of sheep to fatten in the north-west part of that district is in the proportion to the fineness of the wool; but he is not certain of its being so in this breed; however, it seems to him that where the wool is close and fine, there are many advantages; less nourishment is drawn from the body in its support than in the contrary case. The long coarse-woolled fleece admits the rain more freely, and by dividing on the back lets it down to the skin. It also takes in a larger weight of water, which must more inconvenience the animal already heavily loaded. The fine close fleece of this breed admits the water with difficulty, even when immersed in it in washing, and is never wet through by rain. On account of the closeness of the texture, it only lodges on the outside, and is easily removed by the animal shaking itself. Besides, a fleece of this kind is much more warm and light. For these reasons it is supposed that no breed of sheep in the island is capable of subsisting on so small a proportion of food as this.

This animal, in Mr. Knight’s opinion, appears to be much more patient of hunger, and to keep itself in better condition on a less quantity of food than any other which he has had

an opportunity of observing. To the great scantiness of the pasture on which it is usually condemned to feed, is to be attributed the fineness of its fleece; for the quality of this becomes immediately impaired by a copious supply of food; and this circumstance should be attended to, in every county where these sheep are introduced.

Some attention has lately been paid to its improvement, and although the wool is somewhat less fine in its quality than it formerly was, it is still the finest in the island, with the exception of the Spanish sort recently imported; and the animal must be allowed, on the whole, to have been considerably benefited. The quantity of wool afforded by the improved sort of Ryelands, although increased, is still far from large; a three-years old wether rarely yielding more than three pounds and a half. But as a large number of sheep will subsist on a small portion of ground, and the wool is still worth two shillings and sixpence the pound, its value, compared with the quantity of food consumed by the animals, is probably much greater than that afforded by any other breed.

And the Ryeland sheep readily acquires, on a very moderate pasture, that degree of fatness which renders its flesh more acceptable, but it is wholly incapable of being loaded with fat in the manner of Mr. Bakewell’s. It appears to him to fatten somewhat more quickly than those he has seen of the South Down breed.

In the Agricultural Survey of Herefordshire it is suggested, that a cross between the Ryeland and real Spanish seems the most probable mode of adding to the fineness and value of the wool; and amongst many spirited breeders who are now making the experiment, colonel Scudamore of Kentchurch, sold the fleeces of a flock so crossed at forty shillings *per* stone, in the fair at Rofs, in the course of last year. The first stage of the cross materially detracts from the beauty of the Ryeland’s form, but by continued attention, this objection will probably be removed, and the flavour of the mutton is uninjured. Lord Somerville has found that they feed quickly, and weigh heavily, although their form be not attractive; but perhaps form in this animal is of little comparative consequence. An ox rarely fattens well, or has flesh of good quality, unless it be in one particular shape; but sheep fatten well, and the meat is of prime quality in those of very different forms. Two Leicesters which were fed by Mr. Hewer, of Abergavenny, and slaughtered before the Agricultural Society of this county in March last, weighed no less than fifty-one pounds in each fore-quarter, and forty-five in each hind-quarter. But notwithstanding this great weight, the Leicesters are often found less heavy than they appear to be, whilst the half Spanish weighs more than is generally expected from its size.

A cross of the Merino on the Ryeland breed has been tried in some parts of Devonshire with an appearance of success. The three-years old wethers of this cross, when fattened to their frame, being, it is said, estimated to run from fourteen to sixteen pounds the quarter, and to throw off from three pounds and a quarter to four pounds of washed wool to the fleece. In experiments made by some on this cross in other parts, it appears that two-years old wethers of the first cross will weigh about fifteen pounds the quarter, and shear from six pounds and a half to seven pounds of wool in the year to the fleece, which is worth 2s. 9d. the pound. The sheep are, however, greatly exposed to the foot rot.

The cross between the Ryeland and the Spanish has been made in some other parts, which has completely succeeded as to fleece, as the produce of the third cross of this breed readily sells for 3s. 6d. the pound; it is, however, objected to by many on account of its not affording an equal acreable proportion of mutton with the native sheep.

## SHEEP.

In crossing this breed with the Dishley, an useful kind of sheep has, however, been produced, both the wool and carcass being increased in weight, but much injured in respect to fineness; and it is contended by some, that the breed is rendered much less hardy by it.

*Warton Cragg Breed or Variety.*—This is a sort or variety of sheep which is principally met with in the district of the above name, and that of Silverdale, in the northern part of the county of Lancaster. These cragg sheep are greatly esteemed for the fine flavour of their mutton, their ready disposition to fatten, and the fineness of their wool. They are a close compact well-made breed of sheep, commonly with white or mottled black and white faces and legs. Their fleeces are short and close in the wool, which usually falls high. Their pasture is chiefly that of the poor short rocky lime-stone kind. They are deserving of more attention than has hitherto been bestowed upon them by the farmers of the neighbourhoods where they prevail.

*The Shropshire or Morf Breed or Variety.*—This is a sort which, according to the writer on live stock, has small horns, with speckled dark or black faces and legs; they have the full character of real fine-woolled sheep, and have been, for centuries, bred in Shropshire, Staffordshire, Worcestershire, and the vicinity. Their fleece is nearly all fine, and, it is said, superior to Ryeland wool, since the crossing which has taken place in that flock. Mr. Pitt, of Pendeford, in a letter to lord Somerville, dated 1799, estimates the extent of Morf common, or walle, at 3600 acres, and the number of sheep summered thereon, at 15,800, to the annual profit of fifteen shillings per acre in wool only, on a moderate calculation, eight fleeces and a half to the stone of 14 lbs. Nothing is reckoned on account of carcass, as the sheep have some extra keep during winter. It is added, that the Shropshire commons produce good fine wool, but none equal to Morf by sixpence a pound.

*The Dorsetshire Breed or Variety.*—This breed is known by having the face, nose, and legs white, head rather long, but broad, and the forehead woolly, as in the Spanish and Ryeland sorts; the horn round and bold, middle-sized, and standing from the head; the shoulders broad at top, but lower than the hinder quarters; the back tolerably straight; carcass deep, and loins broad; legs not long, nor very fine in the bone. Weight per quarter in wethers, at three years and a half old, from 16 lbs. to 20 lbs. Mr. Billingsley says, that the wool is fine and short. It is a breed which has the peculiar property of producing lambs at any period in the season, even to early as September and October, so as to suit the purposes of the lamb-sucker. It has been found to answer well in some of the midland districts, and, from its close make, to be equally advantageous with almost any other. It is, however, supposed capable of improvement by being crossed with rams of a larger size. There are varieties of it met with in several districts. And it is said by some, that the Dorset breeders pay great attention to preserve the colour of their flocks from mixture, since white lambs are the most esteemed in the London markets, from a presumed superior delicacy in the meat. It is believed this is one of the best breeds in England, if not superior to all others, considering its various qualifications. Their property of bringing twins, and making our highest priced house lamb, must be considered first; they are both good hill sheep and pasture sheep, and their flesh is an excellent medium between the delicate mutton of the hills, and the rich and juicy meat of the best lowland sheep. The later Dorset lambs, when fattened, make the earliest grass lamb. By the practice of this county, the lambs which the breeders retain are shorn at Midsummer, having been taken from the ewes in May; produce of wool, one pound to a pound and a half each, the

price a penny per pound nearly, under the price of sheep's wool. A three-shear sheep may produce four or five pounds of mid-dling fine wool, which it would be highly advantageous to improve to the utmost, on this excellent breed.

This is a breed, or sort of sheep, which seems to prevail among the generality of farmers in the high lands, and some other parts of the county of Devon, which border on the above, in which they are found to answer very well.

And there is a breed or variety nearly connected with these in the Mendip hilly district. They are smaller than that breed, having smaller horns, more deer-headed, the wool less in weight; the mutton excellent in its flavour. It has been observed by the author of the "General Treatise on Cattle," that in the West Riding of Yorkshire, and in the adjoining parts of Westmoreland, they have a breed of horned and white-faced sheep, bearing a strong affinity to the Dorsets; they are called *Craven* and *Wensleydale* sheep, but more generally *Peniston*, from the market town where they are sold. They are a good down or hill sheep, in their pure state, and give a fleece of coarse short wool, weighing between two and three pounds, the carcass good mutton, about fifteen pounds per quarter. They are variously crossed in that riding, with Cheviot, Dishley, and Northumberland tups; with the two last, for the purpose of making pasture sheep, in which case the weight of carcass is increased to twenty or thirty pounds per quarter. In the north, this breed is commonly crossed with the Heath sheep, which gives them black or grey faces and legs, with sometimes a black spot on the top of the neck, the wool coarse and open, instead of being close and thick set upon the skin, as a defence against the severity of the climate of that hilly and exposed country in which they are fed; defects for which the remedy is obvious. Ryeland tups have been tried with the Peniston ewes, a cross which made a considerable improvement.

*The Wiltshire Breed or Variety.*—This is a sort which has sometimes the title of *horned-crocks*. The writer on live stock distinguishes the breed, as having a large head and eyes, Roman nose, wide nostrils, horns bending down the cheeks, colour all white, wide bosom, deep greyhound breast, back rather straight, carcass substantial, legs long, bone coarse, fine middle wool, very thin on the belly, which is sometimes bare. He supposes, with Culley, that the basis of this breed is doubtless the Dorset, enlarged by some long-woolled cross; but how the horns come to take a direction so contrary, is not easy, he thinks, to conjecture; he has sometimes imagined it must be the result of some foreign, probably Tartarian, cross. The old Hertfords were, he says, supposed a kindred breed with the Wilts, but at present, the few of this kind bred in Herts are of smaller size, longer and coarser wool. These large and leggy Wilts' sheep work well in the fold, and have always had the character of good thrivers at corn, oil-cake, and the best meat, making very large mutton, and very deep in flesh, which is high-flavoured, yielding the dark-coloured gravy. The breed is, he adds, every where on the decline, generally supplanted by the South Downs, of which the farmers find they can, on the same quantity of land, keep more than one and a half, for one of the Wilts, the former, moreover, producing both better mutton and better wool. The disease called the *goggles*, is said to be peculiar to the Wilts sheep. It is stated, that this breed has been long used, more or less, in the counties bordering on Wilts, and in Surrey, Kent, Herts, Essex, and Middlesex. But that it is a breed not worth preserving; perhaps the only thing to be done with it to advantage, is to cross it with the Merino. The Hampshire variety of this breed is said, for what reason he knows not, to be more hardy. It is a breed, however, which is esteemed in some places.

## SHEEP.

*The Berkshire Breed, or the Variety called Notts.*—This is a sort which the same writer describes by having considerable length and bone, straight made like horses, full fore-flank, Roman faced, with distinct black spots, high on the leg, thick fleece, of considerable length. He supposes them to class with the long-woolled breeds, and to probably bear some affinity to the breed of Oxfordshire, which is, he is told, a peculiar variety.

The peculiar qualities of the Berkshire nott breed seem to be its great size, height on the legs, and weight when fattened. It would appear, contrary to the opinion of some, that this breed is well suited for the strong low lands of its native district, though the South Down sort are fast supplanting it in many places, probably without sufficient experience of them in such situations. In contrasting them with the horned Wiltshire sheep, it is found by some that the polled Berkshire or nott sort are as certainly more properly adapted to the low and cold lands, as they are proved to be more hardy for the fold, to fat sooner, and to be less liable to injury from the fly, than the horned sheep. When fat, the sheep vary as much as from fourteen to forty pounds the quarter, in weight. These polled or nott sheep are, however, not of so large a size as the horned sort of the same district. The fleece of this breed of sheep is not fine, and on the average it will take eight of them to a tod of wool. The mutton is rather coarse, as in all large breeds of animals. The utility of crossing this breed is by no means decided. Some advise to breed from the best of this sort, but to cross for fattening. Crosses are, however, very common between many different sorts, as between the notts and the Wiltshires, the Cotswolds, the Leicesters, and different mixed breeds.

The Berkshire nott breed is much valued in some parts of Oxfordshire, especially for regular breeding as well as standing the fold. They are strong, active, and able to travel, and fold unusually well; against which good qualities they are, however, long in fattening, &c. The crosses with the Leicester improves them considerably, still they are fast giving way to the South Down and some other breeds.

And it is observed in the Norfolk Agricultural Report, that the Wiltshire sheep have proved, in various trials, an unprofitable breed, as well as the Norfolks; but it is remarkable that for turnips, no sheep are said, by many practical and experienced husbandmen, to pay better, if so well. In Hertfordshire, many who turnip-feed adhere to that breed, who admit the South Downs to be a superior sort for grass-feeding.

*Heath-Croppers or Windfor Forest Breed or Variety.*—This is a small ill-shaped breed of little value, found abundantly in the parishes which lie within the precincts of the forest of Windfor in Berkshire. It is a breed which affords a very sweet kind of mutton. A quarter of it will weigh about twelve or fourteen pounds. And in regard to the wool, about thirteen fleeces will make a tod. It is of equal value with that of the South Down breed. The term *heath-croppers* is very commonly, though vulgarly, applied to sheep of this breed.

*The South Down Breed or Variety.*—This is a very valuable sort of sheep, which Culley has distinguished by having no horns, grey faces and legs, fine bones, long small necks, and by being rather low before, high on the shoulder, and light in the fore-quarter, sides good, loin tolerably broad, back-bone rather high, thigh full, twist good, mutton fine in grain, and well-flavoured. Wool short, very close and fine, in the length of the staple from two to three inches. Weight per quarter in wethers at two years old 18 lbs. It is a breed which prevails on the dry chalky downs in Sussex, as well as the hills of Surrey and Kent, and which has lately

been much improved both in carcase and wool, being much enlarged forward, carrying a good fore-flank; and for the short less fertile hilly pastures is an excellent sort, as feeding close. The sheep are hardy, and disposed to fatten quickly; and where the ewes are full kept, they frequently produce twin lambs, nearly in the proportion of one-third of the whole, which are, when dropped, well-woolled. The wethers are capable of being disposed of at an early age, being seldom kept longer than two years old, and often fed at eighteen months; which is a very valuable property. But according to the Sussex Agricultural Survey, the ewes are commonly kept till between four and five, and found to answer well to the graziers in the neighbourhood, as well as the farmers in Norfolk and the adjoining counties, in the place of home-bred sheep, as being more expeditious feeders, and equally adapted for the purpose of the fold. It has been observed, that it is in fact a breed of sheep which, from the compactness of their form, and their legs being shorter, considerably outweigh both the Dorset and Norfolk breeds, in proportion to the size of the carcase, being heavy in a small compass. Their hardiness is estimated according to the darkness of the colour in the face and legs; but as there is inconvenience in the produce on this account, from the wool, especially about the head and neck, becoming spotted with black, and thereby thrown aside by the flapler, as only of half the full value, a middle degree of colour may be best. As an open country breed, they are sufficiently gentle and tractable. They are capable of travelling well, and of resisting the effects of exposure to cold. The wool is scarcely, if at all, inferior in fineness to that of the Herefordshire kind; as the practice of sorting, which is common in that district, is not in use on the Downs. The excellent properties of this breed have been brought fully to the notice of the farmer, by the great patrons of improvement in Bedfordshire and Norfolk, and its superior merits on trial have been such as to have induced the sheep-farmers in various districts to introduce them in preference to other breeds. It is stated, in the Annals of Agriculture, that they have been found to consume less food, in proportion to weight, than the Norfolks, yet keeping in better order. Young sheep produce the best lambs; the crones are of course constantly sold at four or five years old; and if it were done earlier, it is supposed, it would be more profitable. The author of the "General Treatise on Cattle" suggests, that the most noted variety is that of Mr. Ellman, of Glynd, in Sussex, who, he believes, first enlarged the Down breed, by the aid of polled or *nott* Berkshire tups. From this enlarged cross, he understands, originated the stocks of the duke of Bedford and Mr. Coke; the South Downs of Mr. Coke being generally acknowledged the largest and finest in England, a very pregnant proof of which was given at lord Somerville's cattle show, in a two-shear Holkham South Down wether, which weighed more than 40 lbs. per quarter. Although quick and early feeders, they tallow within remarkably. And in answer to the complaints of those who knew the old Down sheep, that their wool is become so much coarser than formerly, from the modern habit of feeding the sheep with rape, cabbage, and oil-cake; they seem totally to forget the middle and long-woolled crosses, by which the carcase of the South Downs of the present day has been enlarged, and their weight of wool increased, and rendered more coarse. The mutton is still excellent, although probably not so high-flavoured as the old Down mutton. It is also further suggested, that it would be difficult to point out any part of the island for which this breed would be unfit, but extremely easy to name a vast number of districts where it would be a most advantageous substitute for the native flocks. It is supposed, that all the

## SHEEP.

South Downs want is the noble covering of a Spanish fleece, and how little their carcase would suffer by the crosses, has, it is said, been demonstrated by lord Somerville, in the exhibition of a very fine ewe, large enough for any purpose, half Spanish and half South Down. But in order to form a comparison between the Norfolks and South Downs, Mr. Overman of Norfolk, on March 27th, 1799, took from turnips twenty-four two-years old Norfolk wethers, and ten South Down of the same age, having always lived together from the time they were lambed, and two hours afterwards they weighed as follows:

Besides, these Norfolk sheep losing 11 lb. 10 oz. more of their respective weight (taken full and empty) is a strong circumstance against them. The Downs are run much thicker on the land than the Norfolks. And Mr. Hill of the same district estimates the difference of stocking between Norfolks

and South Downs, at one-third in favour of the latter, in number, in better condition, and of greater weight, both in wool and carcase; all fairly attributable to the superiority of the breed, and free from any charge of lessening cattle, &c. When his flock was of Norfolks, scarcely one in a score had a whole fleece; but now they are South Downs, scarcely one in a score is broken. And Mr. Blythe of Burnham had, four years ago, a flock of between five and six hundred Norfolks: he has now one thousand South Downs on the same land, and has likewise double the wool from his land stocked with South Downs, to what he clipped when under Norfolks. Also Mr. Durgate, who has had South Downs six years, is clear that, free from all change in husbandry, or other circumstance that would unfairly affect the comparison, the number kept, compared with the Norfolks, has been as five to four. The carcase is as heavy as the Norfolks, more wool, and a better price. He does not fold; but the South Downs would bear it better than the Norfolks. At Palsgrave he folds the South Downs, because there is a sheep-walk; a Norfolk flock changing gradually to South Downs.

Some think that the South Down are much superior to the Norfolk, Cambridgeshire, and west country sheep, both in point of form, hardiness, fineness of wool, and disposition to fatten. Crosses of the South Down with other sorts are likewise much approved of in many places; as that of the South Down ram with the Norfolk ewe, the lambs of which cross are sometimes greatly admired. Some suppose it equally beneficial when done with several other breeds, according to the circumstances of the different districts. But this sort of crossing is very sparingly practised in the native district of this breed of sheep. It has been tried with Spanish rams, and the wool has been considerably improved by the attempt; but two great defects, not to be compensated by any improvement in the wool, are said to be produced, which are tenderness of constitution, and badness of shape. In other places this has not, however, been noticed to take place. In Oxfordshire, and several other counties, the South Down breed is fast supplanting the Berkshire, Norfolk, and many other kinds.

And it is stated, in the Staffordshire Agricultural Survey, that the Cannock Heath are a sort of sheep that has much resemblance to this breed, and is believed to have originated from the same. It is stated to have been much improved in the form, thickness, and weight of the carcase, as well as the fineness of the wool, by crossing with rams of the Herefordshire breed. They are polled with grey faces and legs; low before; wool fine and thickly set, weighing two or three pounds the fleece; the mutton good: they weigh from 15 lbs. to 20 lbs. the quarter. In sir Edward Littleton's improvement of this breed, by crossing with Herefordshire tups, the carcase and wool were both bettered, the latter being rendered worth nearly 2s. the pound.

*The Norfolk Breed or Variety.*—In this sort of sheep, the face is black; the horns large and spiral; the carcase long, small, weak, and thin; narrow chine; large bones; very long black or grey legs; mutton fine-grained and high-flavoured, but does not keep well in hot seasons. The weight per quarter from 16 lbs. to 20 lbs. The wool in the best part short and fine, but part coarse. This breed is chiefly prevalent in Norfolk and Suffolk, where folding is much the practice, as they have the property of travelling well. They are found in disposition to be given to be rest-lets, which renders them unfit flock, except in good inclosures. And it is stated, in the nineteenth volume of the Annals of Agriculture, that this sort of sheep, from possessing few valuable properties, in addition to that of stand-

## SHEEP.

ing the fold well, and as requiring much expence in winter keep, an acre of turnips being the usual allowance for half a dozen besides hay, has lately given way to the South Downs, which are supposed by some to be hardier, less nice in their food, sooner ready for the fold, and more quiet. This last sort has lately gained much ground. The wool might be improved by a Spanish cross, but little other advantage would be gained. It has been remarked, in respect to the quick *tainting* of this mutton, by Mr. Vyfe, butcher of Eaton college, that the Norfolk mutton certainly will taint sooner than any other, in very hot weather; neither is there any sort (that he knows) of a worse flavour at that time, though inferior to none in cool weather. Many very fine and fat Norfolks do not please on the table. The fat runs away in roasting, if they are laid to a hot fire; and they rarely are so sweet as the South Downs. The latter are in hot weather worth a halfpenny a pound more than the Norfolks. When both are *completely* fatted, it is hard to say, (supposing the season cool,) which upon an average is fattest; the flavour too, in such a season, he thinks, is equal, and as to coarse meat, there is none in either sort. But if they are killed in cool weather, before they are very fat, the preference must be given to the Norfolks, because the meat will in that case eat better, and there is a probability of much more fat within. With respect to profit to the feeder, if they are fed entirely with grass and upon good land, his opinion is decidedly in favour of the South Downs; or if they eat turnips in the winter, and after that are kept two or three months upon grass in the spring, it is the same; but if they are half fat against winter, and are to be completed at turnips, he believes no sheep are more profitable than Norfolks, perhaps none so much so. But both sorts should be kept where there is both turnip and grass land. There are varieties of this breed in Cambridge and Suffolk, with coarse wool, and weighing about 18 lbs. or 20 lbs. the quarter.

Crosses of the Norfolk, with the South Down and many breeds of other kinds, are met with and highly valued in different situations.

A great diversity of opinion prevails, in regard to the superiority of the Norfolk and the South Down, which has led an experienced sheep farmer, at Finchfield in Essex, to make the very accurate trial which is detailed below. In September 1791, he purchased in Suffolk a lot of ewe lambs, at 6*l.* 10*s.* the score: and in Suffex, in the October following, a lot of South Down ewe lambs, at 13*l.* the score. These lots of sheep were depastured together, and received in every respect the same treatment until the 25th of the same month in 1793; when a single sheep, which was adjudged to be the level of each lot, was taken out, and after both of them had fasted twenty-six hours, they were weighed alive, the South Down weighing 96 lbs. and the Norfolk 95 lbs.: they were then killed, and the results of the trial were as follow.

It is noticed, that neither of these ewes had any lambs, but at the time of trial, the Norfolk was more than half-gone with lamb, and the South Down had but just taken the ram.

In short, the leading and characteristic qualities of the high and full-bred Norfolk and South Down sheep, seem upon comparison to be chiefly these, the wool of both is found to be of the first clothing quality, but the larger quantity is produced by the South Down: the mutton of both is equally delicious. But the quiet gentle South Down in the pasture, must be opposed to the wild impatient ramblings of the Norfolk, whose constant exercise not only excites continual appetite, but at the same time occasions considerable waste in the pasture, by treading down and unnecessarily spoiling a great deal of food they do not eat. For this extraordinary exertion on the part of the Norfolk sheep in thus, as it were, wantonly destroying a large portion of food which is prepared for its subsistence, there does not appear, from the trial already noticed, to be the smallest occasion at least, to put it on an equal footing with the South Down in that particular; for it is evidently demonstrated by that trial, that in an equally sized sheep, the heaviest, and most capacious stomach, and consequently requiring the greatest quantity of food, is found to appertain to the Norfolk sheep. The hardness of the South Down, enduring wet and cold lodging, and a greater degree of abstinence and fatigue than the Norfolk in the fold, is a superiority of much moment; and only to be equalled by another, which they possess in a very superior degree, which is that of doing well upon coarse four pastures. These are fairly to be contrasted with the delicate constitution, and the tender aromatic herbage, required by the Norfolk; to all which it may be added, that the South Down is an equally good turnip sheep; and for every possible purpose, whether for its flesh, for its wool, for breeding, for folding, or for the butcher, they demand a less supply of food, and of an inferior quality to that which, in every situation, would appear indispensable to the well doing of the Norfolk. On the score of the first cost of these sheep, an objection may, it is said, be very justly stated as to their general use; but when the South Down are more generally bred and increased through the country, in that proportion will the present objection be done away; and though they may continue in equal estimation, they will nevertheless, by their being more generally diffused and increased every where, be brought to a more equal level, in point of price, with the Norfolk, Welsh, and all those breeds so justly held in requisition for the fineness of their wool, and the superior excellence in the flavour of their mutton.

The value of the crosses which have been made between the Norfolk and Welsh sheep, by the South Down rams, are far from being decided, some sheep-farmers thinking them

## SHEEP.

them highly beneficial, while others strongly reprobate them.

*Delamere Forest Breed or Variety.*—This is a breed or sort of sheep, which is found about the forest of that name, in the county of Chester. In point of shape, the animals are said not to be unlike those of a diminutive Norfolk sort, having the faces and legs black, grey, brown, and white, generally with small horns. The breed is small, the wethers not weighing more than from 8 lbs. to 12 lbs. the quarter, at four years old. The mutton is in common much esteemed, and the wool is valuable, selling about the year 1808 at 2*l.* 12*s.* 6*d.* the stone of 20 lbs.; the fleeces are, however, small, often not weighing more than 2 lbs. The wool is commonly purchased by the manufacturers of cloth in Yorkshire.

*The Herdwick Breed or Variety.*—This is a breed which is characterized by Mr. Culley by having no horns, and the face and legs being speckled; the larger the portion of white, with fewer black spots, the purer the breed; legs fine, small, clean; the lambs well covered, when dropped; the weight *per* quarter, in the ewes, from 6 lbs. to 8 lbs.; in the wethers of four years and a half old, from 9 lbs. to 12 lbs.; the wool short, thick, and matted in the fleece. It is a breed peculiar to the elevated mountainous tract of country at the head of the river Esk, and Duddon in Cumberland, where they are let in herds, at an annual sum: whence the name. At present they are said to possess the property of being extremely hardy in constitution, and capable of supporting themselves on the rocky bare mountains, with the trifling support of a little hay in the winter season; scratching down to the heath, during the snows, for their subsistence; and by their constantly moving about, not being liable to be drifted over by snow. From the nature of the climate, the ewes produce their lambs late, and are generally kept as long as they produce lambs. But the wether stock is usually disposed of from the mountains, without being put in the pastures, at from four to five years old. It is observed, that the fleece in this breed is finer than that of the Heath sort, but coarser than any of the short-woolled breeds. It is a breed that stands in need of a cross with some of the finer-woolled breeds, and the Spanish has been suggested as proper for the purpose. The property of the flocks, as well as of the mountains, is in lord Muncaster, the lord of the soil; and the farmer of the principal flock is now Mr. Tyson, whose family, it is said, have inhabited this wild and sequestered spot through four centuries. Mr. Tyson is a tup breeder, and sells a number of Herdwick tups yearly, some at several guineas each, to the adjoining districts, where their known hardy qualities are desirable.

*The Cheviot Breed or Variety.*—This breed of sheep is known by the want of horns; by the face and legs being mostly white, and the eyes lively and prominent; the belly long; little depth in the breast; narrow there and on the chine; clean, fine, small-boned legs, and thin pelts; the weight *per* quarter, when fat, from 12 lbs. to 18 lbs.; the wool partly fine, and partly coarse. Mr. Culley considers this as a valuable breed of mountain sheep, where the herbage is chiefly of the natural grass kind, which is the case in the situations where these are found the most prevalent, and from which they have obtained their name. It is a breed which has undergone much improvement within these few years, in respect to its form and other qualities, and has been lately introduced into the most northern districts; and from its hardiness, its affording a portion of fine wool, and being quick in fattening, it is likely to answer well in such situations. The Spanish and South Down have been advised as proper crosses for this sort of sheep.

And it is observed by the writer of the Argyleshire Report, that the Cheviot sheep are in every respect superior to the black-faced kind, and found to be equally fit for a mountainous situation. They are hardy, fine-woolled, and well-shaped. They are long-bodied and long-limbed, which fits them for climbing steep mountains, and for travelling, either for seeking their food, or going to a distant market. Their fleece, too, is finer, closer, and warmer. They have every property that should be sought in a mountain sheep, and accordingly they have been found to thrive in every part of the Highlands in which they have been tried, and are said to be less subject to diseases than the black-faced kind. Some of them have been lately introduced into the county by the duke of Argyle, and by Mr. Campbell of Auch, in the highest parts of Glenurchay, and found to answer exceedingly well. And lord Breadalbane, a few years ago, made a present of some Cheviot wedders to several of his tenants in Glenurchay, in order to try how they would fare on the same pasture with the black-faced kind; and the writer was informed by some of the store-masters, that they perceived no difference in their thriving. Indeed no part of this county is more inclement than that from which they came, where the hills are sometimes covered with snow for three or four months in a year, and where many of the lower walks consist of peat-bogs and deep morasses; so that with us their situation would be mended, a circumstance which will always ensure success.

It is likewise stated in the twelfth volume of the Statistical Account of Scotland, that the following experiment, made in the parish of Barr, in Ayrshire, shews the comparative hardiness and value of the Cheviot breed. In June, 1792, a ram and two score of ewe hogs, of the Cheviot breed, were put upon one of the highest and coldest farms in the parish. The harvest was wet, the winter and spring stormy, and the loss of the native sheep, through poverty and disease, was considerable; yet all these, though strangers, and in such a situation, did well. The wool of the native sheep, taking ten fleeces to the stone (24 lbs.), sold at 7*s.* 6*d.*; the wool of the Cheviot kind, taking only seven and a half to the stone, sold at 15*s.* The profit here was great; but how much more, if the wool had fetched its real value of 20*s.* the stone! And in "The Observations on different Breeds of Sheep," it is stated that in 1792, the Cheviot wool sold from 18*s.* to 20*s.* the smeared, and from 20*s.* to 22*s.* the white; from six to eight fleeces of the first, and from eight to nine of the last, going to the stone. Some went as high as 23*s.*; and it is thought it will soon be improved so as to fetch 30*s.*, if not 40*s.* Draft ewes sold from 12*s.* to 16*s.*, and three-years old wedders from 18*s.* to 22*s.* In Etterick, Ewisdale, and Liddesdale, they are now converting their flocks as quickly as possible into the Cheviot breed. The Roxburgh Agricultural Report also says, that Liddesdale is the worst district, yet the Cheviot breed thrive in it. The writer of the first of these Reports remarks, that it is difficult for those who have already got another kind to change the breed; but new beginners ought undoubtedly to stock with the Cheviot kind. It is said that the Yorkshire graziers have a prejudice against this kind; probably because they would then have more rivals in the trade, which is now in few hands; as the carcase, and not the wool, is the principal object of attention. Whatever there may be in this, the introduction of the Cheviot, which would treble the price of wool, would more than balance it. And he adds, from the same volume of the Statistical Account of Scotland, that even they who have another stock, and cannot conveniently change it, might at least cross it with the Cheviot breed, which might

be done with little trouble, and to great advantage. In the years 1787, 1788, and 1789, an intelligent farmer, in the parish of Moffat, put Cheviot rams to his black-faced ewes. In 1790 he sold the wool of the sheep produced by that cross at 10s. the six fleeces; and the wool of his other flock of the black-faced kind, which went exactly on the same pasture, only at 6s. 3d. the seven fleeces. The sheep thus produced were as healthy as his other sheep, the carcass not materially altered, and the weight of the wool increased a seventh part, and its price more than a third. The farm on which they were is as high ground as almost any in Scotland.

And the sheep which are at present known by the title of *Long Hill Sheep*, by the northern farmers, are a hornless, white-faced, loose-shaped breed, having a coat of ordinary short or fine wool, perhaps raised by crossing, through time, the old country breed with those of the Cheviot kind. They are said to be more tender than the short or black-faced breed, but to answer well with good care and keep. However, from the practice of milking ewes of this breed, for the purpose of making cheese, being found to be prejudicial, it has lately been much left off by the best sheep-farmers in these districts.

*The Dun-faced Breed or Variety.*—This is a sort which Culley says has no horns; the face in common of a dun tawny colour; the size small; the tail short; the mutton fine in texture; the weight often only 6 lbs. or 7 lbs. the quarter; the wool variously streaked and blended with different colours, some of which is very fine. He supposes it to partake of the Spanish breed, but it is not so hardy as the Cheviot breed. The mutton of this breed is excellent in flavour. They are supposed by some to have had a Spanish origin; but they have been naturalized, for a great length of time, on the Grampian and other hilly districts in Scotland.

*The Shetland Breed or Variety.*—This is a small breed, and mostly without horns; but what more particularly distinguishes it from other breeds, is the uncommon smallness and shortness of the tail; the weight per quarter from 7 lbs. to 10 lbs.; the wool very fine, and of various colours. The breed is very hardy, but much too wild in its disposition to be confined in inclosed pastures, and of course less proper for the purposes of the grazier. There is a sort of this breed of sheep, which, according to Mr. Johnson, carries coarse wool above, and fine soft wool underneath; and the sheep have three different successions of wool annually, two of which resemble long hairs rather than wool, and are by the common people termed *fors* and *scudda*. As soon as the wool begins to loosen at the roots, which is mostly about February, the hairs or *scudda* spring up; and when the wool is cautiously pulled off, the tough hairs continue fast, until the new wool grows up about a quarter of an inch in length, then they gradually wear off; and when the new fleece has acquired two months' growth, or thereabouts, the rough hairs, termed *fors*, spring up and keep root, until the proper season for pulling it arrives, when it is plucked off along with the wool, and is separated from it, at the time of dressing the fleece, by an operation called *forfing*. The *scudda* remains upon the skin, as if it were a thick coat, a protection against the inclemency of the season. But the native or kindly breed, that bear the soft cottony fleeces, according to Mr. Culley, are rather delicate; though the fact of their eating the sea-weed greedily, when the ground is covered with snow, and often during long and severe snows, when they have little else to live on, seems to prove the contrary. Nature, he says, seems to have imparted to them a perfect knowledge of the times at

which this food may be procured; for immediately upon the tide beginning to fall, they in one body run directly down to the sea-shores, although feeding on hills several miles distant from the sea, where they remain until the tide returns, and obliges them to seek their usual haunts. They are very hardy, and the wildest of all the breeds of these animals.

But in respect to the wool of these *beaver* sheep, as they are sometimes termed, it is short and open, and destitute of a covering of long hairs. These fine soft fleeces are liable to be rubbed off during winter, or early spring, which, it is supposed, might be prevented, by clipping the sheep in the usual way, instead of the absurd mode of pulling them off, which tends to weaken the sheep, and decrease the length of the staple of the wool. In regard to colour this wool is various, as *silver grey*, which is the finest and softest; the pure *white*, which is mostly of the greatest value for all the purposes of the finest combing wool; the *black*, and the *mourat* or *brown*, which are very little inferior: the whole of the softest texture, fit for the finest manufactures, and in some instances rivalling even Spanish wool, than which it is somewhat longer in the staple, and not so elastic. And it is stated to have been manufactured into stockings of extraordinary fineness; and that the fleece attached to the skin affords a fur of great value. This breed was formerly a native of the higher parts of Aberdeenshire, and in the districts to the northward of it; but it has been since much crossed, and it is now mostly confined to the Orkney and Shetland isles, the purest breed being to be found in the latter. The number of the *beaver* sheep in these isles amounted to ninety thousand, some years since; and five or six of them are said to be capable of being fed with the food required for one English sheep. In the West Riding of Yorkshire, Mr. Beaumont is said to have made a trial of these sheep; the result of which was, that they did not fat, but grow, which shews that their size would improve with that of the soil: their wool also improved in length. But the original old breed of the Highlands are said to partake of the nature of the goat and deer; their coat consisting of a sort of fur or down, covered by long, straight, rigid hairs, like those of the beaver, rather than wool; tail short, slender, tapering, not larger than that of the deer or goat, and thinly covered with strong, silvery hairs; the face covered with sleek hairs, like the face of the deer, with his prominent eyes. They are tame, delicate of frame, and requiring to be housed in winter: their flesh of high venison flavour. The breed is found in its original purity, in the central Highlands, on the southern banks of Strath Tay, and between those and Strath Brand; and on the banks of Loch Ness, in the northern Highlands, as well as in the Shetland islands.

*The Merino or Spanish Breed or Variety.*—In this breed of sheep the males have horns, but the females are without them. They have, according to lord Somerville, white faces and legs; the body not very perfect in shape; rather long in the legs; fine in the bone; a degree of throatiness, or production of loose pendulous skin under the neck; and the pelt fine and clear; weight, when tolerably fat, per quarter, in the rams about 17 lbs., in the ewes 11 lbs.; the wool very fine. It is a breed that is asserted by some to be tolerably hardy, and to possess a disposition to fatten readily; but others maintain the contrary opinion.

His majesty took the lead in the introduction of the Merino breed into this country, and his first flock was imported in 1792; but other nations seem to have got the start in this respect, as Sweden had them even in 1723, where they have since greatly increased; and in France, Germany, and some other

## SHEEP.

other states, they were probably known long before. They have lately spread much in this country, and been greatly improved in different respects, by judicious crossing with other sorts. The horns in the true Merino rams are now of a middle size; the faces and legs darkish-white, the latter rather inclined to be too long. The wool is uncommonly fine, and weighs about  $3\frac{1}{2}$  lbs. to the fleece, not being liable to deteriorate in this climate. The fleeces have a dark brown tinge in their surfaces, formed by dust sticking on the greasy yolk property of its pile; the contrast between which and the rich white coloured wethers, and the rosy hue of the skin, is very striking on the first view.

Some cross the Merino rams with Devonshire ewes, but the Ryelands are more commonly preferred. They consider five crosses as necessary for reaching perfection; and on that ground properly conclude, that the wool of the first cross can only reasonably be supposed to be worth about 7*d.* the pound more than that of the maternal flock, on the idea that it will, in five crosses, be of the value of 3*s.* above that of the Ryeland ewe; making an improvement of about 7*d.* in each cross. And that if the wool, when this sort is mixed with the most valued native breeds, does not gain its necessary degree of fineness in less than five crosses, it is unreasonable to expect the full price for it at one cross. It is, however, certain that the animal is improved by a mixture with the Ryelands, and that the wool will not ultimately be found inferior to that of the Spanish flock. The Spanish crosses with the South Down and Ryeland, in several degrees, is diffusing itself in many districts with great benefit. With the latter, in Devonshire, the wether produce, at two years old, weigh 15 lbs. the quarter, and afford a fleece of 5 lbs. each, worth 3*s.* the pound. In other cases, the weight of mutton is greater in the first cross; and the shear of wool from  $6\frac{1}{2}$  lbs. to 7 lbs. in the year to the fleece, at the same age. Crosses with some other fine-woolled breeds are likewise made with great utility.

But according to Dr. Parry, who has had great experience of this breed, they are, as stated in a late work on Live-stock, entirely enveloped in wool, which grows under the jaws, down the forehead to the eyes, under the belly, and down the legs to the very feet. It is astonishing to see how thickly it covers the skin; it will scarcely give way to the pressure of the hand, but yields as it were by starts, like the close short hair of an extremely fine clothes-brush. In washing them, the water penetrates to the skin with great difficulty. The fleece is heavier, in proportion to the carcase, than that of any other known breed in Europe. In the raw state (unwashed on the sheep's back or afterwards), the fleeces of the two-years old ewes average at  $4\frac{1}{2}$  lbs. avoirdupois, and the weight of the living ewe being about 60 lbs. the proportion of wool to that of carcase is about 1 lb. to  $12\frac{1}{2}$  lbs. The fleece of a fat wether of the same age will be from 5 lbs. to 7 lbs. In eight shearling rams, weighed alive, after having been clipped, the weight of the fleece to that of the living animal, was as one to about twelve and three quarters. The wool from the head and behind the ears, and the rest of the refuse, generally called *daglocks*, had been previously taken away. It is added, that had these sheep been washed before shearing, their fleeces would have lost about a ninth part. And that the length of the staple or filaments varies. In a shearling ram, shorn when a lamb, a sample of the wool cut close to the skin above the shoulder, was three inches and a half in length; and that of the breech, or middle of the back part of the thigh, three inches and three quarters: of an ewe of the same age, about a quarter of an inch shorter: the average according very exactly with

the specimens taken from newly imported Spanish sheep. An instance of the extraordinary length of staple, of four inches and three quarters, is related, which from the scoured fleece produced a sample more than five inches long. The proportion of fine wool in the fleeces of the Spanish sheep is much greater than those of any pure English breed. Thus, while in the Ryeland, which is probably divided into four or five sorts, the finest wool from the neck and shoulders does not make above one-eighth part of the whole fleece: in that of his majesty's flock, the fine wool formed near four-fifths of the whole. It is farther observed, that of Dr. Parry's wool, consisting of whole fleeces taken from sheep which had not more than three or four crosses of the Spaniard, and divided into three sorts (R. F. T.), according to the Spanish method,  $155\frac{1}{2}$  lbs. produced of R. or Rafinos, or superfine, 104 lbs. more than two-thirds of the whole. And the uniformity of fineness in the improved wool is such, that in shewing specimens from these different parts of the same animal, (the shoulder and the breech,) which are generally considered as producing the best and the worst wool; the doctor never met with any three persons who could agree which was the finest, and many good judges actually decided in favour of the latter. This wool contains a great deal of yolk, or oil, which is apt to entangle the dust of the fields, so as often to form a kind of mat of nearly an inch in thickness; it is remarkably, or rather wholly free from litchel hairs or kemps. Brownness in the wool of any particular sheep is an indication of superior fineness (and such was the colour of the ancient fine-woolled sheep, and we need not look for the cause in any peculiar quality of soil or composition mixed with the wool); it will nevertheless scour white. But according to lord Somerville, this dark-brown tinge on the surface of the best fleeces amounts almost to a black, which is formed by dust adhering to the greasy yolk properties of its pile; and the contrast between it and the rich white colour within, as well as that rosy hue of the skin, peculiarly denoting high proof, surprize at first sight. The harder the fleece is, and the more it resists any outward pressure of the hand, the more close and fine will be the wool. Here and there a fine pile may be formed with an open fleece, though but rarely. And in Mr. Tollet's Spanish flock, purchased from lord Somerville, the average weight of each Spanish fleece in the grease was 5 lbs. 13 oz., and the lightest ewe fleece 3 lbs. 4 oz., and the heaviest ram fleece 11 lbs. 12 oz. of very good quality. This ram was not quite thirteen months old at shear-day, and was adjudged to weigh 20 lbs. *per* quarter. Mr. Tollet declined the price of two hundred guineas for him, likewise that of one hundred for the use of him during the tuppung season: he does not wash his Merino sheep before shearing, since, from the closeness of the fleece, it is not much liable to the intrusion of dirt: as it does not lose quite half its weight in scouring by the manufacturer, an estimate may be made after that rate of the value of the fleece in the yolk. The fleece of the young ram produced upwards of 35*s.* and the average produce of the whole unwashed Merino wool 18*s.* 9*d.* each fleece. The price of the superfine more than four-fifths of the whole, 6*s.* 3*d.* and 6*s.* *per* pound of the third sort, or *fribs*, which was but about one pound in the whole quantity. Mr. Bartley has somewhere mentioned, that four wethers of this breed produced the quantity of  $35\frac{3}{4}$  lbs. of wool; and of several ewes which produced 8 lbs. each, and of a wether which gave  $10\frac{1}{2}$  lbs.

In the introduction of this breed his majesty, as has been seen, has taken the lead, and from his flock a great number of the improvers of it have been supplied in the different

## SHEEP.

ferent sales that have been made since its first establishment. In the sale of 1803, in Kew Lane, under the direction of Sir Joseph Banks, the numbers sold, according to some, were twenty-four shearling rams, which produced the sum of 40*l.* 9*s.*; seven full-mouthed and four toothed rams, 17*l.* 13*s.* 6*d.*; fourteen ewes, 118*l.* 8*s.*; amounting in all for the forty-five sheep to 692*l.* 10*s.* 6*d.* The highest price of the shearling was 42 guineas, the lowest 6*l.* 7*s.* Of the full-mouthed rams, 28 guineas were the highest, and 7½ the lowest price. Of the ewes, 11 guineas the highest, 6 the lowest. The rams were put up at six guineas, the ewes at two guineas; the former prices at which they were allowed.

The wool has been sold this year uncoured at 4*s.* 6*d.* per pound. The size of the ewes somewhat under our pure Ryelands, but above several of our small breeds; heads sharp and well-shaped, with occasionally a black spot or two; wool externally having a dirty tinge, but without that red-brown hue which has been before mentioned; ears pendulous; perfect ewe-neck, with the sinking or cavity both before and behind the shoulder, the top of which is generally higher than the rump; capacious belly, the animal standing wide and well upon the legs; the rams generally of good size, some of them large enough for any purpose whatever, and of a great bone, but flat and symmetrical; several of them were of as good and useful form as need be seen, having compact loins and shoulders, and straight backs. Two or three individuals resembled very strikingly our Dorset and Hampshire flock; the characteristic velvet or silken gloss on the shorn faces of the rams was remarkable, and their countenance put one in mind of the fair-haired human complexion. Mouths by no means fine

And it has been observed, that the large tuft of wool covering the face of Merino sheep is extremely inconvenient in northern countries, where they have frequent heavy drifts of snow. And that it is Lord Somerville's practice to clip this and the leg-wool two or three times a-year, beginning about six weeks after shearing. But that in winter, and in very rigorous climates, it may not be proper to leave the head too bare and exposed, as it may produce disease. These clippings may be proper for inferior purposes, and the fleece be rendered more pure and valuable without them. The tuft on the head, and even the *throatiness*, or protuberance in the throat, characteristic of the Spanish sort, are, as it is asserted, discoverable, in degrees, in some of the native breeds, particularly the Ryeland, shewing its origin. And a good judge, Mr. Knight, contends, that the produce of a cross with this breed, and the *Archenfield* or true Ryeland sort, is extremely ugly, and, according to his information, subject to the foot-rot. On some rich pastures in Middlesex this has also been found to be the case in both the true and crossed breed.

*The Mugged Breed or Variety.*—This is a singular breed of sheep, which formerly prevailed throughout all the low lands of Northumberland. They had a short, coarse, curled wool, covering their heads, faces, and legs, and grew down to their feet; in form they resembled hill sheep; their shoulders low and sharp; sides flat; back rather arched; loins thin. It has been suggested, that this mugged appearance may have been the result of a Spanish cross. This sort of sheep has extended to Yorkshire; and traces of them are still visible, although they have long since given place to sheep of the long-woolled kinds. They are now chiefly met with in the northern counties.

*The Welsh Sheep or Variety.*—These, which are the most general breed in the hill districts, are small-horned, and all

over of a white colour. They are neat compact sheep. There is likewise a polled short-woolled sort of sheep in these parts of the country, which are esteemed by some. And the genuine Welsh mutton, from its smallness and delicate flavour, is commonly well-known, highly esteemed, and sold at a high price. But the fattening of the small Welsh sheep has not in general been found to answer in the southern districts of the kingdom. In short, this is a breed which stands in need of much improvement, and which is capable of admitting of it with much advantage to the sheep-farmers of that district.

The crosses of it should be with the larger finer woolled breeds, that afford good mutton, and be made with great care and attention. It is supposed by some, that the Welsh are the original of all the different breeds of sheep in the island.

*The Irish Breed or Variety.*—This is a breed of sheep, which is described in this way by Culley. These sheep are supported by very long, thick, crooked, grey legs; their heads long and ugly, with large flapping ears, grey faces, and eyes sunk; necks long, and set on below the shoulders; breasts narrow and short, hollow before and behind the shoulders; flat-sided, with high, narrow, herring-backs; hind-quarters drooping, and tail set low. In short, they are almost in every respect contrary to what he apprehends a well-formed sheep should be. The spirit of improvement in sheep-stock has however extended itself to Ireland, and there can be no doubt, therefore, but that they will soon improve this as well as other sorts of live-stock.

Indeed, since the period in which the above account of Irish sheep was given, many useful and important alterations and improvements have been produced by judicious selection and crossing in this sort of flock, in several different parts of that country.

However, independent of these numerous breeds or varieties of sheep, which are inhabitants of this island, there are in other countries many other kinds, which may be just noticed for the sake of curiosity, as they are occasionally seen in parks and pleasure-grounds in this intention. The more cold districts of Iceland and Russia afford a *many-horned breed* of sheep, mostly from four to seven or eight; having a coat of dark-brown coloured hairy wool, weighing about four pounds, and covering an interior one of short soft fur. Also in Russian Tartary, a large *lop-eared, polled* aquiline-nosed breed of sheep, somewhat resembling the Wiltshire and Dorset breeds in their shape, are produced, and which have a long thick wool, of a black and white mixed or roan colour, and in the place of a tail, a large cushion of fat occupying the rump; hence some naturalists have called them *fat-rumped* sheep. This and the broad-tailed breed are sometimes called the Kalmuc and Astrachan breeds. The projection of fat, in this, has an exquisite delicate marrowy taste. Some say the wool is rather short, not coarse, but having hair growing through it. They are said to be so prolific as to bring two or three young at once. And in Walachia, Crete, and through most of the Archipelago islands, there is a breed of sheep which have singular horns, twisted in a spiral or screw-like manner, standing in a perpendicular or diverging extending manner from the fore-part of the head, to some height. In size and shape tolerable, bearing a long shaggy but not coarse coat. Likewise in the extended districts of Persia, Syria, Egypt, and Barbary, the *broad-tailed* sheep are met with, the tail in some of which grows to the breadth of a foot, and to a length to bring them to the weight of from twenty to fifty pounds, on which account the shepherds are sometimes under the necessity of support-

## SHEEP.

ing them on a carriage to prevent them from galling and exhausting the animal. These appendages are mostly also esteemed a great delicacy, being of a nature between fat and marrow. Further, some of this breed of sheep, especially those of the mountainous parts, have a wool of extraordinary length and fineness, from which are made the expensive Indian shawls, and some other fabrics.

And the Guinea breed of sheep, said to be common in tropical climates, is large, strong, and swift, and though domesticated, are often found in a wild state; having coarse, hairy coats, short horns, pendulous ears, and a sort of dewlap under the chin.

What is called the *Madagascar breed of sheep*, is also of a good size, and well covered with a close pile of smooth glossy hair in the place of wool.

The *Buckharian breed of sheep* is also hairy, and kept in large flocks in Great Tartary. The island of Antigua has likewise a breed of the same kind. Sheep of this sort were imported from Spain by Sir Joseph Banks, with coats as sleek and smooth as those of a horse, and which never at any season exhibited the least appearance of wool or down, or any thing of a similar kind.

It may be noticed, that it has been well stated in a late practical work, that in the breeds of sheep there are evident differences in their sizes, forms, flesh, wool, and other properties, that admirably adapt them for different sorts of pastures, situations, and uses of the farmer. And that the large long-woolled breeds, from their being more slow, heavy, and tame in their dispositions than most other kinds, are in general the most proper for the rich inclosed pasture districts: the breeds which possess greater length in the legs, more activity in walking, and a less burthen of wool, are suited to the more elevated lands, such as the downs, moors, and heaths in different parts of the island, where the pasturage is less fertile and luxuriant; and that the small light carcassed hardy breeds are most adapted to the exposed mountainous situations, where the food is more sparing, and obtained with greater difficulty and expence. And in the Rural Economy of the Midland Counties, it has been observed that a very long-woolled breed of sheep, as the old Lincolnshire or Teeswater sort, is necessary also in the view of our finest worsted manufactures; and another, such as that of the *new Leicester*, for the inferior kind of grasslands, and the rich inclosed arable lands, where the folding system is not in use; for the supplying the materials of the coarser sorts of worsteds, stockings, baize, coarse cloths, blankets, carpets, and other articles of the same kind; while a middle-woolled breed, as the Wiltshire, the Norfolk, or the South Down, is wanted for the well-soiled arable lands, where the practice of the fold is in use, in the view of making cloths of the narrow medium kinds; a very fine-woolled breed, as the Herefordshire Ryeland, for the finest cloths; and the Shropshire, or some of the more hardy breeds, for the heathy mountainous situations. The Spanish and Cheviot sorts may also be proper in the last intentions. What is therefore chiefly necessary to be regarded in the introducing of new breeds of sheep, is to consider with attention the nature and situation of the pastures on which they are to be supported, and to carefully avoid making use of larger or finer breeds than can be properly sustained; as upon due management in this respect, much of the success in the improvement of sheep-stock must necessarily depend. Where bettering the form of the animal, and improving the quality of the wool or coat, are the principal objects, they may be effected by judicious crossing with proper breeds for the particular purpose, on the principles that

have been explained in speaking of the nature of breeding, and which is farther shewn below. (See BREED, BREEDING, and LIVE-Stock.) Indeed this last circumstance is one which should particularly engage the notice of the farmer in the business of stocking his lands with sheep, as it seems from numerous statements, that wool of the finest quality may be produced in this country by means of Spanish sheep, and their being properly crossed with our fine-woolled breeds, which is a matter of the greatest national importance, as affording a probable means of rendering us independent of the foreign supply of this expensive but indispensable article. The breeding sheep-farmer should therefore be particularly interested in promoting this sort of improvement, in all situations where the nature of his land will admit of it, which Lord Somerville has shewn may be the case in most instances where the short-woolled breeds of sheep can be properly kept, or probably on more than one-half of the pasture-lands of the island. And he has remarked that there is one inducement to this, which is that of its not interfering with the production of the most valuable sort of mutton, a point to which the sheep-breeders of this country have till lately been particularly attentive, almost without regarding the quality of the wool: as it has been found that the quality of the flesh in the different divisions of sheep inclines to the nature of the wool, the short-woolled sheep being close in the grain of their flesh, of course heavy in the scale, and in the taste high-flavoured; while the polled long-woolled sort are more open and loose in this respect, larger in size, and the mutton more coarse, and in general less saleable in the different markets in the kingdom.

In sheep there are certain good or bad qualities, properties, or dispositions which mark their value and importance in the view of the farmer, grazier, and breeder. That such certain peculiar properties and dispositions prevail, is well known to experienced persons of these descriptions, by sheep in exactly similar circumstances in every respect becoming more or less quickly in the state of fatness, &c.; as an improved disposition in them signifies an aptitude to convert their food or nourishment into flesh and fat. Thus, in a number of sheep of the same kind and age, under the very same management, when handled, a vast difference will be found in their condition and state of fatness, &c. Some will be in a state to go off many months before the others are ready, although put on the same land in equal flesh; and others, though kept far beyond the usual period of time, will never get into sufficient condition. The disposition of the former must, of course, be very beneficial and desirable to such sheep-farmers, as well as advantageous to the community, while that of the latter is quite the reverse. This is likewise the case in the breeding of ewes, as those which have it most are in the best state at the lambing time. But there are, it is supposed, some instances of exception in this and other descriptions of sheep, which possess good qualities, that have bad properties, which such sheep improves as the above should also be careful in detecting, otherwise they may be liable to sustain considerable injury and loss: and it is frequently seen on killing different kinds of sheep, that there is great difference in individuals of the same breed and variety.

There are several circumstances which are supposed to form or contribute to this goodness of disposition in these animals; they must be well bred, or come from such as have good properties; they must not be permitted ever to be in a state of want of food, or be reduced in flesh; they must have constantly good food in sufficient abundance, the richer, to some extent, the better; they must have their

## SHEEP.

frame or bone not too large for the quality of their keep; they must have a due relative proportion of parts; they must handle free and mellow in their flesh; they must have a peculiar appearance of countenance; and they must be perfectly tame and quiet. There are also other causes which in some measure conduce to this end, but they are of less certainty in their operation, such as the state and action of the blood in their systems, &c. The external forms and qualities of sheep which shew a good disposition are, a smallness of the head, a thinness and shortness of the neck, a deep wide breast, a wideness over the shoulders, a broad, straight and deep carcase or barrel, a smallness of bone and feet, the joints moderately short, the muscles or flesh plump and full, with a thinness about the insertion: the skin middlingly thin and mellow, of a fine texture, and a clear red and white colour; the wool of a yellowish-white appearance, a curly nature, and neither too long nor too short, but thickly set, the fat and flesh soft, with some sort of firmness in handling, and the countenance pleasant, and inclined to quietness.

The improved disposition or quality of sheep is promoted by taking them from poorer or inferior keep or soils, to such as are of a better and more rich kind, as in the case of feeds: but the removing of them from rich soils or keep, to such as are of a worse nature, has directly the contrary effect. The quality of the flesh, in one case, becomes soft and mellow, while in the other it gets more close and hard.

The nature and quality of the land or soil, when any breed of sheep are kept upon it for a length of time, will, it is believed, throw out the suitable size for it, and certain accidental qualities will occur according to its sort, which, when properly managed by the breeder, will afford an improved disposition in the animals. In such a case improvements may have a probability of being produced, by having the male smaller in size than the female, and by changing him from too good or rich keep, so that his constitution may be in some measure delicate, by the female having her nourishment regular, and so as at no time to be lowered in flesh; and when a more full supply of food may be wanted, by the increase being moderate. So as to preserve rich keep for the young, in its advancing growth; by breeding from such sheep as are the most kindly, shew the best disposition, and allow the fullest profit, on the particular soil or land on which they are bred and pastured; by choosing and selecting the middle-sized sheep of the flock to breed from, and not the largest, as it is favourable to be rather under than over the quality of the soil or land for forming good disposition; by refraining to breed from sheep displaying a bad disposition, or which have defects; and by cautiously using for this purpose ewes which have had lambs, and are not too old, as disposition is supposed more likely to be produced from the second than the first lamb: and lastly, by the mode of breeding that is called *in* and *in*, or in the same line, which greatly contributes to form disposition.

In the degenerated form of sheep, the reverse of all this will, of course, mostly take place; they will have these qualities or properties in a larger or smaller degree; their heads will be generally short and thick, though occasionally rather long, and of a coarse nature; the neck, for the most part, long, thick, and concave in the higher part; the carcase long and thin, and the ribs flat, usually termed "flat-sided," while in improved sheep they bow out almost at right angles with the spine, in somewhat the barrel manner. Narrow shoulders, the loin not wide, the back not straight, and the belly gutty; the breast or chest contracted, without being deeply let down; the legs long, and thigh

not full or fleshy; the flesh thin, of a close texture, and thick about the insertion of the muscular parts; the feet large and coarse; the flesh hard in handling, or what is sometimes denominated "sticky;" the countenance far from pleasant, and the nature wild; the wool coarse and hempy; but capable of improvement by attention; difficult, or requiring time in fattening; the mutton often of good quality for eating, of a firm grain, sweet flavour, and abounding in gravy.

Sheep of this kind in general require a much greater quantity of food for their growth and support, and for fattening, than the improved sort, which is a circumstance that must evidently be disadvantageous to the breeder, grazier, and the whole community,

All such persons as are in the habit of breeding and fattening sheep, and have sufficient experience, find that they depend on the qualities or properties of their breeds for growth and improvement: some will not fatten at all, or be as long again in fattening as others, and this most commonly occurs in such as are not of the individual's own particular breed or kind. The degeneracy of sheep is readily seen and easily proved in the management of them. And some consider almost the whole of the breeds or varieties of this country to be more or less in this state, or that there is not probably more than one which can be said to be truly in an improved condition, on the exact principles of improved forms.

This degeneracy is in a great measure the consequence of neglect or error in the breeders and managers of sheep, as when they thrive and fatten well, that is to be attributed to proper selection, suitable keep, and a due regard to the true and exact principles of management: but when, on the contrary, they do not go on to fatten well, but decline into a state of degeneracy, it proceeds from neglect, starvation, and the want of such true principles in their regulation and management. As though a lamb may possess good proportions, yet from neglect and other causes, it may be reduced to a state of poverty; which, when it takes place, its degeneracy may be dated from that period, as its constitution is injured, and an unfavourable action is given to the system. The longer it is kept in this state, and the more frequent the changes it may undergo, the more conspicuous will its degeneracy be. Nature, then, it is supposed, will throw out indications in conformity to this decline; the head will increase in size in a greater proportion than the other parts. The body will become thin and long; the bones will be irregular in their growth; and there will be a want of symmetry in the whole system. The causes which are the foundation of such degeneracy are believed to be these; the rams being too large in size, and kept in too high a manner; these and the ewes not being well adapted to the soil, but too large; the lambs being kept in an occasional state of want or starvation; the neglect in not breeding a proper number for the purpose of selection; the ignorance of breeders in regard to the true principles, in respect to the forms of sheep or their management; the frequent crossings of varieties of the same breed; the presence of dry summers and hard winters, which tend to incline the constitution to an unfavourable action, and consequent degeneracy; and the want of good water, which is very prejudicial to sheep.

It is suggested, that it is to be lamented, that almost all the breeds, in every situation, are found to have one or other of the bad properties or qualities already noticed. However, of all sheep, the shape or form of that of the Indian sort is probably the worst which is produced; and the Wiltshire, the Welsh, and many other breeds, are not without partaking of too many of the properties and imperfections of the same kind, in addition

to their other defects. It is to be hoped, however, that a more active exertion, and investigation of the matter, in sheep-farmers, will in a short time be productive of the requisite improvement in this sort of live-stock, and that by having recourse to superior modes of breeding, rearing, and management, an equal pace will be kept in their advancement with that of any other branch of the farmer's art.

It may be noticed, notwithstanding what has been already said, that it is stated to be almost universally and unanimously the practice of the breeders on the South Down hills, to exchange the rams every third, fourth, or fifth year, as it is conceived essentially necessary to the preservation of the health, the size, and the bone of the flocks, though quite contrary to the maxims laid down by some eminent sheep-farmers, who are strenuous promoters of the method of breeding *in* and *in*, or in the same line, continually, when there is a good breed or sort of sheep. Flocks that are stated to have been nearly ruined in constitution and habit by this means, are said to have had a wonderful improvement by the change of the rams. See BREEDING.

The question concerning the best and most profitable size of sheep for the purpose of the grazing farmer, and for producing the largest acreable quantity of food and other products for the use of the community, is a matter of very great interest and importance. Though it cannot probably be disputed but that different sized animals of this sort must be had recourse to for different situations, sorts, and qualities of land, &c. yet the considerate sheep-farmer will, perhaps, mostly perceive the propriety of having his ground stocked with not too large a sort of sheep. It will most likely be the best way for such farmers to fully consult the nature and properties of the soils of their pasture or other lands, previously to their fixing upon the size of their sheep-stock which will be the most suitable and advantageous for them, as where their pasture or other grounds are inferior in their nature and richness, the size, of the live-stock of this sort, which is admitted, cannot with propriety be so large as in the contrary circumstances, even where light stocking is practiced, for hard and pinching seasons will reduce the stock to the quality of the land. Though many are advocates for very large-sized sheep, probably from want of sufficiently considering the nature of the subject, it is never found that those who stock with such sized animals, ever produce so much mutton on the acre, or gain so great a profit on it, as those who make use of a middling-sized stock. Some indeed think that four small-sized sheep may be kept on the same extent of land which is required for three large ones; and that in some cases, allowing the sheep to be equal in disposition, the same number of small ones, of about nine stone each, may be fattened on the land that will barely be sufficient to feed three of from ten to eleven stones. Small-sized sheep-stock have also many other advantages attending them. Many make complaints against sheep with improved forms, such as the new Leicester, as being too small, from the mistaken idea of their close form, as although they may be short and compact, there is a greater width and depth of carcass in them; by which they do not come much, if any thing, short of the weight of the more apparently large breeds.

It is unquestionably a great error and defect in the sheep-grazing practice to choose sheep of too large a size for the constitution of the soil, and the quality of the keep which it affords. The nature of keep will indeed itself be the cause of different sizes in sheep-stock, if they be steadily maintained on the same sort of land for some length of time, and this in some measure has produced the differences of size in the different breeds of this animal.

The particular advantages of the different sizes of sheep

may be summed up somewhat in this way. Those of the large sort are supposed capable of being kept in equal proportion, on the same quantity of land, and of bringing more money at the market, than the smaller breeds; they are likewise conceived to fatten in a more kind manner. If the list of these conclusions were true, they would certainly have a decided superiority, but the result of well-made trials, with equal proportions on the same pastures, shew the contrary to be the case. And in regard to the latter, it has probably proceeded from its being noticed that the largest sheep are mostly the strongest and best shaped, without considering that they are always below the quality or constitution of the soil or land on which they are fed or fattened; hence it is by no means in favour of large sheep on all kinds of land. And though it is somewhat generally allowed, that two small sheep of the same breed will equal in weight one large one, yet the latter will have less offal in proportion than they, which is certainly a desirable property in large flock of this kind.

Small sheep-stock are however more active, and feed closer than large, as well as on food which is of an inferior quality; they are capable of being stocked in the proportion of three to two on the land; they will produce more meat on the acre, and be more hardy than large breeds; they injure pastures less than large sorts; they will, where the proportions are the same in relation to the sizes, soonest become fat in the smallest, in any two sheep. This may probably be concluded as always the case, where the regularity of form and proportions are equally good and exact: as small sheep reach the state of maturity sooner than large ones, the smaller breeds are ready for sale five, six, or more months before the large, which is beneficial in every way: the smaller breeds of sheep are almost constantly preferred by the butchers, as the mutton is more suitable, saleable, and desirable at particular seasons, and as having two fifth quarters instead of one, where the weights are equal. It may, therefore, upon the whole, be considered as the interest and advantage of grazing farmers in general to breed, rear, and fatten sheep which are of the middling size, however they may have hitherto been led away by other circumstances, such as great size, extreme fatness, &c. without sufficiently taking into the account the expence at which they are produced.

What regards the *proof* of sheep is more the interest of the butcher than the grazing farmer; but it has much to do with the difference of breed, as all the more thin-fleshed breeds of sheep, as the South Down, the Norfolk, the Welsh, and several others, mostly die well for the advantage of the butcher, while those of the fleshy sort, which have improved dispositions, such as the new Leicester, &c. commonly die to his disadvantage; so that where the great object is proof, such breeds must be chosen as approach the most to the former. It is not, however, probably the breed simply, but the form of the sheep that gives the proof. But as such sheep as afford great proof mostly require a longer time in fattening, the grazing farmer should be careful not to breed or purchase such sheep as are so formed as to convert their food into tallow, in the place of enlarging the size of their muscular parts, and producing meat of a sufficiently fat quality.

The age of sheep has also much to do in the proof which is afforded by them, as the older they are, in general, the better they die in this particular, as their full growth allows the nourishment to go for fat or tallow, according to the nature of the sheep, as where the form is inclined to be bad there will be more tallow, but where the disposition has a tendency to be good, more fat produced on the outside. Keep has likewise some influence on proof as the best pastures, and such

## SHEEP.

as are the closest stocked, are found in common to afford sheep that give the best proof, but it has probably less effect in this way than is generally imagined, as particular breeds give a superiority of proof on poor lands, to that of others on very rich. Time has considerable effect in giving proof to sheep, as by it fat is enabled to be collected and formed internally; but disposing of the animals at short periods constitutes the great advantage of the grazing farmer, and he has no reason to breed and fatten his stock for the benefit of the butcher and other dealers in tallow. The management in regard to breeding and crossing, as well as the nature of the wool, are said to influence the proof in these animals, as where the more ordinary forms are adhered to, the proof will be greater than in the contrary circumstances, as they have a greater tendency to form tallow and loose inside fat. And though some think long white watery wool favourable to proof, others suppose it the contrary, as denoting a disposition to fatten quickly, and as preventing inside fat by taking away the nourishment, thereby concluding fine short-woolled sheep more disposed to afford good proof. The good or bad forms and feel of particular parts, as of the head, the neck, the breast, the back, the barrel, the bone, the skin or pelt, and the flesh, often afford indications of proof, though not always such as are certain; as when the first is large, the second long and thin, the third narrow, thin, and high, the back thin and straight, the carcase thin and not well rounded, the bone long and large, the hide or skin sticky and hard, and the flesh harsh. But these different indications of proof cannot, it is evident, always be wholly depended on, as sheep may have one or more of the marks or properties which denote good proof, but which may be counteracted by others that favour disposition and other similar qualities to the contrary; consequently where two sheep are similarly formed, that which has the largest head and firmest flesh may mostly be concluded to give the best proof. The opinions on proof ought, in fact, constantly to be formed from the greatest combination of the marks of it met with in the particular animals examined.

Perhaps, so far as proof is capable of being judged of before the animals are killed, it may be known by the feel of the fat glandular part, which extends from the bottom part of the neck to the shoulder, which in lean sheep is so very small as scarcely to be felt, while in those that are properly fattened by sufficient time, or *soaked*, as it is sometimes termed, there is a different sized cushion or projection of the same fat glandular part extending to the thick portion of the shoulder; by the feel on the ribs and tail or dock, which, when it is thick, fat, and mellow, the sheep will commonly, it is thought, die well for proof. A thick loin is sometimes also thought a mark of proof in the kidney and weight. The feel of the fore dug of barren ewes and the cod of wethers, likewise shew, it is thought, proof. Many of these marks must, however, be allowed to be precarious and uncertain.

It cannot on the whole be doubted, from what has been stated on the subject of proof, but that the interests of the butcher and the grazing farmer are at variance as matters stand at present, as what is the gain of one must be the loss of the other, where the thing is well understood.

In the Agricultural Survey of the County of Norfolk, lately published, it is noticed, that the South Down breed is getting rapidly into the possession of all the country from Swaffham to Holkham; but that from Brandon to Swaffham many Norfolks remain. However, some mixture was observed even in that district. And it is stated that Mr. Coke is well satisfied of the advantage of the breed from Leicester

ewes and Bakewell tups. His flock of 160 new Leicester ewes produced, in 1802, 100 lambs; his flock of 630 South Downs produced 830 lambs living in June. The same farm, it is added, yields a most interesting comparison between Norfolks and South Downs; his former flock was 800 Norfolks, *SELLING all the produce*: he planted 700 acres, and now has 800 South Downs, *KEEPING all the produce*. Further, that his new Leicester hogs and theaves produced 8lbs. of wool each in the same year, yet they had been hard kept on feeds fed very bare. And it is stated, that though he had a high opinion formerly of the cross between the new Leicester tup and Norfolk ewe, now (1803) his opinion is changed from much experience; so that he prefers the cross of a South Down ram on a Norfolk ewe to that of a Leicester ram. And it is added, that Mr. Hoite has had the same cross, and they come to 32lbs. a quarter, at two-shear. He put a Norfolk tup and a Bakewell tup at the same time to the same parcel of Norfolk ewes, and at St. Ives fair sold the lambs fat at six or seven months old, and the Bakewells brought just double the price of the Norfolks. In April 1799, Mr. Coke, on sending Norfolk, South Down, and new Leicester three-shear wethers to Smithfield, that had been fed together, the return was:

	£	s.	d.
Average per head, Norfolks	-	-	3 0 0
Leicesters	-	-	4 2 2
South Downs	-	-	3 7 2
Ditto, fleeces included, the others being in their coats	-	-	} 3 15 2

And in May following above 100 going, the South Downs beat the new Leicesters by 2s. a-head. It is also observed, that at Waterden, Mr. Money Hill, with about 500 acres less land than at present, kept 27 score breeding Norfolk ewes, and sold the produce of lambs; now he has 35 score South Down ewes, and keeps their produce, selling his wool at 5s. a tod more than the Norfolk. And further, that Mr. Bevan, in 1792, had a South Down flock, of 30 score, on one farm, and having a flock of Norfolks on an adjoining farm at Knattishall, he had an opportunity of comparing the wool exactly: 34 score of Norfolks produced 43 tod at 28lbs.; and 34 score of South Downs produced 61 tod; which 61, kept till November, became 64, but the summer very wet.

	lbs.
South Downs	1708
Norfolks	1204
Superiority, just $\frac{3}{4}$ lb. each	504

Also that in 1791, the shepherd would not let his own Norfolk ewes take the South Down ram; but in 1792 he was ready enough. He said they would eat harder than the Norfolks; and would eat what the Norfolks would not; that they are more quiet and obedient than the Norfolks; so that he has done with them what he could not do with the Norfolks; folded them almost to an inch without hurdles. And that a neighbouring farmer bought three rams of Mr. Bevan, at 5l. 5s. each; but afterwards repenting, because they would *shave* his flock, Mr. Bevan offered him 6d. a-head, for all their lambs, more than he sold his Norfolks for, in the same flock, at Ipswich fair. The offer was accepted; the price proved 6s. 3d. for the ewe lambs, and 9s. for the wethers. Mr. Bevan resold the ewes for 9s. and the wethers for 10s. 6d., or 2s. 1 $\frac{1}{2}$ d. a-head in favour of the half-breds. Further, that when his sheep were Norfolks, he kept 500; but in 1794, he had 960 South Downs. That the produce

## SHEEP.

duce of 116 ewe lambs, bred by Mr. Bevan at Riddlesworth, 1792, was:

	£	s.	d.
Wool, 12 tod 16lbs. -	26	8	0

Actual profit -			

Farther, it is also added, that he was early in trying South Down sheep, but finding them tender at lambing, went into a new Leicester cross; these he abandoned, and got back to the South Downs, but still esteems them a tender breed, and that they ought to have yards sheltered and littered for lambing in bad weather; remarking, that all the farmers he knows on the South Downs have these yards for that purpose. It is likewise stated, that Mr. Bircham, at Hackford, declares against having any favourites; he has generally bought Norfolks, and half-bred lambs; some few South Downs, but they did not answer: has had some Leicesters; any sort he can get worth his money. Little farmers, who keep a few sheep, find the polled breeds very convenient from their quietness, and therefore prefer them. Norfolk lambs bred near Cromer, bought by Mr. G. Jones at 14s., were run on stubbles in the autumn, and put to turnips at Christmas, then to layers of the first year, probably as the best food for sheep, and fold shearling wethers at Michaelmas at 55s. each; 20lbs. to 24lbs. a quarter. And colonel Butler, at Haydon, is said to be convinced that Norfolks answer better than South Downs: shearlings sometimes affording 20lbs. and 25lbs. a quarter, and 19½lbs. of tallow; he has a breeding flock of 400, and fold his wether lambs at 26s. and his ewe lambs at 24s. Mr. Johnson, of Thurning, has 40 score of South Downs, which he has been rearing these six years, having bought many ewes, and got good tups. He has, however, a good opinion of Norfolks, and will not be surpris'd to see them come into fashion again. In May 1792, he sold two-shear Norfolks at Smithfield for 3l. each. He admits their rambling disposition, which is much against them; and he is clear that he cannot keep so many on his farm as of South Downs. The South Down wool is not, on good keep, so good as Norfolk wool, but the fleece is heavier. Five years ago he got a lot of Yorkshires from the Wolds, white faces, polled, and the wool very coarse, but they thrive wonderfully; never having had any sheep that did better, inasmuch, that he was sorry when he parted with them. Norfolks, he thinks, will bear folding better than South Downs. The latter will, however, come to hand rather sooner, but not on ling: has had three-shear South Downs of 28lbs. a quarter. Also at Snettisham, Mr. Styleman, the writer asserts, keeps 2000 of various breeds, South Downs, new Leicesters, and half and half; in number considerably more than when, on the same land, he kept Norfolks: his farm may, and probably does, produce more sheep-food than it did at that time; but he is perfectly clear in the great superiority of the number; this circumstance deducted, and that the profit is considerably

greater; and he is clear also in the superior hardiness and kindness of feeding of the new breeds. Of all cross-breeds, he thinks the first cross of the Leicester tup on the Norfolk ewe the best, and that wool now (1802) sells at 46s. a tod; fleeces 4lbs. And at Hillingdon, all are either Norfolks or half-breeds, a Leicester tup on a Norfolk ewe. Captain Beacher thinks there are no sheep in the island which the Leicester will not improve. He has grazed many Wiltshires, and thinks them the best of all for cole-grazing in the fens. But Mr. Beck, of Castle Rising, has had South Downs thirteen years, beginning with some from Mr. Tyrel's, of Lamport, and has imported three or four times since. He has now 800, and is quite convinced of their superiority to Norfolks; when he was in that breed, he had not half the number; but after abating fully for improved husbandry, and every other circumstance, he is clear that there is a superiority of four to three. His fences are and must be bad, and in such a farm quietness is a vast object: his farm 486 acres. He gained the first prize for ewes, both the last and this year at Swaffham, and also at Holkham. The surveyor examined his flock attentively, and it certainly is a very beautiful one. His wool now averages eight to a tod, equally of hogs and ewes: his Norfolks totted twelve: he is clear that, take the country through, they average half as much again as Norfolks. Before he took the farm there were fifty sheep on it, and a dairy of cows. What an improvement! However, in the vicinity of Downham are found all sorts of breeds: towards the river, Lincolns and Leicesters; higher up, Norfolks and South Downs. Mr. Saffory likes the South Downs best, but thinks that if as much care and attention had been exerted to improve the breed of Norfolks as the South Downs have experienced, they would by this time have been a very different sheep. Norfolk three-shear wethers fold in April last at St. Ives, at from 4l. 4s. to 4l. 10s. each. At Bretenham, Mr. Twiss keeps 68 score of breeding Norfolk ewes on 1800 acres of poor land. He had a South Down tup some years ago from Mr. Crow, but he could not perceive that the breed did better than Norfolks, though they stood the fold to the full as well.

In the district called Marshland, Mr. Dennis, of Wigenhall, St. Mary, grazes only the best Lincoln wethers; he buys from May-day to Midsummer; keeps them over-year, clipping twice, average price 50s. to 60s. and sells at 65s. to 75s. getting 18lbs. in the two fleeces: his good land will carry six *per* acre, on an average, in summer; in winter, two on three acres; and these will quite preserve their flesh; if the season be favourable, will get something: he thinks that there is no other breed so profitable here; even a strain of the new Leicester is hurtful, as they will not stand the winter so well. Sheep the chief flock, though some Lincoln bullocks. He never gives hay to sheep, nothing but grafs; 32lbs. a quarter his average of fat wethers. But Mr. Swayne, of Walpole, prefers the cross between Lincoln and Leicester: he buys them shearling-wethers, about Lady-day; fall year 3l. to 3l. 10s. each, but has had them at 36s. and 38s. He clips the best twice, three to a tod, which he likes better than heavier fleeces of sheep demanding more food. Some give 17lbs. or 18lbs. of wool. At Michaelmas he culls the worst, or buys cole for them, if reasonable; sells all by Midsummer, making 8s. or 10s. a-head, when bought in high, besides the wool. Very few beards are kept.

Also in Hertfordshire, some prefer the South Downs to Wiltshires, as the latter have the goggles often, but the South Downs never. But the long-legged Wiltshires suffer less in folding on wet land. But in other places the result of the comparison seems to be, that South Downs do better on

## SHEEP.

grafs-land than Wiltshires, and will in that case thrive more, and better support the hardships of short food; but on arable land with plenty of turnips, clover, rye, tares, &c. in ample provision, the Wiltshires are more profitable than the South Downs. The Wiltshires are large sheep, and consequently require to be well kept. In the trials of Mr. Hale, of King's Waldon, for five or six years, nothing beats South Downs, where there is much grafs; but on artificial grafs and turnips, without a breadth of natural grafs, they will not do like the Wiltshires; for which reason Mr. Roberts, on his own farm, keeps Wiltshire ewes, and crosses them with South Down rams: so that they lamb in March. When put to grafs they are folded, and some lambs are fold at 34s. in the beginning of harvest; some twins at 31s. 6d.; and the best are kept. He approves so much of them, that he intends to continue them. Mr. Hale's flock is a capital one, and the wool remarkably fine. And between thirty and forty years since, Mr. Calvert of Albury had Lincoln sheep, but fold them, from conviction that they did not answer: he was then, for about twenty years, in the Wiltshire breed; and lastly, he changed these for the South Downs, which he has had for the last seven or eight years, and prefers them to all. He has no other but lord Pelham's breed, both lambs and ewes, and considers the more modern attempts to raise a *finer* race, as likely to prove mischievous: he will not have any thing to do with them. His six-toothed wethers weigh eleven stone and a half. He finds the breed extremely healthy: they very rarely die; and are subject to much fewer dilempers than the Wiltshires. And Mr. Smith has changed Wiltshires for South Downs. He has about 400 in all, some of them Wiltshires; they are *fed and worked together*, and folded on wet lands. The South Downs in exceeding good order, but the Wiltshires very inferior. But about Barkway, South Downs are not yet introduced; Mr. Whittle, however, gave it as his decided opinion, that *fed and work* Wiltshires and South Downs together in the same manner, and the former will prove to be the most profitable; the latter are much injured by the dirt, as they are too short in hair and legs; it was tried at Kimpton Hoo, and such was the result. He has fold Wiltshire wethers thrice shorn, at 7l. 14s. each. And Mr. Doe, of Bygrave, keeps Wiltshire ewes, which he crosses every year by new Leicester rams; but goes no farther than the first cross. These answer greatly, whether the sale be fat lambs or shearlings. He does not approve of South Downs, on account of their inferior weight.

However, from the high character which South Down sheep have lately attained, it may not be uninteresting to give Mr. Young's account of their first introduction into Norfolk. Heremarks, that when once an improvement has spread so much as to become an object of importance, there are generally many claimants for the merit; and if such claimants are only heard of many years after, but little attention is due to them. With regard to the neighbouring county of Suffolk, he can speak with some accuracy, but should not mention it on this occasion, were not the fact connected with the introduction into Norfolk. In May, 1785, he published an account of an observation he had made in 1784, the year he brought them into Suffolk from Suffex; and it being printed at the time, the fact will admit of no doubt. He recommended them strongly to every gentleman and farmer he conversed with on the subject; and at his persuasion, as many well know, the late Mr. Macro, of Barrow, purchased that flock which the earl of Orford, after his death, bought and established at Houghton. Mr. Macro died in 1789. And in a paper printed in the Annals, in 1790, he (Mr. Young) remarks, "I have had six and twenty

years' experience in Norfolk sheep, and once thought so well of them, as to carry them into Hertfordshire; but in the advance of my practice, I began gradually to doubt the superior merit of that breed. I thought that of all the sheep which I had examined particularly, none promised to answer so well for the general purpose of the counties of Norfolk and Suffolk as the South Downs. I began the import in 1784, and in 1790 had 350. I had too much friendship for the late Mr. Macro, to advise him to try any experiment that I was not clear would answer to him. I repeatedly urged him to try the South Downs; he listened to me with attention for some time, but would not determine, till having seen the number I kept proportionably to the quantity of land, and at the same time with some Norfolks, it proved to him that the South Downs were worth attending to; and the journey I persuaded him to take into Suffex, giving him an opportunity to converse with various noted sheep-masters there, he determined to make the experiment: he went over, previous to Lewis fair, and bought a flock of them. The lambs fold well at Ipswich fair. Mr. Le Blanc, at Cavenham, also turned South Down rams to 700 Norfolk ewes: he found no difficulty at Ipswich; and his shepherd, after three years' obstinate preference to Norfolks, gave up his old friends, and actually set South Downs for his shepherd's stock. Whether the breed should or should not, in the long run, establish itself, I have the satisfaction of feeling that I have done no ill office to my brother farmers by introducing it. From the daily accounts I receive, I have good reason to believe that it will be established."

The farmers in Oxfordshire employ many different sorts of sheep, as the Wiltshire, Berkshire, and some others; but the South Down and new Leicester, and their crosses, are fast driving the other sorts out of the county, as being more profitable in the number that can be kept on the same extent of land, in fattening more expeditiously, and at earlier periods of their growth, in folding equally well, and in the value of their wool. Some, however, think, that the long-woolled sheep are very profitable on farms of the stone-brash kind, and have large flocks of that sort. In this district, in general, the quantity of sheep that is kept is large, in proportion to that of the extent of the farms.

In Berkshire, the large Wiltshires and the breed of the county are giving way to the South Down, and other small-sized breeds, as yielding more profit, fattening quicker, and doing better in general. The new Leicester, so far as they have been tried in proper situations, have also answered well. Some crosses of these smaller breeds have likewise been employed with considerable success.

In the county of Essex, several sorts of sheep-stock are made use of by the farmers, as the Norfolks, Wiltshires, Lincolns, new Leicesters, South Downs, and different crossed kinds; but the superiority and advantage of the Downs are now almost every where admitted. The Dishley or new Leicester sort is also held in much estimation in many places, especially where the soil is of a dry light nature; as the wether lambs of this breed, and that of the Downs, on being constantly kept together on the same land, until they became fat, the former were invariably drawn off the first, and were the fattest and heaviest. Besides, rams of this sort are preferred for being put to Norfolk ewes, to those of the other breed; as the produce is larger, and sooner fat. The new Leicesters are by some, however, thought inferior to the South Downs, as being such bad breeders; one hundred of them only producing eighty lambs, while the same number of the Downs will bring one hundred and twenty.

## SHEEP.

In the district of Devonshire, many kinds of sheep, besides the native breeds, are had recourse to by the farmers, as the Dorset, new Leicester, Cotswold, and South Down, with crosses of these and several other kinds, as may be seen by the table introduced above. The last of these breeds seems to be fast making its way, in some places where the land is dry, in this county too; but other sorts and crosses are held in great favour for different purposes and uses, as for mutton, wool, feeding, and different others.

In many of the northern and other counties, as in Yorkshire, Lancashire, Cumberland, and several others, the new Leicester, South Down, and different improved breeds, are now beginning to be had recourse to, and supplanting the old native or other kinds.

The trials have hitherto been so few, in regard to the comparative advantages of different breeds of sheep, in what regards the relative proportion of food to mutton, offal, tallow, live and dead weight, and many other points, that the stock-farmer has been kept much in the dark. In order, however, to fully clear up and ascertain these essentially important matters, so absolutely necessary to the perfect knowledge of the subject, the earl of Egremont lately ordered the following experiment to be made. The wether lambs of the preceding spring were ordered to be put up by themselves, into a paddock adjoining the Home-park. There were of

South Down wether lambs	29—12 best saved for rams.	
New Leicester do.	25—6 do. saved for do.	
Half-bred new Leicester and South Down wether lambs, from same get as above	—	12 18
Romney-Marsh wether lambs, out of Mr. Wall's ewes by his own ram, which, from the custom there, of not having artificial food, were not lambed till May, being therefore nearly two months younger than any of the rest	—	7
Deduct rams	73 18	55

These fifty-five wether lambs, put into the paddock in the month of August, were brought up and examined on the 25th of the June following, when it was found that twelve of the South Down, and all the half-bred South Down and new Leicesters, were in a marketable condition; but that none of the true new Leicester or Romney-Marshes were in any proper state for sale.

	£	s.	d.
Of the South Downs, ten out of the twelve were sent off to Smithfield market, some days afterwards, and fetched <i>per</i> sheep	1	14	0
Of the half-bred new Leicesters and South Downs, ten of the twelve, sent a week before to the same market, brought <i>per</i> sheep	1	13	0

It is remarked, that the half-breds were seemingly the better sheep; but they went to a bad market, when the prices were low.

The two of the half-bred sort that remained, and which were in eqal condition for the market, were kept back, as forming part of the trial, detailed next column.

Here, however, it is necessary to pause, it is said, as the experiment is already decisive of one point, namely, that at this age of six months, as noticed above, those two breeds were so much more advanced than the others, that they might be profitably cleared from the land, and a fresh flock sent in. It will remain, it is said, for the future progress of the trial, to ascertain whether such fresh flock would not pay better, than continuing the old; and for this purpose it may be calculated, that the sheep now sold at the above market at 3*s.*, with the addition of 3*s.* for wool, pay for sixty-four weeks 7*d.* the pound from the time of their being lambed. This is noticed to be a very considerable profit; and that if it should turn out, that keeping them much longer is not attended with an advantage somewhat proportionate, it will clearly prove the superior benefit of that breed, which may be got rid of at so early an age. And it is thought worthy of remark, that not one of the true new Leicesters being in any condition fit to be drawn off in the first lot for market, is a circumstance most strangely contradictory of assertions without end, that fattening at an early age is almost peculiarly a characteristic of that breed.

But to proceed with the trial.

	Weighed	Ten Weeks' gain.	Gain per 100 lbs.
	lbs.	lbs.	lbs.
Sept. 7. South Downs	273	33	13
Leicesters	258	46	21
Half-breds	294	34	13
Romney-Marshes	270	34	14

It is noticed, that this result is not very different from what might have been expected; for as the Romney-Marshes and new Leicesters were very much behind the South Downs and half-breds ten weeks before, it was natural to suppose, that when they did begin to thrive, they would do it in a more rapid manner.

	Weighed	Loss in 12 Weeks.	Loss per 100lbs.
	lbs.	lbs.	lbs. oz.
Dec. 1. South Downs	264	9	3 0
Leicesters	251	7	2 0
Half-breds	282	12	4 0
Romney-Marshes	269	1	0 6

It is considered as very material, in all trials of this nature, to note the losses, as making such attempts double, by not only shewing when the sheep thrive, and which do best, but equally by marking when they go backward, and which breed is most capable of withstanding those circumstances which operate against them all. In the above scale, the difference is not very material. In that lot which did the worst, the loss, it is said, amounts to about 1*d.* *per* week; but that it is unfavourable to every lot, that in a period including the best part of the autumn, as sheep should thrive, when the weather is suitable, deep into the month of November, none of them should have gained, which they ought to have done considerably. Their pasture, however, though good in quality, was bare.

The result being found, the sheep were ordered to be starved for twenty-four hours; and after which, to be turned out for other twenty-four hours; proposing, by thus weighing them, to ascertain the quantity of food eaten, and the quantity voided: it being rightly conceived, that if, upon the repetition of such trials, there existed any remarkable superiority, or any material difference, between the respective breeds, it might throw some light upon the general inquiry.

South

# SHEEP.

	Loss by Starving.		Loss per 100 lbs.	
	lbs.	lbs. oz.	lbs.	oz.
South Downs	8	3 0		
Leicesters	11	4 0		
Half-breds	17	4 6		
Romney-Marshes	5	0 14		

The sheep were then turned out, and twice weighed, after twenty-four hours eating each time.

	Gain in the	Gain in the	Total.	Gain
	1st 24 Hours.	2d 24 Hours.		per 100 lbs.
	lbs.	lbs.	lbs.	lbs. oz.
South Downs	1	6	7	2 10
Leicesters	6	6	12	4 13
Half-breds	10	9	19	6 12
Romney-Marshes	0	5	5	1 13

The result of these weighings shew that the half-breds lost most, and gained most; that the Romney-Marshes lost least, and ate least; that the Leicesters lost more than the South Downs, and ate more. It is suggested, that such trials must be repeated many times, before conclusions can be fairly drawn. How the Romney-Marshes, in the first twenty-four hours, could gain nothing, is not to be accounted for, as the weighing was performed with accuracy.

Weighed again in the succeeding month of March, in the next year, which, as it will mark the loss sustained by the severest part of the winter season, deserves particular attention. They were at grass the whole of the time.

	Weighted	Loss in 4 Months.	Loss per 100 lbs.
	lbs.	lbs.	lbs.
South Downs	253	11	4
Leicesters	214	37	14
Half-breds	253	29	10
Romney-Marshes	254	15	5

The result here shews that the Leicesters, which is remarkable, suffered the most; from which it is thought, that it may fairly be concluded, so far as one trial goes, that the great peculiarity of that breed is not by any means what has been contended for, a capability of supporting itself on little food; but that, on the contrary, it demands a very plentiful nourishment, and will bear the want of it worse than any of the other breeds.

The half-breds are the next in the order of demerit: the South Downs are the best of all.

	Weighted	Gain in	Gain
		12 Weeks.	per 100 lbs.
	lbs.	lbs.	lbs.
June 19. South Downs	299	46	18
Leicesters	275	61	28
Half-breds	310	57	22
Romney-Marshes	317	63	24

The period from the 30th of March to the 19th of June necessarily forms another interesting portion of the trial. as it takes in the whole flush of the spring growth of grass. Here the result, it is said, is also remarkable, and strongly in confirmation of the preceding observations on the Leicesters; for when in favourable circumstances in regard to food, as in the present case, from season, they exceed all the rest. The Romney-Marshes, however, approach near to them; and as these had lost, in pinching circumstances, much less, their superiority upon these two weighings seems to be clearly ascertained; and which will appear the plainer, by comparing the weight of December 1st with that of June 19th.

	Dec. 1st.		June 19th.		Gain.	Gain per 100 lbs.
	Weights.					
	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.

Leicesters	251	275	24	9		
Half-breds	282	310	28	9		
Romney-Marshes	269	317	48	17		

The merit of the Romney-Marshes, in this stage of the trial, is, it is said, conspicuous. The South Downs are next, the Leicesters and half-breds being equal.

Sept. 7.		Weighted.	Gain per 100 lbs.
		lbs.	lbs.
	South Downs	316	5
	Leicesters	312	11
	Half-breds	310	8
	Romney-Marshes	337	6

The Leicesters here, it is observed, continue to take the lead throughout the summer. So long as the food is plentiful, they beat all the others; and this part of the experiment goes to prove a most important point, which has indeed been long suspected, that in good situations no breed is so profitable to the grazier. The half-breds are found the next to these.

The five remaining Romney-Marshes were sent to Smithfield on the 4th of July, and brought 48s. each; and on August the 7th, ten of the remaining Leicesters went at 48s. each, also seven at 40s. each; so that the profit for two years and two months food, added to the value of the wool, is, it is said, 5d. and a fraction per week for the Romney-Marshes, and from 4d. to 4½d. for the Leicesters, from the time of their being lambed.

The former part of the experiment will shew that the South Downs and half-breds in 64 weeks age gave 7d. per week profit; and that the Romney-Marshes and Leicesters, kept until they were nearly twice the age of the others, namely, 108 weeks the former, and 117 the latter, only gave a profit of from 4d. to 5d. per week. This is, it is said, a most interesting circumstance, and which manifestly tends to ascertain how much better it would be to the grazier to get rid of these sheep at an earlier age, and re-stock his land with those which are most saleable at the earliest period.

November 21st to December 25th. Weighed again.

	Weighted	Gain.	Gain per 100 lbs.
		lbs.	lbs.
South Downs	320	4	1
Leicesters	326	14	4
Half-breds	346	6	1
Romney-Marshes	331	lost 6	lost 1

This, it is supposed, is perhaps the most striking period of the experiment. By the last weighing, if turned to, it will be seen that the Leicesters had outstripped all the rest, and that the superiority is still maintained.

The above details of the practices of different districts, experiments, and remarks, must place the profits and advantages of different breeds of sheep for the purposes of the sheep-farmer, in a clear, satisfactory, and striking point of view. With respect to the wool of different sheep, we refer to the next article, and Wool.

*Different Kinds of Sheep-Management.*—In the practice of sheep husbandry, different systems are had recourse to, according to the extent and nature of the farms on which they are kept, and the methods of farming that are adopted on them; but under all circumstances, the best sheep-masters constantly

constantly endeavour to preserve them in as good condition as possible at all seasons. With the pasture kinds of sheep this is particularly the case; and with the view of accomplishing it in the most complete manner, it is useful to divide them into different parcels or lots, in respect to their ages and ferts, as by that practice they may be kept with greater convenience and benefit than in large flocks together, under a mixture of different kinds; as in this way there is not only less waste of food, but the animals thrive better, and the pastures are fed with much more ease. The advantage of this management has been fully experienced in many of the northern districts, where they usually divide the sheep-flock into lambs, yearlings, wethers, and breeding ewes; and in this method it appears not improbable that a much larger proportion of flock may be kept, and the sheep be preserved in a more healthy condition.

The nature of the management with a breeding flock is that the sheep-master must act according to his circumstances, situation, and the capital which he possesses, either selling the lambs to go to keep, fattening them for grass-lamb, suckling them for house-lamb, or keeping them on to be grazed and sold as store or fat wethers; the ewes being sold lean, as they are called, or fattened, as circumstances, profit, and convenience, may point out. Another practice, but which requires much capital, as well as knowledge, experience, and attention, is that of breeding and fattening off all lambs, both wethers and ewes, especially where markets for their sale, when fat, are conveniently situated. But where this system is too extensive, it may be partially acted upon, varying the plan according to capital, circumstances, and the nature of the times. In which case, whenever store stock becomes extravagantly high, it is mostly a good way to sell. But a method which is attended with the least trouble and hazard, is that of purchasing a store flock, as lambs, wethers, and what are termed crones, or old ewes; some of the last sort often proving with lamb, may be fattened off with them to good account. It is likewise often the case that ewes are disposed of in lamb, or with lambs by their sides, in what are termed couples, in which circumstances it is frequently a good practice to make annual purchases of them, in order to the fattening of both, and selling them in that state within the year. The system of breeding can only be had recourse to with effect and advantage in situations or on farms, where there are extensive tracts of land fit for the pasturing and support of these animals, but not the fattening of them; the more rich deep grass-lands being adapted to their fattening, and thereby affording a better profit, especially when quickly performed with a proper sort of this kind of stock, as that of good wethers.

But in the purchasing of sheep, which is often done from very distant fairs and markets, much care and circumspection are necessary, whatever the sort or intention with which they are bought may be. In these cases much advantage, especially when at a considerable distance, may be derived by employing a salesman upon the spot.

And the appearances which shew the sheep to be in a proper sound state of health, are a rather wild or lively briskness, a brilliant clearness in the eye, a florid ruddy colour on the inside of the eyelids and what are termed the eye strings, as well as in the gums, a saltness in the teeth, a sweet fragrance in the breath, a dryness of the nose and eyes, breathing easy and regular, a coolness in the feet, dung properly formed, coat or fleece firmly attached to the skin, and unbroken, the skin exhibiting a florid red appearance, especially upon the brisket. Where there are discharges from the nose and eyes, it indicates their having taken cold, and should be attended to by putting them in dry sheltered

situations. This is a necessary precaution also in bringing them from one situation to another while on the road.

It may be noticed that, with sheep-farmers, the common practice, except in particular instances, has been to leave the ewes for the purpose of breeding without any selection; but where good sheep-flock is the object, much attention should be paid in choosing such as are the most perfect, and that possess, in the highest degree, those qualities or properties which are wanted, whatever the breed or variety of sheep may be; as it is only in this way that a good flock can be raised and preserved. And it is a business that should always be performed at the time they are turned to the ram, if it has not been done before; and this is equally necessary in regard to the rams, that they may be adapted to the ewes. The author of the Farmer's Calendar has observed, that the late duke of Bedford, in attending to this object, had every ram with the lambs got by him the preceding year put in distinct pens, that he might not only examine them but their progeny, previous to his deciding "what ewes to draw off for him," which is certainly a method highly deserving of imitation by sheep-farmers in general. Such attention, united with a careful selection of cull lambs, must, the writer thinks, keep a flock in a state of progressive improvement, proportioned to the accuracy of judgment, eye, and hand of the farmer who practices it. And it is observed in the Agricultural Report of Norfolk lately published, that Mr. Coke readily assists, not only his tenants, but other neighbouring farmers, in sorting and selecting their South Down ewes, &c. and distributing them in lots to the rams according to the shapes and qualities of each. He puts on his shepherd's smock, and superintends the pens, to the sure improvement of the flock; his judgment is superior and admitted. The writer has seen him, and the late duke of Bedford, thus accoutred, work all the day, and not quit the business till the darkness forced them to dinner. See SORTING *Sheep-flock*.

Farther, it has been remarked in a late practical work, that the most advantageous and proper age for ewes taking the ram in the different breeds, has not been fully shewn; but from a year to a year and a half old may be sufficient, according to the forwardness of the breed and the goodness of the keep. Some judge of this by the production of broad or sheep's teeth. It should not, perhaps, be done while too young in any case. And in regard to the season of putting the rams to the ewes, it must be directed by the period at which the fall of the lambs may be most desirable, which must depend on the nature of the keep which the particular situation affords; but the most usual time is about the beginning of October, except in the Dorsetshire ewes, where the intention is suckling for house-lamb, in which case it should be much earlier, in order that the lambs may be sufficiently forward. But, by being kept very well, any of the breeds will take the ram at a much earlier period. Where the rams are young, the number of ewes should seldom exceed sixty for each ram; but in older rams a greater number may be admitted without inconvenience, as from one to two hundred; but letting them have too many should be cautiously avoided, as by such means the farmer may sustain great loss in the number of the lambs. It is found that the ewe goes with lamb about the space of five months, consequently the most common lambing-season is March, or the early part of April; but it has been observed, that in many of the more southern districts, where sheep-husbandry is carried on to a considerable extent, some parts of the ewe-flock are put to the rams at much earlier periods, so as to lamb a month or six weeks sooner; a practice which is attended with much profit and advantage in many situations where early grass-lamb is in great demand. It is usual for

the rams to remain with the ewes for a month or six weeks, and in some cases longer, in order to complete the business of impregnation, which in some districts is ascertained by smearing the fore-bows of the rams with some colouring substance. The method formerly in practice, and which is too commonly the case at present, of turning a number of rams among the flocks, is highly exceptionable, as tending to prevent the main object, and injure the rams. A better way is to let each ram have a proper number of ewes, and with very choice stock to keep the ram in an inclosed small pasture, turning a few ewes to him, and as they are served replacing them with others. By this means there is more certainty, and more ewes may be impregnated. In such sort of fine stock, it is likewise of great utility to keep the rams during this season in a high manner. In this view a little oats in the straw, or a mixture of barley and pea-meal, are excellent. Where ewes are backward in taking the ram, the best means to be employed are those of good stimulating keep. The rams should always be continued with the ewes a sufficient length of time. It is stated in the General Treatise on Cattle, that the ewe will breed twice and even thrice a year, if it be made a point to produce such an effect by attention and high keep, since she will receive the male indifferently at any season, and, like the rabbit, very soon after bringing forth. And that Lisle gives an instance of three of his ewes, well kept, lambing at Christmas, fattening off their lambs at Lady-day, and producing lambs again the first week in June. It seems they stole the rams immediately after lambing, but brought the second time only single lambs, although of a breed that generally produces twins. The former writer thinks there is no doubt but the sheep would produce young thrice a year, were the bad practice resorted to, which has been so currently recommended with the rabbit, of allowing the male immediately after parturition; the ready way to render both the female and her progeny worthless. Could the lambs be advantageously weaned at two months, sufficient time would, he conceives, remain for the ewe to bring forth twice within the year; for example, suppose the young ewe tupped in August, the lamb would be dropped in the middle of January, and might be weaned in mid March, the ewe again receive the ram on the turn of the milk, like the sow, perhaps in or before April, she would then bring forth within the twelve months, or in August. This plan would, he thinks, at least injure the dam infinitely less than suckling during gestation.

And it is necessary, that during the time the ewes are in lamb they should be kept in pastures, and as free from disturbance as possible, being carefully attended to, in order to prevent accidents, which are liable to take place at this time, such as those of their being cast in the furrows, &c. Where any of the ewes slip their lambs, it is advised by Mr. Bannister that they should be immediately removed from the flock. They also require, under these circumstances, to be kept as well as the nature of the farm will admit, in order that there may be less loss at lambing-time, from the ewes being stronger, and the lambs more healthy, and better capable of contending with the state of the season at which they may be dropped. At lambing-time every possible attention is to be paid. The shepherd should at this period be particularly careful and attentive to afford his assistance where it may be necessary. He should constantly have regard to the suckling of the lambs, and to see that the udders of the ewes are not diseased. His attendance will often be required in the night as well as the day. At this season covered sheep-folds are often of very great advantage, in saving and protecting both ewes and their lambs. And in respect to the number of lambs, it is remarked by the author of the

work on Live-stock, that the ewe brings most commonly one, next in degree of frequency, two, rarely from three to five lambs at a birth. This property of double birth is, he says, in some instances, specific; the Dorset sheep usually yeaming twins; and the large-polled Belgic sheep, with their descendants, our Teeswater, doing the same, and producing occasionally more at a birth. Other breeds bring twins in the proportion of one-third of the flock, which is supposed to depend considerably on good keep. A certain number of ewes *per centum* prove barren annually: the cause very rarely, natural defect; sometimes over-fatness, a morbid state of body, from poverty, or neglect of the ram; in other words, want of system in the shepherd.

Further, it has been recommended, that where rich pastures, or other sorts of good grass-lands cannot be reserved for their support, turnips, or other kinds of green food, should be provided for the purpose, and given them in a suitable manner; but where it can be done, it is always better to leave this sort of food untouched till about the period of lambing, when it should be regularly supplied, in proportion to the necessity there may be for it. The ewes also demand at this time much care, to see that they are put upon a dry sheltered pasture, free from disturbance, and that neither they nor their lambs sustain injury from the too great severity of the season. Whenever this is the case, they should be carefully removed into a proper degree of warmth and shelter, until perfectly restored. It is likewise a necessary, as well as a useful practice, as they lamb down, to take them and their lambs away from the common stock, putting them into a piece of turnips, or fresh dry pasture, where there is shelter when necessary, as by this means much fewer lambs will be lost than would otherwise be the case. It is also found, that by a proper supply of turnips, or other similar green food at this period, the milk of the ewes is much increased, and the growth of the lambs greatly promoted; which is of much future importance, as when they are stinted at this early period of their existence, they never turn out so well afterwards for the farmer. With the green and root crops, and preserved after-grass, hay, straw, corn, and oil-cake, are in some cases made use of in the winter support of sheep-stock. With turnips, where the soil is not sufficiently dry to admit the sheep, it is the practice to draw them and convey them to a sound firm pasture, that the ewes may be baited upon them once or twice in the day, as there may be occasion, care being taken that they are eaten up clean, as the circumstance of their being thus eaten may serve as a guide to the farmer for the supply that may be daily necessary. In this way this sort of food will be consumed with the greatest economy. Where the land is perfectly dry, and the intention is to manure it for a grain crop, eating the turnips on the land, by means of portions hurdled off as wanted, is a good practice. And with this sort of food, especially where it produces scouring in the ewes, green rousen hay, cut straw, or pease-haulm, should constantly be given, and also with rape, &c. Mr. Young has stated, that in some parts of the kingdom, the best farmers give their ewes and lambs bran and oats, or oil-cake, in troughs, while they are feeding on turnips; but he suggests, at the same time, that it must be a good breed for such a practice to repay. And it has been advised, when the weather is very wet, stormy, or there is much snow upon the ground, that the ewes and lambs should have hay given them in baits as may be necessary, which is mostly done in covered moveable racks, a portion being given fresh every day. It is, however, much better to have it cut into chaff, and given in troughs, as much less waste is made. There is still a higher practice of feeding made use of by some farmers, with ewe-stock of the

the more improved kinds, and which is said to have been found to answer better than the common keep in particular cases; which is that of employing parsnips or carrots with hay of the green rouen kind, or a portion of pea, bean, or barley-meal, also malt-combs, with potatoes and hay, &c. These sorts of keep are, however, obviously much too expensive, except under particular circumstances, and for the more improved breeds.

It is obvious, that where shelter can be provided, it will always be of much benefit to the sheep. But it has been observed, that the practice of letting them to the hay-stacks, which is common with some farmers, is slovenly and wasteful, and which, though it may afford a degree of shelter, should never be attempted when the other methods can be had recourse to. It has also been suggested by Mr. Young, as an excellent method, though not essentially necessary, to allow the sheep, whether the weather be bad or not, a small proportion of hay daily while at turnips. And it is supposed that by this careful management, and the use of flubble turnips when necessary, the ewe and lamb-flock may be well supported through the severity of the season, and be brought on in the best possible condition until the turnips are finished in March, which should always be the case when the preserved grafs or rouen may be ready to receive them; which is considered by some as the most to be depended upon through this and the following month, which, with the first week in May, is the most difficult period of the year to the flock-farmer. On dry meadows and pastures it is invaluable in this view, though at first sight it may have an unpromising appearance, from the covering of decayed autumnal grafs that is upon it; but which, when removed, presents a new growth of fresh green grafs, five or six inches in height, brought up by the shelter and warmth afforded by the covering of old grafs. This is found to agree remarkably well with the sheep, as they consume both together, having, as it were, both hay and grafs in the same bite. It is, indeed, supposed impossible to keep a full flock of sheep so cheaply in April by any other method as by this. Tolerable rouen will carry ten ewes an acre, with their lambs, through the whole month. Such rouen may be worth in autumn ten or twelve shillings an acre; in April it is worth thirty or forty shillings; and if it be a backward season, a farmer that has it would not be tempted to sell it for much more. But in the support of his sheep and lamb-flock, if the farmer be provided with a sufficient extent of watered meadow, he may fully depend upon that without any other provision for this period.

But in cases, however, where these cannot be fully depended on for the support of the sheep-flock at this difficult season, the most improved practice is, in place of depending on turnips and hay with rye sown for the purpose, young wheats, and the run of the pastures, to let the turnips continue, so as that their shoots may become an object of sheep food, and to have annually a portion of tolerable good land, sufficient to the extent of the flock, under rye-grafs and clover, so as to be ready in the spring to take the sheep from turnips, and support them till the time of turning upon the pastures. The same writer remarks, that this conduct is an improvement on the other, as it gets rid of three great evils: depending on rye, which is soon eaten; feeding on wheat, which is pernicious to the crops; and turning too soon into the general pastures. But at the same time that it effects this advantage, it is open to some objections, which make further improvement necessary. Keeping the turnips long in the spring is very bad husbandry. It damages greatly the barley crop, both in robbing the

land, and preventing it from being sown in proper time: nor is the food of great consequence, for many acres of turnip-tops are requisite, the number of which must be in proportion to the flock of sheep; and as to the roots, they grow so sticky and hard after the tops are at all advanced, that their value is trifling. With respect to ray-grafs, the clover mixed with it is seldom above three inches high at this season; and a great breadth of ground to a given flock must be assigned to keep the sheep through April. The number of acres of that young growth necessary to keep a hundred sheep and lambs, is, it is said, surprising; so that these farmers, although they manage to spring-feed more sheep than the work of their brethren, yet effect it at a great expence, and at last not in any degree comparable to what might be done. A turnip should never be seen on the ground after March. For the month of April the farmer should have a field of cabbages ready, which, yielding a great produce on a small breadth of ground, reduces the evil of a late spring sowing; and, if he manages as he ought, totally excludes it. The turnip-cabbage, and ruta бага, will last as long as wanted; and though they run to seed, yet the bulbs will not be sticky. The green borecole may be fed off several times: it is impenetrable to frost, and will make shoots in the winter. And another crop, continues Mr. Young, for feeding sheep in spring, which is of particular merit, is burnet. An acre of it managed properly, will at this season yield much more food than an acre of clover and ray-grafs. It should be four or five inches high in November, and left so through the winter. Burnet has the singular quality of maintaining its green leaves through the winter; so that, under deep snows, you find some luxuriance of vegetation. From November to February the crop will gain two or three inches in growth in the young leaves, and then be ready for sheep. It will be better in March, and if kept, ready in April, not only for sheep, but horses, cows, or any other stock. These systems of feeding and management are, however, in practice much varied according to the nature of the farm and the kind of sheep that are kept. In Norfolk, with Mr. Bevan's flock, which consists of forty-five score of the South Down kind, the following is the arrangement. The tups are put to the ewes about the 10th of September, for two months, being fed on the layers and pastures, and are folded on the old layers for wheat: after wheat-sowing they are folded on the pastures and layers till the time of yeaning, during which they lie on the pastures without fold, and have turnips thrown to them, with plenty of good hay. The fattening sheep are on turnips and hay, from Michaelmas to the end of March, followed by the hoggits. In April the couples go to cole-feed in hurdles; from cole to rye; from rye to the new layers, if forward enough, otherwise to the water-meadows, till the beginning of May; and from thence to the new layers, being still in hurdles, with a good deal of room to fall back, and continue so on the layers till about the 10th of June, when the ewes are washed for clipping, and until the lambs are weaned: the ewes then go to fold with the shearlings on the fallows intended for turnips, and the lambs are put to fresh grafs reserved for that purpose: all the sheep on turnips and cole having hay, they consume about twenty-five tons. The general winter provision is 80 acres of turnips, 20 of cole, and 30 of rye, for the spring. Mr. Bevan ploughs in his rye-stubbles before the flocks are carried to turn in the scattered feed, harrowing in half a peck of cole-feed for sheep-feed in the spring, and finds it of very great service. The latter, after feeding, stands for a crop. He values his turnips on the average at 30s. per acre, and cole at 25s. After turnip-sowing, the

## SHEEP.

stock is folded on old layers for rye, till the end of August, when the ewes intended for breeding are put to good pasture till the tups are let in. But in 1802, the tups now put to the ewes about a week later, and the lambs not weaned till the latter end of June. Provision this year, 100 acres of turnips, 30 cole, 30 rye, for 25 score breeding ewes, 15 score hoggrits, 20 tups, 10 score fattening stock; 51 score in all.

Turnips, as a holding-out winter food for sheep, are unquestionably excellent, particularly when not given in too large quantities, and with some sort of dry food with them, as sainfoin hay in this season, common hay, cut pea, bean, or wheat-straw. There is also said to be an advantage in having them drawn one or two days before they are used, in some districts, and even in having them stacked. But potatoes are thought a much better food than turnips in other parts where sheep are a great object, as being more fully and regularly to be depended on, and as preventing the diseases to which the animals are liable in a more effectual manner. The Swedish turnip come into use the latest, as in the early spring.

It is stated in the Corrected Agricultural Report of the County of Sussex, that general Murray fed 5000 sheep with potatoes and hay, 1651 of his breeding ewes ate 51 bushels every day, giving a quart to each; and which, for 120 days, is 6120 bushels: while the Norfolk stock-farmer provides for 720 sheep, 80 acres of turnips, 16 tons of hay, 20 acres of rye. The following is the comparison of the value, &c. of the provision.

It is said, that if 720 sheep require 80 acres of turnips, 2240, the upland flock at general Murray's, will require 248 acres of turnips; but they have only 50. That if 720 sheep require 16 tons of hay, or 10 acres, 2240 should require 49; instead of which they have 120, which is 71 surplus, or, at one load and an half the acre, 48 acres. And that, if 720 sheep require 20 acres of rye, 2240 should require 62, instead of which they have none at all.

Which is, it is said, a difference of 63 per cent. This vast difference is to be attributed, it is supposed, in a great measure, to the distinction between the breeds of the flocks, as one being the Norfolk, and the other the South Down, as all the circumstances are in favour of it; but it may be partly owing to potatoes being a cheaper food than turnips. As to the feeding of sheep with potatoes, however, it is, though ascertained on the above farm on a very large scale, a more disputed and doubtful circumstance; and for this reason, they are allowed, stinted, or limited in their consumption, which is not the case with turnips: these, on the Norfolk farm, are fed off on the land, and, of course, in the greatest plenty. The other accidents and objections to which they are constantly liable, are also not to be overlooked: while potatoes are a regular certain crop, and subject to few accidents or inconveniences. When these circumstances are therefore well considered, in the pinch of a severe season, it will be readily agreed that the introduction of this root, and the proof of its advantage by the above extensive trial, as a winter and spring provision for sheep-stock, is really important.

The quantity of a quart every day of this root for each sheep is probably, however, much too small, as in fattening them with it in suitable yards for the purpose, a far greater quantity has been found necessary. But lean sheep certainly do not require the same proportion for keeping them as is requisite in the fattening system, as may be seen below, in speaking of that sort of management.

Cabbages, as a food for sheep, are of great importance and utility in many situations, particularly in those where the land is suitable for raising them, though it may not be of the very rich quality. They are of vast service in carrying on improvements in sheep husbandry, and as the means of keeping a greatly increased stock, where good management is followed.

The artificial grasses, such as ray-grass and red clover, are of much consequence as spring food for sheep; the first is early, and comes in after common turnips, when much wanted. It may be cultivated to advantage when the latter will not succeed. The clover comes into use in this way at a later period, and on stronger descriptions of land. Many other grasses of this sort, as well as some of the natural grass kind, might be very beneficially grown in this intention, as the cock's-foot in some cases, sainfoin, &c. on soils of the calcareous kind, and some of the peas and alopecurus, in other circumstances; by which means earliness, quantity, and quality of keep might be secured.

Tares, rye, and cole, are in great request as spring food for sheep-stock, the first being raised on the stronger sorts of land, the second on such as are of a lighter quality, and the last on many kinds, even the hilly calcareous sort. They are all sufficiently early for being fed in April, or the following month, when turnips are done. Spring tares are likewise often put in to be fed off at the close of the autumn. These practices answer very well; but mixed crops of tares and rye never do well for the purpose of sheep-feed; as they do not by any means come well together, of course there is much loss. These and other mixed crops are, however, frequently had recourse to in this sort of management, with evident benefit.

The stubble turnip system of food is very good in this sort of husbandry, for late spring or other feed; where crops of such kinds take well in succession to those of other sorts.

The plan of preserving after-grass for the purpose of sheep-feed is certainly very useful, especially for the support of ewes and lambs in the early spring. It provides well for the time of scarcity.

The practice of converting young wheat crops to spring sheep-food is seldom good. It is mostly the business of necessity and want of forecast in the sheep manager. On light and dry lands it may occasionally be useful, but it often does much harm.

Winter barley, and some other sorts of crops, have also been tried as sheep-food, but hitherto only by particular individuals on a small scale.

Whatever the nature of the food which is raised with this design may be, it should always be provided in ample abundance to the quantity of sheep-stock which is to be kept, as no sort of pinching ever answers any good purpose in this management. Good water should likewise be constantly attended to in this practice.

By thus cultivating proper quantities of proper sheep-food in connection with the keeping and managing of flocks of this sort, many important benefits and advantages would necessarily result, a far greater quantity of sheep would be kept on the same extent of ground, they would be preserved in a much better state of condition, and they would be in a much more desirable situation for the purposes of breeding or being fattened, and consequently be in every way greatly more profitable to the sheep-farmer; while the growth of such sorts of food would prepare admirably for grain crops, by which little expence would be incurred. Besides these, it would contribute in several other less important ways to the benefit of the flock-farmer, in many cases and situations.

And it is observed that, by the means which have been stated above, the sheep and lambs are capable of being continued in good healthy condition, a matter of great consequence to the flock, until the period of turning on the pastures, when they should be separated, where the lands are inclosed, into proper divisions, in proportion to the quantity each pasture can support, care being taken not to over-stock the fields, though hard flocking in some cases may be beneficial. With some farmers they are put upon the richest pasture of the farm, while with others it is the custom to let them have those of the inferior kinds. This must depend much upon circumstances; but whatever mode is adopted, the point of having the flock preserved in good condition is never to be lost sight of. It is advised, that in keeping sheep on inclosed pastures, particularly where the lands are much occupied with wood, constant care is necessary, in order to guard against the mischief of the fly, as its effects are often irremediable in the course of a very short

time in such situations, if not attended to, in hot seasons. With the view of fully guarding against this insect, a very frequent and particular examination must be made by the shepherd.

Further, on this subject it may be noticed, that the next circumstance in the management of these animals is that of weaning the lambs, which is a business that should be effected when they are three or four months old, as about July, but it is done more early in some districts than in others. And to effect it in the best and most beneficial manner, a proper reserve of some fresh pasture grass, where there may be a good bite for the lambs to feed upon, should be had recourse to, as it is of much consequence that an ample provision of this sort be had, in order that the growth of this young flock may not suffer any check on being taken from the mother. Where they have been continued so long as to graze with the dams, little check will be sustained in their separation, if turned upon such good feed. Some advise clover in blossom as the most forcing sort of food in this intention, and with others sainfoin rouse is highly valued for the same purpose. When good feed is not provided, of some of these kinds, the lambs soon decline in flesh, or in the technical language of the shepherd, the flock are said to *pitch*; and when once this happens, they never afterwards thrive so well, however good the management may be. With regard to the ewes, they should be removed to such distant pastures or other places, as that they may not be heard by the lambs, which would cause them to be disturbed in their feeding. And where the ewes sustain any inconvenience from their milk, as by their udders swelling, it should be drawn once or twice, as by this means bad consequences may be prevented. And as soon as the lambs have been removed, the ewes are returned upon the pastures destined for their summer support. There is, however, one caution to be attended to in first turning the lambs upon rich keep, which is that of letting them be in some degree satisfied with food previously, that they may not be surfeited by too quick and full feeding, and *beave* or *bove*, as it is termed; keeping them gently moving about the field has also been advised in this intention. In some places where the lands are of the more poor kind, it is a custom to send the lambs to the more rich vale or marsh districts, to be brought forward in condition, or fattened. In those cases, where the lambs of the male kind are reared on the home lands, as wethers, they are usually restored to the flock in the latter end of the year, but which is not by any means a good practice, as they often suffer for want of proper keep in the winter, and lose what they had previously gained in growth and condition.

And in the usual management of sheep-flocks, it is the common practice to remove a certain number of the old ewes or crones every year, replacing them by the best lambs, in order that they may be kept up in the greatest perfection, it is, of course, a matter of considerable importance to have this done in a proper manner. And in almost all the sheep districts in the southern part of the island, this selection, or *setting* of the *lamb-flock*, is performed about August, at which period the fairs for the sale of lambs mostly take place. And as at this time the whole are collected together for drawing into different lots, it is a very suitable period for selecting or choosing those that are to supply such deficiencies in the breeding flocks. In his Calendar of Husbandry, Mr. Young has well remarked, that in making this selection, the farmer or his shepherd usually (whatever the breed may be) rejects all that manifest any departure from certain signs of the true breed: thus, in a Norfolk flock, a white leg, and a face not of a hue sufficiently dark, would be excluded,

however

## SHEEP.

however well-formed; in the same manner a white face on the South Down; in Wiltshire, a black face would be an exclusion, or a horn that does not fall back; in Dorsetshire, a horn that does not project, &c. &c. And where the produce is annually sold lean, there is, he maintains, reason in all this; for customers who have been used to and prefer certain breeds, as having paid them well, are apt to be fastidious when they purchase. Some farmers in this selection look chiefly at size, always keeping the largest frames; but this is probably erroneous, unless they keep very high. It connects with a question by no means ascertained, whether sheep do or do not eat a quantity of food proportioned to their weight? In general it is a safer rule to choose a well-formed lamb, or that indicates the probability of making a well-formed ewe, rather than to select for size. The attention that is to be paid to wool in the breeds that produce the carding sort, will depend on the price to be received: if the farmer lives in a district where the price of the year is given equally to all flocks, there is little encouragement to lessen quantity for the sake of quality; retaining, however, in idea, the fact that both are attainable, that it is very common to see coarse *breeched* sheep with light fleeces, and those of a fine quality heavy in weight. The Spanish fleeces, which are finer than any other, are heavier than those of our finest woolled sheep. With combing wool the importance of the fleece depends still more on price; we have seen it at 8s. a tod: and it has lately been 36s. Quality is of very little consequence indeed, compared with quantity; and when wool sells high, no prudent breeder will set his flock without being governed considerably by this object. And it is added by the same writer, that the high prices at which new Leicester and new South Down rams let and sell, has opened a field of speculation in sheep-breeding. It is sufficient to remark, that this spirit of breeding, whether it shall prove durable or not, whether much money shall or shall not be made in it in future, is not what any prudent man beginning business will adventure in, but with great caution: men of such immense fortune are now taking a lead in it, and are in many respects doing it on such liberal principles, that the wisest conduct of such farmers as he may be supposed to address, is to take proper opportunities of converting their experiments to their own (the farmer's) profit. Leave the expence to them; but, when you can, convert the profit to your own advantage. In setting a flock of lambs, therefore, you may mark a score of the best, for a future ram to be picked up when opportunity offers; or, better still, to send to the top of some ram-letter that takes them in at a reasonable price *per* head. By every year selecting five or six *per cent.* and by every year covering that number by a ram better than your own, the flock must be on the improving hand; and this may be done at a very small expence. Also at this period, besides filling up the deficiencies in the ewe-stock, the increasing or diminishing the quantity of stock usually kept, by reserving a larger or smaller number than that of the old sheep which are disposed of, is also a point that demands particular notice. Mr. Young has given the following useful directions on this subject, in his *Calendar of Husbandry*.

On a farm, says he, with a given stationary sheep-walk, it is probably regulated by circumstances that rarely change; but on inclosed farms, where the sheep are supported by fields alternately in grass and tillage, variations may easily be supposed, and the question of hard or light stocking, that is of close feeding or a head of grass, then comes in to decide the number kept. If the produce or profit *per* head is looked to, the conduct to be pursued is evidently to stock lightly; but if the return is looked for in corn from fields

laid down for refreshment by rest, then close feeding is a very material point, and the number kept will depend on it. With all grasses, &c. that do not decline from age, the more sheep you keep the more you may keep, and the more corn you will reap when such are ploughed; a circumstance too important to be forgotten. But the young farmer will remember, that upon this system he must not have a *stow* flock, or let the variety of a farm have the least influence with him: if in this way he will have a something to talk of, a score or two of pampered favourites, the fewer the better, for they may cost him more than they are worth.

And as soon as this has been properly executed, the ewe and wether lambs that are left are mostly sent to the neighbouring lamb-fairs to be sold off. But where the fairs for this purpose happen later than the above period, as in the beginning or latter end of September, as is the case in some situations, it has been advised by the writer first mentioned, that great care be taken to keep them in forcing food, as in spring tares, early sown rape, good grass of the right degree of bite, &c. &c. in order to promote their growth and increase their value; but to sell in August is more beneficial.

It cannot but be obvious, that in the management of breeding flocks, the lambs come to be disposed of at different periods; first those that have been suckled or fattened in the house, in which system of fattening, much attention is required to have them early, to their being well, regularly, and very cleanly kept and suckled, as well as to the ewes being of the right sort, and the best milkers that can be provided, and to their being fully supplied with food of the most nourishing and succulent kinds. Their tails and udders should have the wool clipped away from them in order that they may be preserved in a perfectly clean state. The lambs also require, especially towards the close of their fattening, to have regular supplies of barley, wheat, and peas, meal ground together in combination with fine green rouse hay, &c. See *LAMB-Suckling*.

And as soon as these have been sold off, the lambs which have been fattened on the best grass-land will be ready to succeed them at the markets, in the spring and summer months, and these will be followed by the sale of the store-lambs at the different autumnal fairs.

Further, there are different local practices also adopted in different counties, to suit the particular methods in which their sheep husbandry is conducted, as well as the particular objects of it. The following is given as a hint from sir Joseph Banks, by the writer of the Lincolnshire Agricultural Survey, on the sheep system of that extensive district: that as tups are there always hired by the breeders, the lambs may be said to be purchased before they are born; a year's credit, however, is given on this occasion, they are not paid for till the actual value can be fairly estimated; if, therefore, any one who has hired a tup at a considerable price, finds the lambs he has got not sufficiently above the ordinary sort to pay him the difference, with interest, he complains to the tup-man, who generally views the lambs with him, and makes a fair abatement, which is generally settled in the price of the hire of the next year's tup; this regulates the price of letting, and makes the tup-men a most useful set of people. The great mass of breeders in Lincolnshire sell their heeder lambs about old Michaelmas time, or a little after: a succession of fairs for that purpose are held in a village called Partney. These lambs are resold in the spring at Lincoln fair, under the name of hogs; at Midsummer their owners clip, and then winter them; the succeeding spring they are carried to Boston, where, in a long succession of markets, they are sold to the graziers, with their wool

## SHEEP.

wool on, under the name of shearlings, and immediately turned into the marsh to fatten; the graziers take their fleeces, and having wintered them, get the kindliest to Smithfield in the course of the succeeding spring; those that do not fat so easily, yield the grazier a fleece at Midsummer, and are got off the ground in the course of the next autumn. Here you see a combined system of sheep agriculture, for as the animals are eternally either changing hands or yielding fleeces, they make a return of some kind or other to their owners, nearly half-yearly from the time of their birth, to that of their final dissolution at Smithfield. See RAM.

In the sheep system of management which is practised on the large rich tracts of the Romney, Walland, and Denge marshes in the county of Kent, there is also a local peculiarity and difference which is worthy of notice. The usual practice with the lambs in these marshes, is that of sending them about the beginning of September to be kept by the neighbouring upland or hill farmers during the winter. They go in separate lots, being received at certain appointed places by the farmers, and driven to the houses, or taken to the farms by their servants. They are then commonly put upon the stubbles or *grattons*, as they are called; but in some cases they have also pastures to run upon, though too little attention is, in general, paid to the changing of them, by which they suffer much, and are often greatly injured, especially such as are weakly and delicate. Much advantage would probably be gained by having them put, in separate lots, in different fields, and by giving them in wet seasons, once a day, some sort of dry food, such as hay, or those of better kinds in particular cases. It is not improbable, indeed, that lambs might be safely kept in these marshes through the winter, by the use of such food and proper care. It is found that there is a prodigious benefit in keeping the lambs in winter, in such situations, in having the grounds dry and warm, instead of being of a cold, wet, clayey nature. Lambs should by no means be stocked along with the ewes, as the old sheep will constantly take the feed, and *stench* the land, by which the lambs may be greatly hurt. They should always be stocked separately, and the pastures be frequently changed, circumstances which are little regarded here. Some think that lambs do not thrive well on being put to graze, after having been fed on luxuriant food, such as turnips, old tares, rye-grass, &c.

The price of the keeping of lambs in these cases is very different; some paying only 4s. 6d. the lamb, while others pay 5s.; and where no neat flock are kept, they charge as high as from 6s. to 6s. 6d. the head, for the space of about six months. This is but a late advance; however, it makes the price of keep a serious object. The loss of lambs in this system of winter management, is occasionally considerable, but depends much on the nature of the season, as to mildness or severity, amounting in some cases to four or more in a hundred.

The tegs, or one-year old lambs, in this system are brought from the uplands, where they have been wintered too often in a low state of condition, for the supply of the marsh graziers, which enables them to keep more ewes and fattening-sheep on the marsh lands. This is done about the beginning of April, when the upland farmers are indulged with a feast or treat at the expence of the graziers, as a recompense for their care and attention to the lambs, in which liberality has a great effect. As the flocks reach the marsh, they are put upon the poorest pastures, at the rate of five to the acre, their old sheep being just sold to make room for them. These are commonly the best conditioned tegs, in which there may sometimes be loss from the

fudden transition from poor to too good keep, though they are not, in general, so subject to some sorts of disease as the old ones, on such changes being made in their food.

The marsh sheep-graziers have lately been much in the practice of prevailing on the farmers to keep such flocks a fortnight, or even double that time, on turnips, which has the advantage of enabling them to double the stock on the same pastures during the summer; while on the other hand, it is evident, that when they are so hard stocked early in the spring, they can neither have so luxuriant a growth, nor be so full of grafs. The pastures are likewise eased gradually, as the fat ewes or wethers are taken off, and their places supplied by the wether-tegs, while the ewe-tegs are suffered to remain on their original pastures, until they are selected, or set for going to the rams.

In the ewe management of the marsh system, which is by no means well regulated, the ewe-tegs, one-lamb, two-lamb, and three-lamb ewes, are all mixed together, so that they cannot be distinguished by the grazier, as they are not marked until turned off for fattening. A better and more convenient way would, however, probably be to keep the different kinds separate as much as possible, as many advantages would result from it. In winter the land is stocked in proportion of from two to three ewes on the acre, as it may be of a more or less good quality, and in summer with from three to four and their lambs. In case of twin lambs, with not ever more than three to the acre upon the bell pastures. The summer stocking with ewes is here supposed to have too much uniformity in it, though it may perhaps be proper in the winter, yet when that season is mild more might certainly be kept than under the contrary circumstances, for which no sort of allowance is made. It is conceived, that it would be good policy, when there is the probability of plenty of keep, to increase the number of ewes on the breeding pastures, though there should be a necessity, on that account, to provide an additional pasture field or two; however, so prejudiced are many sheep-farmers in favour of the common practice, that they do not even make the necessary additions of stock to keep the grafs properly under, by which means it is apt to become benty, the pasture injured, and considerable waste sustained. The old sheep, or those which have had the third lamb, are commonly cait off for fattening, and the others marked for stores, and weaned from their lambs, by putting them into one of the pasture fields for some days; which not only improves the field, but prevents the ewes from receiving injury by the flow of milk. This is a practice which in the marsh management is termed *bleating* the ewes. Some reject this mode, and put the ewes immediately on the fattening ground, from the conviction that more injury is likely to ensue by keeping them in a starved condition, for even a short time, than by throwing them at once into fresh keep. Whichever of these is the most eligible practice is not attempted to be decided, but the most general one is that of bleating: aged sheep are not so liable to be struck with disease as young ones in such cases, or the season of the year so favourable.

The system of the marsh for the management of the wethers, and the time of drawing them for the market, is this: the wether-tegs are in the general practice put upon the fattening land for the winter about Michaelmas, in the proportion of from two to three upon the acre, as may suit the designs of the grazier. Those who intend to keep them for a whole year, commonly put three on each acre of the bell pastures for the winter flock; but those whose intention is to make a second or third return, are satisfied with two on the same extent; in which case, however, it is necessary that they be put more early upon the land, in order that they

may

## SHEEP.

may get properly fat before winter, and go off sufficiently early, which would otherwise not be the case. The latter method is thought unquestionably to be the most profitable; but those who have not a sufficient supply of summer pasture, conceive that it will pay them better to keep three to the acre, in barely a thriving state, and fatten them in the following spring and summer. However, though they may continue to increase in size, it is most likely they will not be of more value at Michaelmas than they were in the spring; so that there is a clear loss of the whole summer keep: as mutton may often sell for 6*s.* or 7*s.* the stone in the spring, and not bring more than from 4*s.* to 5*s.* at that period in the autumn. It has been long a question, whether other sheep or old barrens fatten the most quickly, on which it may be noticed, that any increase in the food of full-grown sheep must have a tendency to the formation of fat, whereas in wethers or other young sheep, it must be partly expended in the evolution and development of their frames, and, of course, less fat be produced. Much, however, will depend upon the size and disposition of the sheep.

There is great difference in the practice of different graziers, in regard to the time and manner of drawing the sheep for the market, some beginning much earlier than others, though the sheep were all put into the fattening pastures at the same time. Some draw the worst of the sheep first, conceiving that the prime sheep pay the best for keeping; while others send them to market as they get fat, by which means, time is given for the advancement of the more common ones. Which of these methods is the most to be preferred, it is not at all attempted to determine; but the sending of inferior mutton to market, it may be remarked, is only giving it away, while, on the contrary, the retaining of such sheep as are deficient in disposition to fatten, is a complete loss of the keep of them. Towards the end of the summer, keep, however, is of but little value, and, of course, their remaining a little longer is not of any material consequence. It is therefore thought, perhaps, the best not to part with them until the approach of autumn, when inferior mutton often sells well in the vicinity of the marsh, or to dispose of them to lamb butchers at a somewhat reduced price. This inconvenience would, however, be much removed by a better and more proper selection of the sheep than that which at present is the case.

In sending the sheep to market, care should be taken to have them as nearly as possible of the same size and condition, as a few inferior ones are apt to lower the value with the butchers. In this intention they are by some divided into two or three lots, while others send them in one only; the former, however, in general obtain the highest prices. By more attention to the regulation of size and keep, a greater equality would be met with in the wether sheep on the fattening pastures of the district than that which at present prevails.

In the system of these marshes, the ewes which are designed for breeding ram-lambs from, are selected and drawn before the *riding* time, as directly upon the weaning season, or a few weeks previous to giving them the ram; there being great differences in the forms and sizes which are thought the best calculated for this purpose, in the notions of different graziers; some preferring large, others middling sizes, while many esteem most, such as have long legs and bodies. There is here, however, much too little principle in the management of this business. Such ewe lambs as come from ram-lamb ewes, should be so marked as to distinguish them, and be constantly preferred for breeding ram-lambs from. The ram-lamb ewes are mostly lambed by themselves, and have superior keep. Those which do not suit the intention

of the grazier are castrated; while such as are to be saved have a small part of the tip end of the scrotum cut off, and two marks fixed upon them, one on the shoulder and the other on the hip; being constantly indulged with the best fattening keep, as it is the common opinion that they cannot be too large. They are sent to particular situations on the neighbouring hills during the winter season, where they are tended with the utmost care and circumspection, having hay and turnips occasionally given them. On being brought back to the marshes in the spring, they have the run of the best pastures, being stocked so lightly upon them, as to be in every way disadvantageous to the grazing farmer. Another selection sometimes takes place from them during the summer, in which, those which do not suit are either sent to market, or *netted*, while those which are approved are employed in the ensuing riding time. These young rams should only have a few ewes, as thirty or forty; as more greatly injures their growth, &c. They are usually fold or hired out, by which much money is often made.

It is the practice here to keep too many rams together in the same pasture, as much loss is sometimes sustained by it. The usual time of putting the rams to the ewes here is about the middle of November, though some prefer a month, and others a week or a fortnight sooner, as their notions may be in regard to the conveniences of lambing and other matters. A week or two before the riding time the ewes are prepared by being put into the larger fields; only one ram being admitted in each, unless it be so large as to stand in need of two, when with the old ram a young one is admitted. This management prevents fighting and all inconveniences of that kind. The rams commonly remain with the ewes a month, care being taken that they perform their business properly; some change the rams occasionally, as after the first fortnight, and at other times according to circumstances. Sixty ewes are usually allowed to an old ram, and thirty to a teg ram in this marsh system. See *Stocking Land*.

It may be observed that there is some difference in the method of managing heath, down, and mountain flocks of sheep, from those which are pursued on the inclosed pasture lands, though in the selecting and providing the rams and breeding stock, the same practices are followed by the best sheep-masters. The principal difference consists in the manner of keeping them, by putting them as early as possible in the spring months, as in the beginning of April, upon the downs, heaths, and commons, and keeping them upon them until the approach of the autumn, as the beginning of October; the fine soft sweet herbage in these cases preserving them in a state of tolerably good condition. And where it begins to grow scanty and decline in goodness, other sorts of feed which have been previously provided are had recourse to, such as turnips, cole, &c. on which they are folded during the autumn and winter till consumed, when hay which has been stacked for the purpose in such situations, is employed until the grass has again advanced to a proper bite. In these cases the system of folding is generally recurred to during the whole year, in the summer and autumn chiefly on the ground in a state of preparation for the wheat crops, but in the winter season often on the flubbles, though more extensively upon the downs and pastures; while in the spring season the lands under preparation for the barley crops receive them. This system is considered as very beneficial by the farmers in those districts where it is in use. And in the more hilly and elevated situations in the northern parts of the kingdom, other methods of management with this sort of stock are employed. In Argyshire the principal circumstances attended to by the most intelligent sheep-farmers are these: to stock lightly, which will mend the size of the sheep,

with

## SHEEP.

with the quantity and quality of the wool; and also render them less subject to diseases. In all these respects, it is allowed by good judges, that 500 kept well, will return more profit than 600 kept indifferently. To select the best lambs, and such as have the finest, closest, and whitest wool, for tups and breeding ewes, and to cut and spray the worst. To get a change of rams frequently, and of breeding ewes occasionally. To put the best tups to the best ewes, which is considered as necessary for bringing any breed to perfection. Not to tup their year-old ewes; which, in bad seasons especially, would render the lambs produced by them of little value, as the ewes would not have a sufficiency of milk; and would also tend to lessen the size of the flock. To keep no rams above three, or at most four years old, nor any breeding ewes above five or six. To separate the rams from the 10th of October, for a month or six weeks, to prevent the lambs from coming too early in spring. To separate the lambs between the 15th and 25th of June; to have good grafs prepared for them; and, if they can, to keep them separate, and on good grafs, all winter; that they may be better attended to, and have the better chance of avoiding diseases. A few, whose possessions enable them to do it, keep not only their lambs or hogs, but also their wedders, ewes, &c. in separate herds; by which every shepherd, having his own charge, can attend to it better than if all were in common; and each kind had the pasture that best suits it. But in Linton, the following management, according to the survey of that district, is observed: in summer the flock is divided into three *herds*. In the first are all the hogs and yield sheep; in the second, the milk ewes; in the third, the lambs. In winter they are kept only in two *herds*. In the one are the hogs, in the other the ewes and yield sheep. The lambs are weaned about the end of June, the ewes milked from the 1st of July to the middle of August, and the milk made into cheese. The sheep are clipped from the end of June to the end of July, according to the weather and condition of the flock. The tups are let to the ewes from the 15th to the end of November, according to the situation of the ground, and the nature of the grafs. From 40 to 50 ewes are allowed to one tup. The breeding flock is changed every five years, by selling off the superannuated ewes. Some ewes, however, are kept longer than five years, and some shorter, according to their condition; for they do not all decline equally soon. In East Lothian, sheep are in much esteem, and kept in considerable numbers every where, especially on the coast lands. Permanent flocks, however, and regular sheep management, may be said to be almost confined still to the higher parts of the country. In the low country they are kept chiefly to eat the turnips, and sometimes fown grafs, which is permitted to be a year or two for pasture. Flying flocks therefore are generally kept, and as soon as they are fattened for the market, which is usually within the year, they are sold off. A considerable number of lambs likewise are reared, only so far however as to render them fit for the butcher, or to be sold fat. But as the great object, in the lower districts, is feeding, little attention is paid to particular kinds; every farmer keeps those which he thinks are likely to pay best for the food which they consume. The black-faced, or Tweeddale breed, are most generally preferred for feeding on turnips, because they are most esteemed in the market; but many of the Cheviot breed are likewise kept, and even some of the improved Leicesters.

It may be noticed that it is, however, only in the Lammer-muir district that sheep husbandry can be said to be regularly practised, the management of which is this, according to Mr. Hay of Hopes. All store-farmers of any

extent keep two flocks, *viz.* one of ewes, and another of yield sheep; and this flock they sometimes divide, and have a flock of what is called *hogs*, that is, lambs of one year old. The common practice is to fold the ewes upon a break of arable land, during the summer: they cut the lambs about the 26th of May, and they wean them in the first week of July, and then they shear the whole flock. The lambs, after weaning, are sent to a healthy pasture, called the *burn*, which has been kept for them, where they remain till the end of August; when they are moved down to the best low pasture, called the *hog-fence*, which has been saved from the weaning; and here they remain during the winter. The ewes are milked for about eight weeks after the weaning, and sometimes longer, and then are put out with the lambs into the *hog-fence*, for the winter. All the sheep are smeared, that is salved, immediately after the harvest, at the rate of two pounds, iron weight, of butter, to a Scotch pint of tar, which salves from six to eight sheep, at the expence of about five-pence each. The wool sells at from five shillings to eight shillings *per stone*, iron weight; and usually takes from six to eight shillings to a stone; so, deducting the expence of salving, the net proportion upon the wool may amount to from eight-pence to ten-pence *per head*, sometimes a little more or less, varying according to the price of wool. Upon dry heathy grounds, the ewes are drafted, and sold to graziers, in the month of March; but upon wet grounds, which are dangerous, and subject to the distemper called the *rot*, they are drafted and sold in October. Few store-masters (tenants) in Lammer-muir breed as many sheep as keep up their flock; so they have to buy yearly a parcel of hogs, which are mostly wedders. Linton, in Tweeddale, is the great market for these wedder hogs. These wedders they keep for two years, and sell them to the feeders. Some of the most judicious store-masters have totally given up the practice of milking the ewes, after weaning; and others milk for a shorter space than formerly; and they now allow the lambs to suck longer, which considerably increases their bone, and is thought not so pernicious to the ewes as the milking. This practice, however, still prevails in Wales; the cheese made from ewe-milk being highly esteemed, such milk being said to be four times as rich as that of cows. The sheep are stated to give a quart of milk *per day* each, and being milked three months, the return is stated at ten shillings *per ewe*.

It is also further stated by the writer of the above Report, that the method of managing the arable land in that district has been changed much for the better, within these few years. When in grafs, it is folded; and when taken up, it gives three crops; and is then fallowed, and sown out, the first crop with grafs-seeds; and they generally follow the same practice with the new grounds taken in by fallow and lime, which has now become a general practice through Lammer-muir; and lime, when applied to dry ground, is certain of making a lasting improvement upon the grafs, which is, and always ought to be, the great object upon store-farms. However, since this account was given, much improvement has been made in this sort of husbandry, which is now carried on in a very systematic manner, it is said.

It is worthy of notice, that the practice of *finearing* or salving is now, even in these situations, much on the decline; and in the more southern parts of the island, not at all employed. See *SALVING of Sheep*.

In the sheep districts, in the more elevated and exposed northern parts of the island, a still inferior practice is had recourse to; the sheep being mostly left to provide for themselves, even in the most severe and inclement seasons, when

## SHEEP.

when the bleak tracts on which they live are deeply covered with snow. According to the writer of the Perthshire Agricultural Report, in these cases the sheep have their chief dependence for subsistence on their own habits, which lead them to remove the snow by their feet with great facility, till they reach the heath or withered herbage. But when the snow is falling, or blown by a storm, the shepherds drive their flocks, without intermission, round the top of a hill in a circle, in order to keep them from lowering, and being drifted up or smothered. It has been the practice, in some districts, to erect a sort of circular folds on the tops of low hills, for the same purpose; and when the heath is all covered, they sometimes rake or harrow the snow, in order to bring up the heath, with a sort of long-toothed rake or small harrow. With some sheep-farmers it is the mode to have recourse to feeding with hay, or unthreshed oats, which is deposited in handfuls upon the snow. Mr. Marshall has suggested, that cultivating plots of furze, broom, juniper, &c. by sod-burning, and rippling the surface, or by other more eligible means, could not fail of proving beneficial upon the wintering grounds of a sheep-farm. By means of these, as a resource in the deepest snow, when the herbage of the *bræs* was buried too deep and too evenly to be uncovered by the scraping of the sheep, by keeping the most exposed part of the *bræs* in full herbage for less general coverings of snow, and by reserve of rape for the season of lambing, even ewe-flocks might be supported through the winter with some degree of certainty, without dry fodder, and without being left to the uncertainty of the seasons, and the mercy of the winds and weather, as they are at present.

The practice of *hirfelling*, where no more lambs are kept than what is necessary for drawing the stock, is now much objected to by some, though it may be beneficial in rearing wether hogs; as they are found not only to do much better, when at large with the ewes, but there is much less destruction of grass by trampling, and the pastures are fed down more properly, and with less injury to, and loss of, the sheep. Besides, the sheep thrive better, and are kept in far better condition, while much less herding is required, by which there is a considerable saving of expence.

There are several different modes of rearing the lamb hogs in these situations; as by laying them, when lambs, upon a certain part of the ground, and keeping them separate from the old sheep, through the whole winter and spring, until they are clipped; and then blending them again with the old sheep, putting more lambs upon the same ground, &c.; by allowing the hog lambs, when gimmers, to remain upon the same land on which they were bred, and breeding the hogs on a different part of it, and continuing them on that also until they are gimmers or dinmotts, and then introducing them among the old sheep, the lambs being every year laid on the land where such gimmers or dinmotts had been the previous year; by keeping the hogs and dinmotts or gimmers together, and putting the gimmers or dinmotts only among the old sheep, and the lambs among the hogs, in the same place, &c.; and by breeding the hogs among the old sheep. The three last of these modes of management are supposed the most useful, but the last the most powerful in preventing disease; though the first and second probably afford the most equal stock of this description, in such exposed situations.

*Profits of Sheep-Management.*—It is evident that there is a variety of circumstances in the practice of sheep husbandry, that must affect any statement that can be made, in respect to the profit that may be derived from it: the nature of the system of management pursued, and that of the breed of

sheep employed, must operate so much in this way, as to leave the profits of no two sheep-farmers scarcely the same. But our limits will not allow us to introduce any particular statements on the subject.

In all sorts of sheep-grazing management, it should be the constant aim of this kind of farmer to have his pasture or other land so stocked and provided, as to derive the greatest possible profit from it; as where this is not the case, he not only injures himself, but the whole community. Where systems and practices of this nature are followed, which are not sufficiently profitable, they should be given up, and changed for such as are more fully beneficial. The same plan cannot, however, be always equally productive of advantage, as the fluctuation in the value of stock in different places, and from the ease or difficulty of providing it, at different times, as well as the nature of the season; must be the causes of much diversity in it, which are invariably to be well attended to by the sheep-grazier, and turned as much as possible to his own account. See *GRAZING, and STOCKING Land.*

The practices and profits of different sheep-grazing farmers are often very different in the same situations, as scarcely any two farms of this kind are conducted exactly in the same manner for the whole of the same year, or probably the same farms for two succeeding years together; as farmers of this sort must be directed and regulated in their management by times, circumstances, and seasons, so as to have their lands stocked according to the growth, or the probability of the growth, of grass on them; taking care to have them always provided during the early summer months. Peculiar local circumstances, and the difference in the conduct and management of individuals, as well as capita, may also have great influence on the profit. On these grounds, the ordinary profit may amount, in favourable cases, to one pound the acre, and from that to two or three, as they are less or more favourable. The difference of practice which is had recourse to, as it relates to the sorts of sheep-stock, may likewise further increase it.

The employing sheep-stock wholly is probably the most profitable plan of all others, where such stock can be readily and reasonably procured, at all times, in the lean state; but which is not always the case. And where the grazing farmer, as in the Romney-Marsh practice, can either send them readily to the uplands for the winter, or feed them on turnips, and have their lambs well kept, and send out a sufficient number, as well of them as of the tegs or two-years old sheep, or render these last fat, as is sometimes the case, a greater profit, it is said, will be produced than in other ways. The value of the wool is likewise to be taken into consideration in this sort of stock, as it tends to profit.

The profits of the breeding system, in the above marsh, with sheep, depends much upon the qualities and properties of the lands for the purpose, as some will carry and keep a far greater number of them than others; as two to the acre, two and a half, and three on the same extent of ground. It is unquestionable, that by lightly stocking such lands in the winter season, the growth of the summer grass would be greatly benefited; but 100 acres of such breeding pasture land, which keep only 200 sheep, producing 220 lambs, will not pay so well, it is thought, as if 300 ewes were kept, producing 340 lambs. Two returns, therefore, are not capable of being made in the breeding system, as many ewes are, of course, under the necessity of being kept in the winter time as such lands will support. It is, however, suggested, that by the use of hay and artificial food, much increase of profit might not only be produced, but  
such

## SHEEP.

such pastures be improved; which should be the constant aim of the sheep-grazing farmer, whenever the expences will allow of it. Further, the expences of labour and keeping such pasture-lands in proper order, losses of stock, &c. must take greatly away from the profits of this kind of farming. It is, on the whole, thought, that though the profits of the breeding system may fluctuate considerably, it will not be so great as in some other modes of sheep-grazing. The breeding sheep-farmer may, it is said, "have a large or a small crop of lambs; he may lose a great many, or only a few ewes. There may be an increase or decrease in the value of the lambs, old sheep, or wool; there may be a prolific or scanty crop, an increase or decrease of rent; which circumstances cannot fail to alter the profits of a breeding grazier." But that lately, for many years, the great demand for lean sheep and wool has contributed greatly to the profits of farmers of this kind. The profits and advantages of the fattening system of sheep management, which is more varying, will be afterwards particularly considered, and in some measure compared with the breeding practice.

The original differences in the value of lean sheep, for the purposes of the breeding sheep-farmer, and as they may happen to be in a better or more reduced condition, must have a further effect on the profit of this system of management, as often amounting to not less than from three or four to eight or nine shillings the head.

*Fattening-Management of Sheep.*—In the business of fattening store sheep, there are many circumstances that should be carefully attended to, as well as that of managing the breeding and other flocks. The kind of sheep that are most advantageous under the different sorts of keep, situations and kinds of land, must be well considered: the differences in the sorts of food, in regard to the improvement of the sheep; and the most beneficial methods of employing it in different cases; and lastly, the markets. And as the sheep under this treatment should never be suffered to have any sort of want of fresh food, they should never be kept too long upon any inclosure or grafs-piece, or any other sort of keep, so as to be compelled to feed upon the sullied or trampled food, as it always greatly retards the fattening of the animals, or what is termed proof, which is constantly the most promoted by the allowance of only the prime fresh food.

There are many different sorts of food made use of in this business, such as the different sorts of turnips, which are very extensively applied in this system, and some use them alone; but it is probably a better practice to give some sort of dry food with them, especially where the common turnip is employed, as it is more watery and less nutrient than that of the Swedish kind. Cut hay, chaff, bran, corn, oil-cake, all answer well in this intention; and of the first two or three sorts they should have a pretty full supply; but the latter, from their expence, should be more sparingly given; several pounds of oats will however be required for each sheep *per* day, according to the kind and size. It is stated in the Norfolk Agricultural Survey, lately published, that captain Beacher having 700 fattening sheep, and turnips running short, put 200 of them to oats (not ground); he found that the practice would not answer if oats were more than 6s. *per* coomb, and then not for longer than six weeks: they were fed on a pasture, and the improvement of it very great. He thinks grey peas or beans would have answered much better.

With oil-cake, some give half a cake a day to each sheep, but the quantity must depend in some measure upon the other keep which they have. All food of this sort should be given in moveable troughs, divided in the middle, so that the sheep may feed on each side, with a sloping roof over

them, so as to cover the sheep's heads and necks while feeding, as wet is not only prejudicial to the sheep, but spoils the cake. A rack for hay, fixed over the trough, might probably be made to answer in this intention, while it would be very convenient for holding that material, and preventing waste. The whole should be fixed on wheels, and be made to stand steady, and a sufficient number for the quantity of sheep be always in readiness.

Steamed or baked potatoes, cheap convenient contrivances for the preparation of which have been lately invented, have been supposed by some to be preferable to turnips as a food in this intention. And they have been employed raw in the proportion of eight or ten pounds *per* sheep in the course of the day or night; but they are certainly a much better food in their prepared state. The quantity of common turnip consumed by each sheep in the same length of time, is usually about eighteen or twenty pounds. Where this last sort of crop is good, an acre is supposed to support about five score sheep in the field, six or seven weeks in the winter season: an acre of good grafs supporting at the rate of one hundred couples from five days to a week.

In the fattening of widders, the use of barley meal, with grafs or some other sort of green food, has likewise been found highly beneficial, and when it can be procured at a reasonable rate, should not be neglected, as it is quick in rendering them fat, and the mutton is excellent.

Different other articles are occasionally made use of as the fattening food of sheep, such as peas and beans, or pea and bean meal in the winter season, and some substances of other kinds. It is not known that any sort of pure saccharine matter has ever yet been tried in this intention in sheep, but it is probable that it could not fail having the effect in a very expeditious manner, if the expence of it would allow of its application in such a way; and it might be conveniently given, in small quantities at a time, in mixture with chaff, cut hay, bran, or any other similar sort of material, in covered troughs or bins for the purpose, suitable other sorts of food being had recourse to at the same time.

On the most usual sort of food for this use, that of turnips, sheep are very apt to go backward, unless fattened out before the winter season sets in. Indeed the loss from keeping fat sheep through the winter is often so considerable, that it is advisable to have them ready to sell at the close of summer, to prevent the winter keep from being thrown away. The most beneficial application of this sort of food in fattening sheep, has, however, probably not yet been fully shewn, as some kinds of sheep are said to pay well in winter fattening.

In fattening sheep in yards with potatoes, some take them in towards the latter end of the year, and keep them until they are ready for sale about the beginning of March. They have the potatoes sliced, and put into covered sheep-troughs, a gallon being sufficient for a sheep in the day. They mostly prove well on this sort of food, so that if a fair trial be made, the potatoe system will probably be found the most expeditious of any in fattening these animals. When compared with different sorts of grain, oil-cake, &c. by means of accurate trials with sheep in every way the same, it has been proved to be the most ready in effecting the business. A little hay is mostly given with the potatoes, morning and evening. A vast mass of excellent manure is likewise raised by this practice, where due care is bestowed in the preparation of the yard. Many other substances tried in the same way, may possibly be equally beneficial in this intention, though they have not yet been made use of by sheep-farmers.

In regard to the profits of the fattening practice of sheep

## SHEEP.

management on the more rich lands of the marsh kind, they must vary much according to the nature of the methods which are pursued by different sheep-grazing and fattening farmers, as some will make their land carry nearly one-third more stock than others, though the quality of it may be the same, while such stock will do equally well, if not better. Such commonly make the largest profits as have constantly the best supply of additional sheep-stock to succeed such as are taken away, and who regard the number more than the quality of them. The fattening practice may likewise be carried further than is proper and beneficial, by which the profits of the individuals will be lessened, and a loss sustained by the nation at large. The nature of the breeds of this sort of stock will have some influence, as they make a more or less quick return, and as they may come to a more cheap or dear market. The best way in general, is to sell the fat stock of this sort when ready, without waiting, but which is not always the case. Where more returns than one are made in the year, there is commonly the most profit made to the sheep-farmer; and the practical management which is had recourse to in such cases, will have a great effect on the profits, as different rich sheep-fattening districts have many different practices, which are more or less profitable, as that of stocking the land with sheep, at the rate of three to the acre, from the beginning of one autumn to that of another, and having recourse to mixed stock of other sorts during the summer for producing the profits: that of stocking with barren ewes which have had lambs, at the same time, but only at the rate of two to the acre, so that the keep may render them in a great measure fat by the beginning of the new year, and they may be fold off in March or the following month, in their wool, so as that the advance in their price may more than compensate for having it, by keeping them on until May. And after these are gone, by again stocking the same land with sheep brought in from the markets, fairs, hills, or neighbouring high grounds, or the two-years old wethers that have been kept out, or, which is perhaps the best stock in these cases, with such tegs as have been well kept through the winter, and which are equal in weight with starved or stunted two-yearlings. This is a most profitable sheep-fattening system, where it can be carried into practice, that of putting, what are denominated made barrens, or such ewes as have missed going to lamb, upon the fattening land; but as these will not form the necessary supply of stock, other sheep or mixed stock must be provided to produce sufficient profit. It is never a good practice to turn poor lean sheep directly upon the rich fattening lands, but to keep them some time on the inferior pastures, as they are in danger of becoming diseased by the former method. But half-fat sheep may be put immediately upon them without danger, and be fed out, often in the course of two months or less, by which the sheep-grazing farmer is enabled to have another return, which may contribute greatly to his profits.

In the sheep-fattening system, it is often of advantage to have a portion of land, of a superior rich quality, for the purpose of finishing them out upon; as by such means not only more sheep can be fed out and returned, than if the regular quantity of stock was kept upon the different fields, but the less rich pastures be stocked in a more close manner, and as the more quick feeding sheep advance, be taken into the rich finishing portion.

There are several other circumstances which have much effect in this system of sheep management; but the profits will materially depend on the proportion, the richness, and the quality of the farmer's fattening to his other lands, and the judgment which he possesses in the buying in lean stock,

the nature of the season, the state of the markets, the losses sustained, the expences of the management, &c. as already seen.

Though the size of sheep is by no means a point of much consequence in the breeding practice, it should not on any account be overlooked in that of fattening.

The average profit of middling-sized fat rich pasture sheep may be stated to be from about one pound to one pound four or five, or even ten shillings, or even more in some cases.

*Folding-Management of Sheep.*—In the management of sheep there is a practice made use of in some districts, which remains to be noticed; and which is that of folding. It was formerly thought to be indispensably necessary to the success of the farmer in different districts; but of late a different opinion has prevailed, except in particular cases, and it is considered as merely enriching one field at the expence of another. The practice may, however, be beneficial where there are downs, heaths, or commons. The ideas of farmers are not, however, uniform on this subject, as will be shewn by the following details from the Norfolk or Hertfordshire Reports on the agriculture of these districts. In the former it is remarked, that near Brandon there is a practice, introduced about ten years ago, said to be from Kent, which is, to fold their flocks for five or six hours in the middle of the day in hot weather. And that, in laying out the inclosures of the farm at Waterden, from fifteen to fifty acres each, much attention was paid in the arrangement to have every field of the farm to open into a lane, that leads through the whole, so that by dividing the flock for stocking, according to varying circumstances, Mr. Hill can keep at least one-fourth more than when all the breeding ewes and lambs were in one flock, and the food dirtied by driving to fold: by this means there is not a bent on the farm, the stocking being equal. He is not, however, entirely without a fold: when the lambs are weaned (usually about old Midsummer) the ewes are folded for about two months, principally to prevent their breaking pasture, when the lambs are taken from them: and while thus folded, he finds that it takes one-half more land to feed them than if they were left allotted, as through the rest of the year. That folding lessens the value of the lambs he has not a doubt, and that considerably; they do not bring so high a price as others not folded. This is not opinion, but fact. The ewes are also in doubly better condition, from lying still and quiet. That the *teath* will, in certain cases, be unequally given, he does not deny; but it is not difficult to remedy this by the dung-cart; to fold a lot in its own lay, is also a remedy, and is the only sort of folding he can approve. In regard to the effect on wool, he is clearly of opinion that folding does not render it finer, it makes the fleece lighter, but never finer. And folding is generally given up by all who have South Downs; not because they will not bear it, for they bear it better than any sheep in the island; but because the stock is so valuable that it is worth the farmer's attention to contrive, by every means, to keep as many as possible. And it is added, that one circumstance, though a small one, deserves mentioning, for the use of those who form separating sheep-pens: which is, that Mr. Hill has sliding-gates from one to the other; the writer remarked that when a pen is full of sheep, the gates cannot be opened with convenience; but by their sliding in the fence, this is avoided in a very easy manner.

Further, Mr. England, of Binham, does not fold. When not folded, he thinks, sheep do with less food; and as to the common objection, of their drawing under hedges for shelter, in storms, &c. so much the better; it is what they ought

## SHEEP.

not to be prevented from doing. The *tatbe* is much more than lost in mutton. And Mr. Reeve, of Wighton, never folds: folding from layers, upon fallow, is only robbing one field to enrich another. He is clear in this point; and also in the fact, that if sheep (whatever the breed) are driven by foul weather to a hedge, there is the proper place for them, and not by penning left to abide the beating of the storm. Mr. H. Blythe, of Burnham, sometimes folds, but never from choice, but solely by reason of the openness of his farm; nor does he approve the practice. And he explained a point in his manuring for wheat, which, the writer says, comes home to the question: he never sows tempered land with wheat, without either oil-cake, or muck, except on pieces from which the sheep were not folded while feeding the layers. And Mr. Durfgate remarks, that folded sheep certainly demand more food than those which are not folded; a quarter of a ton of rape-cake is equal to the fold; and the flock, without any doubt, suffers more than that value by folding. In short, folding is to gain one shilling in manure, by the loss of two in flesh. Some, however, fold with large flocks. But Mr. Beck, of Rising, does not fold; and he is very certain that if he did fold, he could not keep any thing like the number of his present flock. It is added, that as the writer rode across a layer of forty or fifty acres, on Mr. Overman's farm, he observed a great difference in the verdure, to a line across it, the appearance of one side of that line being so much superior to the other; and on his remarking it, he was informed, that it was an accidental experiment, which was well worth attention: there was no other difference in the management, to make one part of that layer better than another, except the sheep that fed it being from one part of it folded on another arable field during the summer; but from the other part they were not folded at all, but left in the layer night and day. The difference was very considerable, and might have been discerned half a mile off. This experiment made that farmer give up folding, except when his flock was in a salt-marsh; and Mr. Tuttle, a neighbour, asserted, he would never fold at all had he no marshes. Nor does Mr. Etheridge, of Stanhow, fold. These facts should, the writer says, be combined with another, that of heaths and sheep-walks that have been fed with sheep for centuries; but those sheep constantly folded on other lands, are so far from improving them, that they are to all appearance as poor as they could have been at any former period. It is further stated, that Mr. Styleman, at Snettisham, turned his flock loose, and without folding, in twenty acres of *allond* every night, for the same period that would have folded it in the common manner. The sheep did much better than they would have done had they been folded; the face of the herbage materially improved during the period, and upon ploughing it up for wheat the crop was equal to what it would have been with folding, and shewed by a regular verdure, that they had distributed the manure equally in every part. He conceives that lambs sell 3s. a-head lower on account of folding, than they would do without it; but this is only his opinion. He thinks also that the ewe is much injured.

But Mr. Pitts, of Thorpe Abbots, finds that no mucking, on his burning gravels, will do so much good as the fold, and especially on a white clover and trefoil layer for barley. And in the clay district of the county of Hertford, Mr. Byde remarks that sheep have been too much lessened. Of all the common manures, he considers the fold as the best; and he has observed in many farms the general appearance of the crops decline, as the number of the sheep kept has lessened. That at the Hadham's, every man folds the sheep which he keeps; a little farmer will even set four

hurdles, if he has not sheep for more. But that good as the manure of the fold is, Mr. Chapman has found by trial in the same field, for turnips, that yard-dung was much better than both fold and malt-dust together. However, Mr. Roberts, of King's Walden, thinks nothing is equal to the fold; he never reckoned it worth less than 40s. *per* acre, corn being cheap; but of late much more; he folds two poles of ground with twenty sheep. And Mr. Sedgwick, of Rickmanworth, is clearly in favour of folding on all farms. See *FOLDING of Sheep*.

It has been observed by Mr. Ellman, in the *Annals of Agriculture*, that just twenty South Down sheep (if a large fort, a less number will do) will fold one rood *per* night: three thousand two hundred will fold one English acre *per* night. We value the manure at from 35s. to 50s. *per* acre, the goodness of which depends much on the manner in which the sheep are kept; if kept on artificial food, such as tares, rape, clover, turnips, &c. they will drop more soil than if fed on grafs only. Suppose we estimate the folding at 40s. *per* acre, it will amount *per* year to 4s. 6 $\frac{3}{4}$ d. *per* sheep; 22l. 16s. 3d. *per* hundred; or 223l. 2s. 6d. *per* thousand, supposing the sheep folded throughout the year. If it be a breeding flock, it might be well to omit folding for five or six weeks immediately after lambing, as the young lambs might suffer from being trampled upon, and from driving to and from fold, would often lose their dams, and suffer in that way more than if they remained quiet. There is, however, another method of folding, by which all the advantages may be attained during winter on all soils, without the inconveniences of the former plan. This is stated to be by confining them at night in a sheep-yard, well and regularly littered with straw, stubble, or fern; by which means you keep your flock warm and healthy in bad seasons, and, at the same time, obtain a surprising quantity of dung, so great a quantity, if you have plenty of litter, that the profit will be better than folding on the land. A great improvement in this method would be giving the sheep all their food (except their pasture) in such yard, *viz.* hay and turnips, for which purpose they may be brought up, not only at night but also at noon, to be baited; but if their pasture be at a distance, they should then, instead of baiting at noon, come to the yard earlier in the evening, and go out later in the morning. This is a practice which cannot be too much recommended; for so warm a lodging is a great matter to young lambs, and will tend much to forward their growth; the sheep will also be kept in good health, and, what is a point of consequence to all farms, the quantity of dung raised will be very great. If this method is pursued through the months of December, January, February, March, and April, with plenty of litter, a hundred sheep will make a dunghill of, at least, sixty loads of excellent stuff, which will amply manure two acres of land, whereas one hundred sheep folded (supposing the grafs dry enough) will not in that time equally manure one acre.

And in Norfolk, Mr. Bevan finds a yard well fenced in for standing fold for littering and for folding in bad weather convenient; and is fully convinced of the great advantage of it. He intends in future to have his flock in it for yeanning, whether the season be good or bad. And in Hertfordshire, the earl of Clarendon has a fold which contains good room for three hundred sheep, the number kept in it: an open shed surrounds it, except on one side, where a barn is the fence; the outside of the shed is formed of wattled hurdle-work, without straw or other materials, for coolness, lest a greater closeness should make the yard too hot: it is all kept well littered with stubble, and yields, from three hundred sheep, eighty large cart-loads of manure. This system agrees perfectly well with the sheep, and keeps

## SHEEP.

them more healthy than when they were left in the fields in the common manner. His lordship has another yard for lambing, which has also a shed. These sorts of yards, from their beneficial tendency in different views, should be more generally made use of by sheep-farmers in all situations. See *SHEEP-Houfe*.

This practice is had recourse to on arable land for raising different sorts of crops of the corn and green kind, as well as on grafs-lands. It is supposed by some, that a flock of about five hundred sheep will be sufficient to pen twenty-eight square perches of land each night, which will amount to about fifty acres in the year, where the practice is discontinued two months in the course of that time. The value of this is different in different districts, as from above thirty to more than forty shillings the acre, which for five hundred sheep, would be from 87*l.* to 100*l.* for fifty acres, which, taking the average at 94*l.* for that amount of stock, the annual advantage of the fold may be set at 3*s.* 9*d.* a-head, or rather more; taking it at 100*l.* it would be 4*s.* 2½*d.*, or rather more. This shews the great utility of it in some places. All sorts of sheep, except the fattening ones, and those disposed to that state, are mostly folded. It forms a sort of moving dunghill, which enriches the land at but little expence, and which may probably be rendered further useful by a greater division of the flocks. It is also beneficial in preventing the waste of food on grafs-lands, as well as in consuming particular sorts of crops. See *SHEEP-Fold*.

*Hurdling-Management of Sheep.*—It may be noticed, that the great utility of hurdling off different kinds of green crops, in consuming them by sheep, has been long known and practised; and equal advantage may be derived in many cases, by having recourse to the same method on rich grafs-lands in large inclosures, so as to let the animals have a fresh space or bite every day. The sheep are found to thrive better, and the same extent of land to support considerably more in number, while the land is at the same time much improved. And it is not improbable, but that other sorts of stock may be managed in the same way with similar advantage. In these cases the hurdles must be set according to the nature of the grafs; where it is bare and thin, larger pieces should be folded, than in the contrary circumstance. See *HURDLES*.

*Washing-Management of Sheep.*—From the fleeces of sheep becoming much loaded and filled with dust and dirt of various kinds, in the hot summer season, by way of preparation for shearing, it is necessary to have recourse to the operation of *washing*. It was formerly the method of performing this business to have the washers standing up to the breast in the water; but from the inconvenience and danger of it, the men requiring a large supply of spirituous liquors, and being liable to be attacked with colds, rheumatism, and other diseases, as well as being apt to dispatch the work with too much expedition, so as to leave the wool insufficiently clean; it has been proposed by Mr. Young, in his Calendar, to rail off a portion of the water (in a stream or pond) for the sheep to walk into by a slope mouth at one end, with a depth sufficient at one part for them to swim; and to pave the whole: the breadth need not be more than six or seven feet; at one spot to let in on each side of this passage, where the depth is just sufficient for the water to flow over the sheep's back, a cask either fixed or leaved, for a man to stand in dry; the sheep being in the water between them, they are washed in perfection, and pushing them on, they swim through the deep part, and walk out at the other mouth, where a clean pen, or a very clean dry pasture, is to receive them; of course there is a bridge rail-way to the tubs, and a pen at the first mouth of the water, whence the sheep are turned into it,

where they may be foaking a few minutes before being driven to the washers. But other more cheap contrivances may be provided where there is clean water at hand for the purposes. And sheep should on no account be driven on dry or dusty roads after this operation.

But in all cases before this work commences, the lambs should be separated from the ewes and other sheep, and each be put in separate pens. With these it is seldom necessary to do much more than just swirl them through the water, without their being touched by the washers. As soon as they have been washed, the sheep should have a clean hard pasture for a few days, until they are perfectly dry, and in a proper condition to be shorn. The lambs are generally shorn, especially in the northern districts, a few weeks after the old sheep, and the operation is termed *shearling*. The lambs that are sold in Smithfield market are, we believe, seldom or ever shorn. See *SHEEP-Shearing*, and *SHEARLING of Lambs*.

The practice of washing the sheep before they are shorn is a custom that prevails over most part of the kingdom, especially with the long-woolled breeds, and pretty generally with those of the short-woolled kinds also, but which is performed with more difficulty in them from the close-matted nature of the fleece. It is said, however, to have been the custom in Devonshire, for a great length of time, never to wash the short-woolled sheep, but to shear them dry, as is constantly the case in Spain.

The practice of washing the sheep before shearing now, however, begins to prevail in some parts of it, according to the writer of the Agricultural Report of the county. This has at length been enforced, it is supposed, by the difference in the price which the wool-buyers make between wool in the yolk and washed wool, which is no less than 50 per cent. even in the Dorset sort of wool; and though it is not so much, it is greatly more than proportionate in the coarser fleeces, besides the over-weight of 5 per cent. The wool of the Dorset fat wether sheep, which is about five pounds each when washed in the yolk, rarely sells for more than 1*s.* the pound, but when washed, it as commonly commands 1*s.* 6*d.* The weight of a fleece in the yolk, is to the same fleece when washed, it is said, as six and three quarters to five, and the consequent value is as 6*s.* 9*d.* to 7*s.* 0*d.* the fleece. This has, at length, been made evident to the sheep-farmers of this district, who now willingly agree, that it is advantageous to wash short-woolled sheep before shearing, but to sell the long and coarse stapled fleeces in the yolk.

Good clean washing is a matter of great consequence to the wool; and it is of much advantage to it as well as the sheep to have the weather fair and fine at the time it is performed, as they are much less liable to have colds.

*Shearing-Time.*—In respect to the proper period of clipping or shearing sheep, it must be directed by the state of the weather, and the climate in the particular district; and by this means the danger of injury by cold, from depriving the sheep of their coats at too early a season, and from heat, by permitting them to continue on them too long, may be avoided in the best manner. But another circumstance, that should likewise be attended to in this business, is that of the wool being fully grown, or at the state of maturity; as where the clipping precedes that period, it is said, in the Annals of Agriculture, to be weak, and scarcely capable of being spun; and if protracted later, it is yellow, felted, and of an imperfect nature. It has been stated, that for the more warm sheltered situations in the southern parts of the kingdom, the beginning or middle of June, when the weather is fine, may be in general the most proper; but in the more exposed districts, in the northern

## SHEEP.

parts of the island, the middle or latter end of the same month may be more suitable, provided the season be favourable. But with the fattening sheep in the inclosures, it will mostly be necessary to perform the work at an earlier period, in every situation; as the great increase of heat, from the setting in of the summer weather, added to the warmth of the fleece, becomes very oppressive and injurious to them, in their feeding and other properties.

It is an excellent practice with many good sheep-farmers, to clip off all the coarse soiled wool about the thighs and docks, some weeks before the usual time of washing and clipping the sheep; as by this means the sheep are kept clean and cool, when the season is hot, and with ewes the udders are prevented from becoming sore. This practice is common with some South Down sheep-masters, as well as in Yorkshire. In the former situation, Mr. Ellman tells his, as locks, at  $3\frac{1}{2}d.$  per pound, having about four ounces from each sheep.

By some it has been proposed to shear sheep two or three times in the course of the year, with the view of having finer, as well as a larger quantity of wool; but it is probable that such a practice can never be of any general advantage, though the trials that have been made in Northumberland in this way seem to show that advantages may be derived in both these intentions; but the disadvantages in respect to the sheep do not seem to have been sufficiently attended to. And with the same view, the clothing of sheep has been had recourse to. In experiments made in this way in Scotland, the advantage in respect to wool is stated to have been very considerable, and the expence not more than  $7d.$  per sheep. By having recourse to this practice with that of the above, it has been suggested that combing wool may be rendered fit for the purpose of clothing, and at the same time the mutton rendered more valuable. The trials in these ways have, however, hitherto been but few, and do not seem to extend.

It may also be noticed, that in the general management of sheep, it is usual, after the shearing has been performed, to mark the sheep with redde, ochre, or some similar substance; and some also cut the ear in different ways. The marking with tar has been said to be prejudicial; but where a small quantity is only employed, little injury can be sustained. And in almost all the sheep districts of the kingdom, except in Dorsetshire, the tails of sheep are shortened, which seems to be an useful practice in keeping the animals more clean behind, and of course less liable to be stricken with the fly. It has, however, been suggested in the ninth volume of Annals of Agriculture, that by this custom the sheep may be rendered less able to drive away the flies. The general prevalence of the practice would, however, seem to prove its being of advantage. There is much difference in the manner of performing the business in different districts, in respect to the length; but four or five inches being left, are quite sufficient. It is usually done while the animals are young. In all sheep-pastures the hedges should be well cleared from briars, as their coats are often injured by being torn by them; and all sorts of pernicious reptiles should be as much as possible destroyed, and removed from such land.

Further, in respect to the business of castrating or gelding the lambs, it may be performed any time from the age of a fortnight or three weeks to that of a month or six weeks; and in some districts it is deferred to a considerably later period. It is, however, the safest method to have it executed early, as there is less danger of too much inflammation taking place. But in all cases, the lambs should be in a healthy state, when it is done; as under other circumstances, they

are liable to be destroyed by it. The operation is usually performed by the shepherd, by opening the scrotum or cod, and drawing out the testicles, with the spermatic cord. This he often does with his teeth, in the young state of the animal. But where the operation is performed at a later period, it is usual to have recourse to the knife; the arteries being taken up, and secured by means of ligatures or the searing-iron. The business, if possible, should be done in fine weather, when not too warm; and the gelded lambs be kept in a dry, sheltered, quiet situation, for a few days, until the inflammation is gone off. If it should happen to be wet at the time, it may be advisable to have them under some sort of shelter, where they can have room to move freely about.

It is now well known that the mode of ascertaining the age of these animals is chiefly by their teeth; but they are likewise sometimes named from the number of coats or fleeces that have been shorn from them, as one-shear, two-shear, &c. The sheep of one-shear having two broad teeth before; that of two-shear, four; that of three, six; and that of four, eight; which is full-mouthed. See AGE of Sheep.

And they have also different names in different districts. After being weaned, the ram or wedder-lamb is sometimes termed *hog*, *hoggit*, *teg* or *tag*, during the whole of the first year; and the female lamb, an *ewe* or *gimmer-lamb*, and *ewe-teg*. The second year, the wedder has the title of *shear-hog*, or a *two-toothed teg* or *tag*; and the ewe is called a *thaiwe*, *thawe*, or *two-toothed ewe*. In the third year, a *shear-hog*, or *four-toothed wedder*; and a *four-toothed ewe*, or *thaiwe*. The fourth year, a *six-toothed wedder*, or *ewe*. And in some places, from the time of lambing till that of salving, the males are called *tup-lambs*; and from that period till the time of shearing, *tup hogs*; and ever afterwards, *tups*; the females in the same order being termed *ewe-lambs*, *ewe-hogs*, *gimmers*, *young ewes*, *old ewes*. The gelded male lambs, *castrated wedder-lambs*, *wedder-hogs*, *dummonds*, or *dimmonts*, *wedders*. *Crones* also signify old ewes; and there are several other provincial names, which are explained in their proper places, under their different heads. See SHEEP, Names of.

In the management of this sort of stock, it must be sufficiently evident that a great deal of the profit and advantage must depend upon having a careful attentive shepherd, who perfectly understands his business, and is at all times willing to perform it. See SHEPHERD.

Sheep are subject to a variety of diseases, which should be carefully attended to by those who have the care of such sort of stock, as soon as ever they shew themselves; as a very short time often renders them irremediable. The nature of them, and the means of removal, are described under the proper heads to which they belong.

The above accounts, observations, and details, may serve to afford the inquirer a general knowledge of the nature of sheep husbandry, and of the usual methods of management which are required with that sort of live-stock, as well as the benefits and advantages which may be derived from it in many different ways.

SHEEP, and their Varieties, chiefly in connection with the Woollen Manufacture, History of. Of all the animals that have been domesticated by man, none have rendered him more essential service than the sheep. A large part of the food and clothing of the civilized world is supplied by this useful animal. The culture, improvement, and manufacture of its fleece, have constantly accompanied and marked the progress of civilization, both in ancient and modern times.

## SHEEP.

In the early ages of society, sheep appear to have been principally domesticated for the sake of the skin, or the fleece: we shall, therefore, first take a short view of their cultivation and improvement in different countries, as wool-bearing animals; whether as producing fine or coarse wool, or as *long* or *short-woolled* sheep; the produce of the two latter differing from each other in the mode of manufacture, and the uses to which it is applied, more than silk and cotton, considered as articles of manufacture.

It is not a little remarkable, that the domesticated sheep depends for its subsistence almost entirely on the care of man, and is never found at any great distance from his habitation. "Left to itself, it becomes the subject of disease, and the prey of ferocious animals; or if these should spare it, its own fleece becomes the abode of insects, which continually nourish themselves with its blood, and destroy its constitution. Its enemies are indeed so numerous, and constantly at hand, that it has no chance of escaping them."

Naturalists are not fully agreed from what animal the different varieties of domestic sheep originally sprung. The Siberian argali, as described by Pallas, was most probably the parent of all the cultivated flocks in Asia, from whence they have spread to other parts of the world. This animal, the argali, which in the Siberian language means wild sheep, is called by the Russians *kamenoj barann*, or sheep of the rocks, from its ordinary place of abode. According to Pallas, it is the same with the musimon of Pliny, and the ophion of the Greeks. It is found, in all its native wildness, vigour, and activity, inhabiting the vast chain of mountains which run through the centre of Asia to the Eastern sea, and the various branches of this chain, extending through Great Tartary, China, the north of Hindoostan, and Persia. The argali delights to bask in the sun on the bare rocks, but avoids the woods and shade; it feeds on alpine plants and shrubs; it prefers a temperate climate, but is found also amongst the rocks of Asiatic Siberia. This animal loves a state of solitude, and flees the haunts of men. According to professor Pallas, nothing but the surrounding sea can account for the argali being found on an inhabited island, as is sometimes the case.

The ewe of the argali brings forth before the melting of the snow: the lamb resembles a young kid, except that it has a flat protuberance in place of horns, and is covered with dark grey hair, frizzled and woolly.

There are few animals more difficult to overtake than the argali. When pursued, it turns and doubles like a hare, scrambling over the rocks with wonderful agility. Though the adult animal is untameable, the lamb is easily domesticated, when taken young, and fed on milk, and afterwards on fodder, which is proved by numerous experiments made in the Russian settlements.

The argali is about the size of the fallow deer, but its make is more robust, being less elegant than the deer, and its neck and legs are shorter. Its head resembles that of a ram, with long straggling hairs about the mouth, but no beard like the goat. The horns, according to the drawing given by Pallas, bear a similarity to those of the Merino rams; their weight is about sixteen pounds; the tail is short. The summer covering of the argali is a short sleek hair, resembling that of the deer; the winter coat consists of wool, like down, generally of a white colour, and intermixed with longer hair. See ARGALI.

From the facility with which the young of the argali is domesticated, and from the character of this animal, as well as its situation, we may with much probability infer that it was the parent of the Asiatic flocks. According to other travellers, the coat of the argali is of a grey or nut-brown

colour: probably it may be of different colours in the different districts it inhabits. In early ages the fleeces of domestic sheep appear to have been all of a dark colour: such was the flock of Laban, in Mesopotamia; and the narrative of the manner in which the change was effected, may serve to shew that, previously to that time, the common colour of the sheep was black or dark-brown. The improvement in the quality, as well as the colour of the fleece, has always been closely connected with the progress of the arts; for we uniformly find in countries, where these have flourished, a race of sheep which yield wool of a superior quality to those around them. In Persia and Syria, the influence of ancient manufactures is still visible in the superiority of their sheep, as fine-woolled animals. From Asia Minor these animals were transported into Greece, and from thence into Italy and Sicily. They were dispersed by the Romans over various parts of Europe; and the Tarentine sheep, formerly celebrated for their fine soft wool, were introduced into Spain, where they have flourished for sixteen centuries; the present Merino race being their immediate descendants, but rendered more hardy by an intermixture with the original native sheep of Spain.

From the writings of Columella, and the incidental circumstances mentioned by ancient historians, we may infer that the fine flocks of Greece and Italy were of the short-woolled kind, producing clothing wool, which was manufactured into woollen cloth, similar to what is at present worn; but probably more flexible, from not undergoing so completely the milling or felting process. (See WOOL.) Indeed, from the remains of the Tarentine flocks at present in Italy, we can be at no loss to determine the nature of the former Tarentine fleece. Thirteen centuries of neglected cultivation, and intermixture with other breeds, have not been sufficient to obliterate the labours of former times. From what we have seen of the finer Italian wools; we have no hesitation in asserting, that by judicious and careful selection, it would be practicable to restore the Tarentine race once more to its original purity, in the course of a few years; were it found to possess any superior merit, compared with the fine-woolled sheep of Spain. The circumstances respecting the management of the Tarentine flocks, recorded by ancient writers, when compared with the present treatment of the Merino flocks in Spain, leave no doubt respecting the origin of the latter.

The term Merino, in the Spanish language, is an adjective; derived from the corrupt Latin *merinus*, or *majorinus*: when united with *ovejás*, it signifies the royal judge, or superintendent of the sheep-walk. At the period when the *trashumantes*, or travelling flocks in Spain, were established, they became the objects of police, and were placed under the exclusive jurisdiction of mayors, with public walks and large districts allotted for their sustenance, and were termed *Merinos ovejás*, or the sheep under the care of the merino or mayor. The names peculiar to the establishment of these flocks, such as *mesla*, *cavana*, &c. are derived, not from the Morisco, but from the provincial Latin that prevailed in Spain before and after it was subdued by the Goths. (See MESTA.) The management of the flocks is peculiarly Roman; the merino, or mayor, corresponds exactly with the *magister pecoris* of Varro and Columella, and was superior to the *opiliones* and *pastores*. The practice of destroying half the sheep at their birth, and of sucking each of the survivors on two ewes; of sweating the sheep before they were shorn, to increase the softness of the fleece; and of conducting them from their winter to their summer stations, by long journeys through public sheep-walks, has been derived from Roman institutions, with this difference, that in Italy their migrations were

## SHEEP.

were confined to the coarse-woolled sheep, while the *molles oves*, or fine-woolled flocks of antiquity, were always housed.

The experiment of Columella's uncle ascertains the early introduction of fine-woolled sheep into Spain. Having procured some wild African rams at Cadiz of a coarse fleece, but of an admirable colour, he gave them to some fine-woolled ewes, and the male progeny being again given to Tarentine ewes, the offspring, with their descendants, united the paternal colour with the peculiar softness of the maternal fleece. Columella's uncle resided in Bœtica, which comprehended the modern Estramadura; and as Columella flourished under the emperor Claudius, the Tarentine breed must have been introduced into that province at the commencement of the Christian era. Whatever was the peculiar colour which the elder Columella introduced by means of African rams into his Tarentine flock, we may conclude that the same successful expedient was employed by other agriculturalists of Bœtica, to convert these coarse into fine-woolled breeds, and to communicate the purest white to the black or parti-coloured native flocks, which, according to Pliny, were common in Spain. The original intermixture of distinct breeds of native Spanish sheep with the Tarentine in different parts of Spain, may be inferred from other circumstances: each *cavana*, or flock, forms a distinct breed; and the Nigrette no more resembles the Paulac, than the Merino South Down resembles the Merino Cheviot. The genuine unmixed descendants of the Tarentine breed would have preferred one uniform character; but the native flocks crossed with Tarentine rams would retain their distinctive varieties, and transmit them to each *cavana*.

That the Merino is a mixed race, seems to be further indicated by the more tender constitutions of the fine-woolled flocks of antiquity. Of these, the Tarentine were most celebrated in Italy, and the Milesian in Asia Minor. They were termed *pellitæ* and *testæ oves*, from the coverings of skin with which they were clothed to defend the fleece. They were denominated also *molles oves*, not only from the softness of the fleece, but from the delicacy of the constitution. They were always fed in the house; and though satisfied with brambles, or the coarsest food, they are described as a most voracious breed: a diminution of their allowance from the fraud of servants, or the parsimony of the owner, was attended with certain destruction to the flock. (Plin. lib. viii. cap. 47.) As there was no sale for the lambs, nor any profit from the milk of a Tarentine flock, half the lambs were destroyed at the birth. The ram-lambs were chiefly reared, and were killed at two years, when their pelts sold to the merchant at an advanced price, on account of the beauty of the pile. This breed demanded constant care, when in the fields, to preserve their coverings from being torn, and the fleeces destroyed. At home they required even greater care than abroad, as they were not daily conducted to their pastures. They were frequently uncovered and cooled for refreshment. The staples of the fleece were opened and disparted, and were frequently moistened with wine and oil. The whole flock was washed three times a-year, when the weather was warm. The stables were frequently swept, cleaned, and fumigated: for these different offices two shepherds were constantly required for every hundred sheep.

The excessive care bestowed on these flocks by the nations of antiquity, shews in what estimation their fleeces were held; and though such attention is remote from modern practice, we are fully convinced that, by selecting the very finest and softest Merino flocks, and covering the wool, and frequently anointing and washing, it would give to the

pile that degree of softness which is so much wanted in the manufacture of shawls, and other costly articles of luxury, but which we seek in vain in the finest fleeces of modern Europe. However expensive such attention might prove, we have no doubt that, on a limited scale, it would well repay the labour of the judicious experimentalist, as the wool would be worth more than 30*s.* per pound, could it be made to equal that of India in softness. It would appear that the Tarentine breed were selected with much care for breeding, and every expedient adopted, which was proved by experience to attenuate and soften the pile. The transition of these delicate animals into the Merinos of Spain, which are a hardy race, can only be explained by supposing that other agriculturalists had imitated Columella, and obtained a fine-woolled race, by crossing their native breeds with the more delicate animals from Italy. The beginning of this improvement is indeed described by Strabo in the reign of Tiberius: he informs us that the inhabitants of Truditania had formerly imported many garments, but that their wool in his time surpassed that of the Coraxi, and excelled it in beauty so much, that a talent, equal to two hundred guineas, was the stated price of a ram to breed from; and that they excelled also in the fabrics which the *Saltiatæ* manufactured. Truditania, according to Strabo, comprehended the province of Bœtica, from the Guadiana to the confines of Lusitania, and southward to Gibraltar, and eastward to Toledo. The wool of the Coraxi, with which Strabo compares that of this part of Spain, we are informed, in his account of Pontus, was from the soft-woolled Milesian sheep. Such high prices as a talent must have been produced by a very general demand for rams, not for the use of the Tarentine flocks, which could occasion no such competition, but for the purpose of crossing the indigenous breeds of the province, which, from the earliest period, appears to have abounded in sheep.

The travelling flocks were not at that time introduced, as the mountainous regions had been till then infested by native as well as Lusitanian robbers, whom the Romans dislodged from their villages, and dispersed into cantons. (Diodorus Siculus, lib. v. cap. 32.) The Moorish looms of Andalusia and Catalonia, and those of the Christians at Segovia, in the 13th century, must have been supplied by the fine-woolled flocks introduced by the Romans. The vacant mountains, when cleared of banditti, offered a vast range of pasture from Estramadura northward, towards Galicia and the Asturias. A similar opportunity occurred to establish or renew the institution of travelling flocks when the Christians descended, in the middle of the 13th century, to occupy the conquered provinces of Andalusia and Murcia. After that time the travelling flocks became so well established, that the *mentargo*, or tolls, on their passage through the mountains, from province to province, the *servicio*, or tax to the crown, and the laws of the *mesta*, were imposed or ratified by government, in the middle of the 15th century, before the Moorish kingdom of Grenada had been finally reduced.

We are thus enabled from history to trace the introduction and establishment of the Merino race of sheep in Spain, from which, or from their descendants, nearly all the manufactories of fine cloth in Europe are at present supplied with wool. See Wool.

The native breeds of Bœtica were originally and gradually converted into fine-woolled animals, by repeated crosses with the Tarentine flocks, and thus an immense number of hardy sheep, producing a most valuable pile, were spread over the country, and furnished the successive conquests of the Goths and Vandals, and the protracted warfare

## SHEEP.

In the early ages of society, sheep appear to have been principally domesticated for the sake of the skin, or the fleece: we shall, therefore, first take a short view of their cultivation and improvement in different countries, as wool-bearing animals; whether as producing fine or coarse wool, or as *long* or *short-woolled* sheep; the produce of the two latter differing from each other in the mode of manufacture, and the uses to which it is applied, more than silk and cotton, considered as articles of manufacture.

It is not a little remarkable, that the domesticated sheep depends for its subsistence almost entirely on the care of man, and is never found at any great distance from his habitation. "Left to itself, it becomes the subject of disease, and the prey of ferocious animals; or if these should spare it, its own fleece becomes the abode of insects, which continually nourish themselves with its blood, and destroy its constitution. Its enemies are indeed so numerous, and constantly at hand, that it has no chance of escaping them."

Naturalists are not fully agreed from what animal the different varieties of domestic sheep originally sprung. The Siberian argali, as described by Pallas, was most probably the parent of all the cultivated flocks in Asia, from whence they have spread to other parts of the world. This animal, the argali, which in the Siberian language means wild sheep, is called by the Russians *kamnoi barann*, or sheep of the rocks, from its ordinary place of abode. According to Pallas, it is the same with the musimon of Pliny, and the ophion of the Greeks. It is found, in all its native wildness, vigour, and activity, inhabiting the vast chain of mountains which run through the centre of Asia to the Eastern sea, and the various branches of this chain, extending through Great Tartary, China, the north of Hindoostan, and Persia. The argali delights to bask in the sun on the bare rocks, but avoids the woods and shade; it feeds on alpine plants and shrubs; it prefers a temperate climate, but is found also amongst the rocks of Asiatic Siberia. This animal loves a state of solitude, and flees the haunts of men. According to professor Pallas, nothing but the surrounding sea can account for the argali being found on an inhabited island, as is sometimes the case.

The ewe of the argali brings forth before the melting of the snow: the lamb resembles a young kid, except that it has a flat protuberance in place of horns, and is covered with dark grey hair, frizzled and woolly.

There are few animals more difficult to overtake than the argali. When pursued, it turns and doubles like a hare, scrambling over the rocks with wonderful agility. Though the adult animal is unmanageable, the lamb is easily domesticated, when taken young, and fed on milk, and afterwards on fodder, which is proved by numerous experiments made in the Russian settlements.

The argali is about the size of the fallow deer, but its make is more robust, being less elegant than the deer, and its neck and legs are shorter. Its head resembles that of a ram, with long straggling hairs about the mouth, but no beard like the goat. The horns, according to the drawing given by Pallas, bear a similarity to those of the Merino rams; their weight is about sixteen pounds; the tail is short. The summer covering of the argali is a short sleek hair, resembling that of the deer; the winter coat consists of wool, like down, generally of a white colour, and intermixed with longer hair. See ARGALI.

From the facility with which the young of the argali is domesticated, and from the character of this animal, as well as its situation, we may with much probability infer that it was the parent of the Asiatic flocks. According to its travellers, the coat of the argali is of a grey or nut-brown

colour: probably it may be of different colours in the different districts it inhabits. In early ages the fleeces of domestic sheep appear to have been all of a dark colour: such was the flock of Laban, in Mesopotamia; and the narrative of the manner in which the change was effected, may serve to shew that, previously to that time, the common colour of the sheep was black or dark-brown. The improvement in the quality, as well as the colour of the fleece, has always been closely connected with the progress of the arts; for we uniformly find in countries, where these have flourished, a race of sheep which yield wool of a superior quality to those around them. In Persia and Syria, the influence of ancient manufactures is still visible in the superiority of their sheep, as fine-woolled animals. From Asia Minor these animals were transported into Greece, and from thence into Italy and Sicily. They were dispersed by the Romans over various parts of Europe; and the Tarentine sheep, formerly celebrated for their fine soft wool, were introduced into Spain, where they have flourished for sixteen centuries; the present Merino race being their immediate descendants, but rendered more hardy by an intermixture with the original native sheep of Spain.

From the writings of Columella, and the incidental circumstances mentioned by ancient historians, we may infer that the fine flocks of Greece and Italy were of the short-woolled kind, producing clothing wool, which was manufactured into woollen cloth, similar to what is at present worn; but probably more flexible, from not undergoing so completely the milling or felting process. (See WOOL.) Indeed, from the remains of the Tarentine flocks at present in Italy, we can be at no loss to determine the nature of the former Tarentine fleece. Thirteen centuries of neglected cultivation, and intermixture with other breeds, have not been sufficient to obliterate the labours of former times. From what we have seen of the finer Italian wools, we have no hesitation in asserting, that by judicious and careful selection, it would be practicable to restore the Tarentine race once more to its original purity, in the course of a few years; were it found to possess any superior merit, compared with the fine-woolled sheep of Spain. The circumstances respecting the management of the Tarentine flocks, recorded by ancient writers, when compared with the present treatment of the Merino flocks in Spain, leave no doubt respecting the origin of the latter.

The term Merino, in the Spanish language, is an adjective, derived from the corrupt Latin *merinus*, or *majorinus*: when united with *ovejas*, it signifies the royal judge, or superintendent of the sheep-walk. At the period when the *trashumantes*, or travelling flocks in Spain, were established, they became the objects of police, and were placed under the exclusive jurisdiction of mayors, with public walks and large districts allotted for their sustenance, and were termed *Merinos ovejas*, or the sheep under the care of the merino or mayor. The names peculiar to the establishment of these flocks, such as *mesta*, *cavana*, &c. are derived, not from the Morisco, but from the provincial Latin that prevailed in Spain before and after it was subdued by the Goths. (See MESTA.) The management of the flocks is peculiarly Roman; the merino, or mayor, corresponds exactly with the *magister pecoris* of Varro and Columella, and was superior to the *opiliones* and *pastores*. The practice of destroying half the sheep at their birth, and of sucking each of the survivors on two ewes; of sweating the sheep before they were shorn, to increase the softness of the fleece; and of conducting them from their winter to their summer stations, by long journeys through public sheep-walks, has been derived from Roman institutions, with this difference, that in Italy their migrations were

## SHEEP.

were confined to the coarse-woolled sheep, while the *molles oves*, or fine-woolled flocks of antiquity, were always housed.

The experiment of Columella's uncle ascertains the early introduction of fine-woolled sheep into Spain. Having procured some wild African rams at Cadiz of a coarse fleece, but of an admirable colour, he gave them to some fine-woolled ewes, and the male progeny being again given to Tarentine ewes, the offspring, with their descendants, united the paternal colour with the peculiar softness of the maternal fleece. Columella's uncle resided in Bœtica, which comprehended the modern Estramadura; and as Columella flourished under the emperor Claudius, the Tarentine breed must have been introduced into that province at the commencement of the Christian era. Whatever was the peculiar colour which the elder Columella introduced by means of African rams into his Tarentine flock, we may conclude that the same successful expedient was employed by other agriculturalists of Bœtica, to convert these coarse into fine-woolled breeds, and to communicate the purest white to the black or parti-coloured native flocks, which, according to Pliny, were common in Spain. The original intermixture of distinct breeds of native Spanish sheep with the Tarentine in different parts of Spain, may be inferred from other circumstances: each cavana, or flock, forms a distinct breed; and the Nigrette no more resembles the Paulac, than the Merino South Down resembles the Merino Cheviot. The genuine unmixed descendants of the Tarentine breed would have preserved one uniform character; but the native flocks crossed with Tarentine rams would retain their distinctive varieties, and transmit them to each cavana.

That the Merino is a mixed race, seems to be further indicated by the more tender constitutions of the fine-woolled flocks of antiquity. Of these, the Tarentine were most celebrated in Italy, and the Milesian in Asia Minor. They were termed *pellitæ* and *testæ oves*, from the coverings of skin with which they were clothed to defend the fleece. They were denominated also *molles oves*, not only from the softness of the fleece, but from the delicacy of the constitution. They were always fed in the house; and though satisfied with brambles, or the coarsest food, they are described as a most voracious breed: a diminution of their allowance from the fraud of servants, or the parsimony of the owner, was attended with certain destruction to the flock. (Plin. lib. viii. cap. 47.) As there was no sale for the lambs, nor any profit from the milk of a Tarentine flock, half the lambs were destroyed at the birth. The ram-lambs were chiefly reared, and were killed at two years, when their pelts sold to the merchant at an advanced price, on account of the beauty of the pile. This breed demanded constant care, when in the fields, to preserve their coverings from being torn, and the fleeces destroyed. At home they required even greater care than abroad, as they were not daily conducted to their pastures. They were frequently uncovered and cooled for refreshment. The staples of the fleece were opened and disparted, and were frequently moistened with wine and oil. The whole flock was washed three times a-year, when the weather was warm. The stables were frequently swept, cleaned, and fumigated: for these different offices two shepherds were constantly required for every hundred sheep.

The excessive care bestowed on these flocks by the nations of antiquity, shews in what estimation their fleeces were held; and though such attention is remote from modern practice, we are fully convinced that, by selecting the very finest and softest Merino flocks, and covering the wool, and frequently anointing and washing, it would give to the

pile that degree of softness which is so much wanted in the manufacture of shawls, and other costly articles of luxury, but which we seek for in vain in the finest fleeces of modern Europe. However expensive such attention might prove, we have no doubt that, on a limited scale, it would well repay the labour of the judicious experimentalist, as the wool would be worth more than 30s. *per* pound, could it be made to equal that of India in softness. It would appear that the Tarentine breed were selected with much care for breeding, and every expedient adopted, which was proved by experience to attenuate and soften the pile. The transition of these delicate animals into the Merinos of Spain, which are a hardy race, can only be explained by supposing that other agriculturalists had imitated Columella, and obtained a fine-woolled race, by crossing their native breeds with the more delicate animals from Italy. The beginning of this improvement is indeed described by Strabo in the reign of Tiberius: he informs us that the inhabitants of Truditania had formerly imported many garments, but that their wool in his time surpassed that of the Coraxi, and excelled it in beauty so much, that a talent, equal to two hundred guineas, was the stated price of a ram to breed from; and that they excelled also in the fabrics which the Salliatæ manufactured. Truditania, according to Strabo, comprehended the province of Bœtica, from the Guadiana to the confines of Lusitania, and southward to Gibraltar, and eastward to Toledo. The wool of the Coraxi, with which Strabo compares that of this part of Spain, we are informed, in his account of Pontus, was from the soft-woolled Milesian sheep. Such high prices as a talent must have been produced by a very general demand for rams, not for the use of the Tarentine flocks, which could occasion no such competition, but for the purpose of crossing the indigenous breeds of the province, which, from the earliest period, appears to have abounded in sheep.

The travelling flocks were not at that time introduced, as the mountainous regions had been till then infested by native as well as Lusitanian robbers, whom the Romans dislodged from their villages, and dispersed into cantons. (Diodorus Siculus, lib. v. cap. 32.) The Moorish looms of Andalusia and Catalonia, and those of the Christians at Segovia, in the 13th century, must have been supplied by the fine-woolled flocks introduced by the Romans. The vacant mountains, when cleared of banditti, offered a vast range of pasture from Estramadura northward, toward Galicia and the Asturias. A similar opportunity occurred to establish or renew the institution of travelling flocks when the Christians descended, in the middle of the 13th century, to occupy the conquered provinces of Andalusia and Murcia. After that time the travelling flocks became so well established, that the *mentargo*, or tolls, on their passage through the mountains, from province to province, the *servicio*, or tax to the crown, and the laws of the *meita*, were imposed or ratified by government, in the middle of the 15th century, before the Moorish kingdom of Grenada had been finally reduced.

We are thus enabled from history to trace the introduction and establishment of the Merino race of sheep in Spain, from which, or from their descendants, nearly all the manufactories of fine cloth in Europe are at present supplied with wool. See WOOL.

The native breeds of Bœtica were originally and gradually converted into fine-woolled animals, by repeated crosses with the Tarentine flocks, and thus an immense number of hardy sheep, producing a most valuable pile, were spread over the country, and survived the successive conquests of the Goths and Vandals, and the protracted warfare

## SHEEP.

fare of many centuries. The pure Tarentine breed in Greece and Italy being more delicate, is said to have become extinct with the destruction of the Roman empire; but the mixture of this race with the original flocks of Italy may still be distinctly traced, particularly in the middle and southern parts. The Italian wool was finer than that of any other country in Europe, except Spain, prior to the improvements which have recently taken place by the introduction of the Merinos. It is not improbable that the fine-wooled flocks of England, though greatly inferior to the Merinos in the quality of the wool, were also originally descended from crosses with the Tarentine breed introduced by the Romans, when they established a manufacture of woollen cloth at Winehefter.

The destruction or deterioration of the improved flocks in the ages of barbarism which succeeded the fall of the Roman empire, was the natural consequence of the decay of the manufactures, and of a total inattention to prevent the intermixture with coarser breeds. In Spain alone, the improved race had taken such complete possession of the mountainous districts, that it remained unmixed and unimpaired till the revival of commerce and the arts, when that country supplied the neighbouring nations with fine wool, and was supposed to possess some peculiar advantages of soil and climate, which it would be vain to seek for elsewhere. The opinion that the superior fineness of the Spanish fleeces was derived entirely from some peculiarity of the soil and climate, had obtained so generally, and was so firmly believed, even twenty-five years since, in this country, that he who asserted the contrary, was regarded by agriculturalists and clothiers as a speculative theorist, only deserving their pity.

It is not a little remarkable, that this prejudice continued undiminished nearly a century after the Merino sheep had been introduced into Sweden and Saxony, and had continued to produce wool in those countries, equally fine with that of their parent flocks in the Spanish peninsula.

It might have been previously supposed that the climate of Sweden, being much colder than that of Great Britain, and more remote from the annual mean temperature of Spain, would render that country peculiarly unfriendly to the Merino race and to the production of fine wool. This prejudice respecting the influence of climate would have been removed by considering that almost all the finest furs are the production of cold climates, and that the growth of fine wool and fur is a provision of nature, to defend animals against the severe cold of the districts nearer the poles. Mr. Alstroemer, who had previously endeavoured to ameliorate the breed of sheep in Sweden, by importations from England and Germany, obtained a flock of Merinos, which he introduced into that country in the year 1723. In the year 1739, the Swedish government, for the promotion of this race, instituted a school of shepherds, under the direction of Mr. Alstroemer, and public funds were appointed for granting premiums to those who sold rams of the Spanish breed; and from the same period, to 1780, a premium of twenty-five *per cent.* was also granted on the sale of fine wools of a good quality. These premiums were afterwards reduced, and finally discontinued in 1792, being no longer necessary. From exact accounts, it appears that the fine wool sold from 1751 to the year 1790, amounted to 3,402,961 francs.

The quantity of fine wool actually produced was much greater than what had been sold to receive the premium, a considerable part having been consumed in domestic manufactures by the growers and others; and the distance of the public magazines, where the wools were sent to receive the premium, prevented the public returns from including

the real quantity of fine wool grown. In the year 1764, there were in Sweden 65,369 sheep of the pure Merino race, and 23,384 of a mixed breed, producing fine wool. The Swedish Merinos preserve their primitive form; their fleeces are very close, and the wool has not deteriorated in fineness, length, or elasticity; and the sheep produce as great a weight of fleece as in Spain, wherever they are supplied with a sufficient quantity of food. This race, now naturalized in Sweden, are larger and stronger than the Spanish sheep. M. Laysteire examined the flock of M. Schulzenheim, at Gronfoe, in the province of Upland, which had been introduced from Spain 55 years. On comparing the wool with that of other Spanish sheep recently imported, he did not find it inferior either in beauty or fineness. M. Schulzenheim preserved the descendants of sheep which he imported from Spain to the fifth generation, and the comparison of their fleeces proved that they had not in the least degenerated. These facts prove decidedly that the Spanish sheep do not lose the good qualities of their wool by a removal to cold countries. At the same time it must be observed, that those sheep degenerated which had been neglected, or treated in the same wretched manner as the native flocks, by confining them in damp, infected, and dirty stables during a part of the year, and omitting the requisite quantity of food; or pasturing them in summer in forests and marshes, or in low moist situations, where they could neither find the proper kind nor due quantity of herbage.

The introduction of the Merinos into Saxony took place in 1765, and again in the year 1778. The first flock consisted of one hundred rams and two hundred ewes, chosen for the elector of Saxony from the best flocks in Spain; they were placed under the care of a Spanish majorinus, or mayor, at Stolpen, six leagues from Dresden, on the frontiers of Bohemia.

After ten years' experience, it was found that they had preserved all the original good qualities of the fleece, and the wool from the mixed breed had also acquired a degree of fineness which did not yield to that from Spain. As soon as it was ascertained, by experience, that it was easy to naturalize the Spanish sheep in Saxony, and that the crosses from this race with the native flocks were so greatly ameliorated, the attention of the agriculturalists was directed to the general improvement of the flocks, and such has been the success, that their produce is at present one of the greatest sources of profit to the cultivator. During the last fifteen years, a very considerable quantity of fine wool has been imported from Saxony into England, and the price of the best sort is greater than that of the finest Spanish wool, a sufficient proof of the estimation in which it is held by the manufacturers. It is better suited for the finest kerseymeres, and the more delicate articles of the woollen trade, as it can be spun to a greater length than any other kind of carded wool grown in Europe; it is also superior in fineness, but owing to the scarcity of winter food, it is generally less found than the best Spanish, and not so well suited for stout cloths. See WOOL.

The Merino race has since been introduced into Denmark, the Prussian states, Austria, France, Holland, Italy, the Cape of Good Hope, and the United States of America. Of its introduction into England, we shall afterwards speak.

As Saxony is the only country which has yet cultivated the Merinos so extensively, as to come in competition with Spain in the exportation of fine wool, it may be proper to state the modes of treatment adopted in that country. It is generally believed in Saxony, and in other parts of Germany and Holland, that the practice of breeding from the same

## SHEEP.

race, or what the English graziers technically denominate "breeding in and in," occasions a deterioration of the flock; owing to this prejudice, the Swedish farmers frequently change the rams of the Spanish race for others of the same race from neighbouring flocks, and some proprietors bind their farmers to renew a certain quantity of rams every year. But this practice is useless, where the rams upon an estate are already of a good quality; if the contrary were the case, there could not exist a perfect Merino sheep in Spain, as these sheep have continued to breed from the same flock, without any attention to consanguinity, for many centuries. The good quality of a race of sheep may be preserved, either by selecting the most perfect from the same flock to breed from, or by constantly taking out those which are most defective.

The common food of sheep in Saxony, during winter, is hay, which is distributed three times a day, in a greater or less quantity, according to the flock of the farmer: those who have not sufficient hay, substitute pease-straw, vetches, and lentils. They take care to mow the crops before maturity, that they may be more nutritive, and to prevent the fall of the leaves before mowing. Some farmers supply the deficiency of hay with powdered oil-cakes, crushed seeds, and meal; they put the cake or meal into troughs with water, which they give the sheep to drink, and afterwards they give them the solid residue, which sinks to the bottom of the trough. This treatment serves to keep them in a healthy state, at a season when they cannot have fresh food. Eight pounds of cake or meal dissolved in water are given to every hundred sheep. When the snow remains long on the ground, they sometimes give them straw which has not been thrashed, and even corn; but as this is expensive, they generally substitute roots of different kinds, such as beets, turnips, and carrots, but particularly potatoes.

The Saxon farmers collect with great care the horse-chestnuts in autumn, which they give their sheep as a remedy against the rot. The nuts are cut small, to prevent them getting into the throat, and choking the animal.

They send out their sheep in winter, when the weather permits, and the snow is not too deep, to the woods or dry situations sheltered with underwood. Proprietors who have no winter pastures, leave their sheep in the sheep-houses from the beginning of November to April, but they take care to turn them out each day in the fresh air, for three or four hours, and they keep open the doors, to cause a constant ventilation. Some proprietors keep their sheep confined the whole year; and where the sheep-houses are kept clean, and the sheep are supplied with proper food, this practice is not found to injure either the wool or the animal.

During fine weather in summer, they are allowed to range in the pastures. They leave the sheep-house after the dews are entirely dissipated, and they repose in the shade during the heat of the day. This practice of providing shade during the hot weather cannot be too strongly recommended to the cultivators of fine wool in England, both with respect to the health of the animal and the improvement of the wool. Nor is another practice less deserving their attention, which is, to shelter them during heavy rains, hail-storms, and thick fogs. In many sheep-houses, water is conducted in troughs, from which the sheep may drink at pleasure. Saxon farmers consider salt not only as necessary to the health of sheep, but as contributing to the fineness of the fleece; it is sprinkled in their forage, and is dissolved in their drink; it is given principally in summer, when the weather is dry. They cease to give it to the ewes five or six weeks before lambing, because they think that the excess of water which it occasions them

to drink, is injurious to them at that time, and that it also prevents them from licking their lambs.

The rams and ewes are not put together before the age of two or three years: they allow one ram to twenty-five ewes, and leave them together day and night during the season. The lambs are kept in the sheep-houses, but some proprietors allow them to go out with the ewes after eight days.

Before shearing, the sheep are washed in the English manner, but with greater care. First they make them swim through a river or dam; the following day they are again driven through, and plunged in separately, and the fleece pressed with the hands, beginning from the head, and passing on to the extremities of the body; they are again driven through the water in the afternoon. The fleece is suffered to dry during two days, and shorn on the third. Saxony wool, thus washed, is much cleaner than the English, which generally undergoes but one washing. It loses by a further scouring by the manufacturer, about 12 per cent. more than Spanish wool already scoured. English wool loses about 25 per cent. in the hands of the manufacturer.

The general treatment of the Saxon Merino sheep we consider as judicious, but we have frequently noticed that the wool had been somewhat injured by want of sufficient nourishment in winter, which renders it tender. The hay being given in racks, feeds and straws fall into the fleece when the animal is eating, which the English manufacturer finds great difficulty in eradicating; this might be prevented, in a considerable degree, by lowering the racks, so that the food might be level with the head, or somewhat below.

As France is perhaps the most formidable rival which our manufacturers of fine cloths will meet in foreign markets, the progress made in the amelioration of her native flocks becomes an object of interest to the English agriculturalist and clothier. The celebrated minister Colbert first formed the design of improving the breeds of French sheep, by importations from England and Spain. But his intentions were at that time opposed. It was not till the year 1776 that the Spanish breed was introduced into France by M. M. Trudaine, intendant of finances, under the direction of the celebrated naturalist d'Aubenton. The experiments which he made on these sheep, and numerous crosses from them, with seven distinct breeds, which he had on his estate in Auxors, demonstrated to the government that it was easy to introduce and preserve a race of sheep in France, producing superfine wool; and in the year 1786, a selection of 376 rams and ewes, from the finest flocks in Spain, was conducted, under the care of a mayor, to the farm of Rambouillet. They consisted of individuals of extraordinary beauty, superior to any previously introduced into France, but having been chosen from a number of distant flocks, they presented great varieties of shape and size, which have since disappeared by intermixture; and a new race has been formed, differing from any of the primitive flock, but which equals the best of them in form and constitution, and in the fineness, length, softness, elasticity, and quantity of wool.

It is to be observed, that the wool-dealers and manufacturers in France were at first disposed to depreciate the value of the wool; but numerous accurate experiments having proved that the cloths manufactured from it were in every respect equal to those made from the best Spanish wool, these prejudices disappeared, and the republican government, as well as that of the emperor Napoleon, interested themselves in the further introduction of Spanish sheep into France. In the year 1802 it was calculated that there were one million sheep in France, either of pure Merinos, or of an ame-

## SHEEP.

liorated mixed breed. Since that time many large flocks have been imported from Spain, the temporary command which the French obtained of that country having afforded them facilities for their introduction. In the course of a very few years France will, in all probability, produce a sufficient supply of superfine wool for her extensive woollen manufactories.

The experiments which have been made by the introduction of the Merino sheep into the United States of America, the Cape of Good Hope, and New Holland, prove that fine wool may be grown wherever there are intelligent cultivators, and that it is not the gift of a peculiar soil or climate. We are, however, fully convinced, that very elevated temperatures will require greater care to prevent deterioration. The specimens of wool which we have seen from New Holland, appear to have been affected by an arid sandy soil, and by the great heat of the sun, which has in some degree injured the softness of the fleece. Between the tropics, elevated mountains and shade would be essentially requisite to preserve a race of fine-woolled sheep from degenerating.

The advantages which the Merino sheep possess as wool-bearing animals, over the native breeds of English fine-woolled sheep, consist in three important peculiarities; 1st, the wool is much finer; 2dly, it is more regularly fine over the body; and 3dly, it is grown in a larger quantity from the same surface of skin. That the Merino wool is finer than the best English, is proved from this circumstance; the best sorted Spanish wool, or the R wool, as it is called, from the finest flocks, sells at nearly double the price of the best English sorted wool, or what the wool-staplers call the prime and picked lock. Those English fleeces which yield a portion of the best sort, generally contain a larger portion of inferior sorts: sometimes eight sorts will be found in one fleece, and the finest will not constitute one-eighth of the whole. On the contrary, the fleeces of the Merino sheep are so regularly fine over the whole body, as generally to yield from two-thirds to three-fourths of the superfine or R wool. The second sort, called the F wool, is also fine; and with the T wool, or third sort, bears a higher price than the best English wool. The quantity of wool on a Merino sheep is considerably greater than on an English sheep of the same size: this is not owing to the greater length of the wool, but to the animal being more fully clothed over the body and legs; and the wool is also grown closer than on English sheep; that is, there are more filaments on the same surface. A moderate sized well-clothed Merino sheep will yield a fleece which, when brought to the same state of purity as the English wool, will weigh 3lbs. A Ryeland, Norfolk, or South Down sheep of the same size, will produce a fleece only weighing about 2lbs. The value will be nearly as five to two in favour of the Merino fleece. In this state, however, the Merino fleece is not clean, as the wools imported from Spain, which are scoured after they are shorn, and before they are sorted, by which means it is much cleaner than it can be made by washing on the back of the animal. The Merino rams are horned, which is not generally the case with the ewes. The average weight of a fat ram *per* quarter, is about 17lbs. of a ewe, about 11lbs. *per* quarter.

The shape of these animals by no means corresponds with the symmetry of form which an English grazier considers as the criterion of excellence. The legs are rather long, the neck curved, and from the throat there hangs a pendulous skin, or dewlap, which is very offensive to those who are only accustomed to view the improved breeds of English sheep. This appendage is valued in Spain, as indicating a tendency

to produce wool. The colour of the skin beneath the wool, on the back and sides, is of a rose red colour: this is also considered by the Spaniards as a sign of a robust constitution, and an abundant fleece. The only English sheep which have the same coloured skin with the pendulous dewlap, are the Ryeland, which produce also the finest English wool. These circumstances, with the ancient practice of housing the sheep, continued in Herefordshire, where it is called *cotting*, confirm the opinion before advanced, that the Ryeland sheep were descended from the Tarentine race introduced by the Romans into this country.

It is not to be wondered at, that the Merino sheep, which are cultivated in Spain almost exclusively for their wool, and not for their flesh, should present that deformity of shape which at first was particularly offensive to the eye of the English farmer, accustomed to the new Leicester and South Down sheep. There cannot, however, be a doubt that the Merino breed is as susceptible of improvement as the English. Indeed there is a very great diversity of form in the flocks in different parts of Spain; and were the same attention paid to selecting the most perfect to breed from, as has been given in England to the South Down sheep, there is every reason to believe that a new race would be formed, possessing all the good qualities which both the grazier and the manufacturer might require. The South Down sheep, which have been greatly improved, and rendered almost perfect in form, have preserved all the good qualities of the fleece. This alone is sufficient to prove, that there is no necessary connection between deformity of shape, and the fineness of the wool.

The Spanish breed of sheep were first introduced into Great Britain in the year 1787. Some individuals of the black and spotted sheep had indeed been procured, and kept in the parks of noblemen previously, but without any regard to the wool; nor was much interest excited by the flock introduced in 1787. The sheep, however, lived, though treated in the English manner, and the wool had not deteriorated. These facts having proved that the Merino race might be naturalized in England, his majesty George III. obtained from the marquis of Campo Alanzo five rams and thirty-five ewes of the Nigrette race. They were imported in the year 1792, and were for some time at Oatlands, the seat of his royal highness the duke of York. On their arrival they were extremely low in flesh, but they soon began to improve; and the diseases with which they had been affected, were removed by a plentiful supply of food. They left Oatlands greatly advanced in bulk, and with renovated constitutions; and the quantity and quality of the wool were greatly admired.

The prejudices of the manufacturers were not so speedily to be surmounted, as the difficulties attending the naturalization of the Merino sheep. Though the wool was admitted to be equally fine with the best imported wool from Spain, they would not offer a proportionate price, fearing that it might not prove equally good, when manufactured. It ought, however, to be stated, that the condition in which the English Merino wool was offered for sale, either very imperfectly washed, or entirely in the grease, prevented the manufacturer from forming a just comparison with the wools from Spain, which came to this country clean scoured, and regularly sorted; nor could they appreciate the loss it would sustain in scouring, which is not less than from 60 to 70 *per cent*. We are well persuaded that this uncertainty respecting the loss in scouring has, more than any other circumstance, retarded the sale of the English Merino wool, from the year 1792 to the present time. Nor will our

# SHEEP.

our manufacturers ever greatly encourage the growth of this wool, until it be brought to market, either sorted and scoured like the wools from Spain, or in the same state of purity in the fleece as the fine English or Saxon wool. Many manufacturers, who have purchased it, have been greatly disappointed, not in the quality, which was excellent, but in the small quantity which remained after scouring. In consequence of the manufacturers declining to purchase his majesty's wool, it became necessary to have it manufactured on his majesty's account, to demonstrate its fitness for superfine cloths. This was done till the year 1796, when it was resolved to sell the wool at the price which was offered, that the manufacturers might have a fair trial. The clip was sold that year for 2s. per pound, and the following year for 2s. 2d. In the years 1797 and 1798 the wool was sorted in the Spanish manner, and scoured, after having been previously washed on the sheep's back. The following is an account of the produce.

Eighty-nine ewe and wether fleeces washed on } the back - - - - - }	lbs. 295
Loss by subsequent scouring - - - - -	92
Pure wool - - - - -	203

Of which there was Rafinos, 181 lbs. at 4s. 6d.	
Finos, 22 lbs. at 3s. 6d.	
Terceros, 12 lbs. at 2s.	

The prices have, since that time, progressively increased with the price of Spanish wool, and have been nearly equal to that of the best wools from Spain. In the year 1801, the right honourable lord Somerville took a voyage to the peninsula, for the purpose of selecting such sheep as united in the greatest degree the excellence of the fleece with a good carcase. His efforts were in a considerable degree successful, and, as far as related to the fleece, completely so. Since that time, particular political events have increased the facility of procuring Merino sheep from the various Spanish flocks; and the stock of these sheep in England at present is sufficiently great to change, in a few years, the whole race of fine-woolled sheep in Great Britain, were such a change desirable. Many of the native flocks of fine-woolled sheep in England have been considerably diminished in the last forty years, owing to the numerous enclosures of forests and commons, that were formerly only suited to pasture a race of small light sheep; but which, in consequence of improvement, are now capable of maintaining a heavier race of animals; the former requiring a light dry soil, and an ex-

tensive range; and the latter, a rich and more confined pasture. The Ryeland sheep in Herefordshire afford the finest wool in England, of any of our native breeds; but the pure race is nearly extinct. The fleece weighs less than two pounds; but if generally cleared from the flank-locks and skirts before it is wound, in this state it bears the highest price of any English fleeces. It is not a little remarkable, that the practice of cutting or housing the sheep is peculiar to Herefordshire; and it is not improbable but it may have been originally introduced by the Romans, with the race of sheep from which the Ryelands originally sprung. A mixture of the Ryeland sheep is spread over some of the counties adjoining to Herefordshire, but the number is not very considerable. The light sandy soil of Norfolk is pastured by another breed of fine-woolled sheep, which supply a considerable quantity of fine English wool for the Yorkshire market; and it possesses, in an eminent degree, the property of softness, when manufactured, which is wanting in many of our English wools. The original Norfolk breed have black faces and spiral horns, small, long, thin carcases, with long black or grey legs. The fleece weighs from one pound and a half to two pounds. The form of the animal is not such as to recommend it to the grazier, but it has been greatly improved by an intermixture with the South Down breed. Mr. Coke of Holkham, the celebrated agriculturalist of Norfolk, has disposed of his native flocks of that county, from a conviction, founded on long experience, that they are an unprofitable breed. The principal recommendation of this breed was the excellence of their wool; and they might be well suited to the former uncultivated state of the sandy tracks in that district.

Of all the native fine-woolled breeds of England, the South Downs appear to possess, in the most eminent degree, the combined advantage of excellence of form, with a superior quality of the fleece. The average weight of the two-year old wethers is 18 pounds per quarter; the mutton is fine-grained, and of an excellent flavour. The weight of the fleece of the finest kinds is about two pounds on the average. Some of the coarse fleeces exceed three pounds. The South Down breed takes its name from the district on which these sheep were originally cultivated. It is a long range of rather elevated chalk hills, extending from the south-western side of the counties of Kent and Surrey, through Sussex, into Hampshire, consisting of open downs, well suited for sheep-walks.

The animal has no horns; its face and legs are grey; the bones fine, and the form compact. It has indeed been greatly improved of late years, by the particular care of intelligent growers. The lambs are generally dropped from the middle of March to the end of April. If the ewes have been well kept, one-third will be twins. The wethers are fit for the butcher in two years; many graziers fatten them at 18 months. From the South Downs these sheep have been sent to different parts of the kingdom; and in all dry and rather elevated situations they will preserve the excellent qualities of their wool. Indeed, in all situations where the soil is covered by a good close herbage, and the subsoil is not calcareous, the wool will be of a superior quality to what the same animal would produce on the chalky downs of Sussex. Of this we have had decisive proofs. The South Downs, though in many respects well suited to sheep, yet in those parts where the chalk is exposed, or near the surface, the calcareous particles get intermixed with the yolk or natural grease of the fleece, and produce a degree of harshness in the wool, which is very perceptible, when it is manufactured into cloth: it also injures the felt-

## SHEEP.

ing quality of the wool. This is so well known to the Yorkshire manufacturers, that they always avoid the wools grown on chalk soils, when they want a soft thick pile to the cloth. The fine wool from the South Down fleeces is chiefly used for light goods, such as kerseymeres and pelisse cloths, which require very little milling or felting. When the South Down sheep are removed from chalk lands, the wool may be grown remarkably soft, and possesses all the good qualities of the best native English wool.

The action of the soil on the fleece was long known to manufacturers, *viz.* that wools grown on argillaceous soils were softer, and proved better in the process of manufacture, than those on calcareous soils. The cause of this was involved in much obscurity, and generally supposed to be owing to the quality of the herbage on different soils. Mr. Bakewell, of Wakefield, in Yorkshire, in a little tract "On the Influence of Soil and Climate on Wool," proved that the influence of the soil on the fleece arose from the action of the minute particles on the surface of the fibre or staple. "Not only can this action affect the quality, but impart indelibly the colour of the soil to the wool. In part of Gloucestershire the fleece acquires a deep orange colour from the soil. In Hertfordshire, and part of Warwickshire, and in every country having a red soil, the wool is inclined to brownish-red. Wools on chalky soils are distinguished by their whiteness; and in every district in England the action of the soil is evinced, by communicating its own colour to the fleece. The colour thus acquired is as indelibly fixed in the wool as the colouring matter of an artificial dye, nor can its whiteness be perfectly restored by any artificial process hitherto known.

"That the same cause can change the hardness or softness of wool, is proved from the different effects which argillaceous, siliceous, and calcareous soils are invariably found to have on these qualities. This is perhaps no where more clearly shewn than in the northern part of Derbyshire, where the strata are so abruptly broken, that two adjoining farms, separated by a small brook, will not unfrequently be found, the one upon lime-stone, the other on a siliceous grit or sand-stone. The difference of the wool on these two farms, from the same breed of sheep, was so distinctly marked, that the grower always obtained a higher price when grown upon the latter soil. 'My wool is grit-stone, and I expect a better price than my neighbour,' was the language in common use, and the meaning was well understood by the buyer. In the process of separating wool from the skin by the fell-monger, the pelts are steeped some days in lime and water. The softest wools, when thus exposed to the action of lime, lose their distinguishing excellence, and acquire all the hardness of wools grown on lime-stone soils."

To remedy this injurious effect of calcareous soils, Mr. Bakewell recommends the practice of the farmers in Northumberland, and in North Britain, of anointing the skin of the animal with butter, in which a small quantity of tar is melted to give it consistence. In Northumberland this is practised with the fine-woolled sheep on the Cheviots; and the wool from these sheep bears a higher price in Yorkshire, in proportion to its relative fineness, than any other English wool, on account of the superior softness of the cloth made from it. The ointment is also found to defend the animal against flies and sheep-ticks, and to be a preservative against the severity of the weather. The only inconvenience is, that the whiteness of the wool is in some degree affected by it; and it is not suited for white stoved cloth, or for any delicate colours. Could any good and cheap substitute for tar be devised, there cannot be a doubt that the practice would be of great

benefit to the South Down fleeces on their native chalky soils. It is, in fact, similar to what the Romans adopted with the Tarentine breed, which were frequently washed, and the skins anointed with the dregs of olive-oil, mixed with other ingredients. A similar treatment of all English sheep, after being shorn, would be found a most effective remedy against flies and insects when the skin is exposed: it is also proved by experience to be a preservative against the scab.

The South Down breed, so far as relates to the fleece, will admit of considerable improvement in the following particulars. First; it might attain a degree of fineness more nearly approaching that of the Merino fleece: secondly, the fleece might be grown more uniformly fine over the body: and thirdly, almost all the South Down fleeces have a few grey or black hairs intermixed, which is a great defect where the goods made from it are intended to be stoved white. At present, the finest part of the South Down fleeces, called by the wool-stapler the prime, does not bear half the price of the prime Spanish, or R wool, from the best Merino flocks. In the South Down fleeces very rarely more than one-fourth part is of the best quality; but in the Merino breed full two-thirds of each fleece will be of one uniform quality, and that the prime or R wool. In the South Down fleeces, those parts from the buttocks and flanks will also be as coarse as the coarsest wool from heavy sheep. These defects in the South Down fleeces are common to almost all our native fine-woolled sheep, except the Ryeland; but we conceive they admit of a remedy without any injury to the form of the animal, or the weight of the fleece. If the opinion of an intelligent wool-stapler were first taken on the qualities of the different fleeces of those ewes from which it were proposed to raise a stock, and selecting for them some of the best formed rams bred from South Downs and Merinos, called Anglo-merinos; from this progeny the most perfect forms might be again chosen: and if these were still too strongly marked with the character of the Merino form, another cross with perfect South Down ewes would produce a progeny from which a race might be selected possessing whatever was desirable in the carcase, with a considerable amelioration of the fleece, both in the fineness of the wool and the regularity of the quality, over the greater part of the skin. The weight of the fleece would also be increased, for the wool is grown closer and thicker on the Merinos than on any of the English breeds; and this property continues in the crosses from that breed. The advantage of employing an intelligent wool-stapler to judge of the quality of the fleeces will be admitted, when we consider that a fibre of the finest wool is perhaps little more than the two-thousandth part of an inch in diameter; and that a variation from this, which is too small to be visible by the unpractised eye, may occasion a difference in price not less than 40 per cent. Indeed, it is truly astonishing that the eye can detect this microscopic difference unaided by instruments. Nothing but long and constant practice can secure the facility of determining the fineness of wool; and the most experienced dealer in English fine wool, were he to discontinue entirely the examination of wool for three months, would not be able, at first sight, to ascertain its quality and value to 15 or 20 per cent., supposing no change to have taken place in the markets. Can it then be supposed that a grazier, who has never acquired this fine sense of vision, and to whom wool is only an object of particular attention at one season of the year, we say, can it be possible for such a person to be an accurate judge of the quality of wool, and the comparative fineness of fibres ranging between the fifteen-hundredth and

## SHEEP.

the two-thousandth part of an inch? Yet many of our English wool-growers will decide, with the utmost confidence, whether their wool be finer or coarser than it was in the former year; or rather, they will decide that their wool is always growing finer. To this great confidence of the wool-growers, and to their real ignorance on this subject, more than to any other cause, may be ascribed the little improvement in the culture of English fine wools prior to the introduction of the Merino breed into Britain.

The South Down breed, in its improved state, is likely to supplant most of the English fine-woolled breeds, except perhaps the Cheviots in Northumberland, which are become habituated to the severity of the climate, on the elevated hills in the northern parts of that county bordering on Scotland. This race we think much better suited to supplant the coarse-woolled sheep in the Highlands of Scotland, than another of our English breeds. The Cheviot sheep are described by Mr. Culley, an intelligent farmer in Northumberland, as hornless; the faces and legs are, in general, white: the *best kinds* have a fine open countenance, with lively prominent eyes; the body long, fore-quarter wanting depth in the breast, and breadth both there and on the chine; fine, clean, small-boned legs; thin pelts; weight of carcase, when fat, from 12lbs. to 18lbs. *per* quarter; fleeces from 2lbs. to 3lbs. The qualities of the Cheviot fleeces are various; some of them contain a small portion of fine wool, which, as we have before remarked, is more soft than any of our native English wools. The price at Lord Somerville's annual show in 1813, for the best cloth from English wool, was given to Mr. J. F. Smith, for a piece of cloth manufactured from the prime part of the Cheviot fleeces.

In general, the quality of these fleeces might be much improved by a judicious selection. The great defect is, that in the finest fleeces only, a small part is of the best quality. Some of the Cheviot sheep are speckled on the face and legs; but these are probably a mixed breed, from crossing at different times with Heath sheep, to whom they have long been neighbours; for leaving the heights of Annandale to the eastward, we insensibly lose the Heath sheep and mixed breeds; after which all the extensive fine green hills on the Scotch and English borders from the sides of the Cheviots to the barren heaths of Lammer-muir are covered with the Cheviot breed. The best *kind* of these sheep is certainly a valuable mountain-sheep, where the pasture is mostly green sward, or contains a large portion of that kind of herbage, which is the case with all the hills around the Cheviots, where these sheep are bred; and the fine herbage which the border hills every where produce, supports them so well in summer, as to enable them to stand the severities of the winter.

The shape of this breed of sheep has been greatly improved of late years, but will still admit of much improvement. "We cannot (says Mr. Culley) expect the perfection of this breed of sheep can be obtained at once, it must proceed by slow gradation, as every other improvement hath done.

"That breed of sheep which brings the most profit to the farmer will always be preferred, but this object is not to be obtained in this district by fine wool alone. Perfect mountain sheep should be hardy, well-formed, and quick feeders. These qualities will always recommend them to the grazier; but if to these qualities, so essential to the sale of a mountain farmer's flock, can be added a fleece of fine wool, a breed of sheep might then be obtained, the properest for a hilly district of any we have yet seen. There is little doubt but this may be accomplished by proper selection, and probably

the best kind of Cheviot sheep, from their hardiness, and producing a portion of fine wool, are the properest flock for laying the foundation of so desirable a change." With these sentiments of Mr. Culley we entirely agree, and particularly in the propriety of selecting from the best Cheviots to lay the foundation of a valuable stock of mountain sheep, which might supplant the coarse-woolled Heath sheep in North Britain. Every situation may be said to have its peculiar advantages for particular breeds of sheep; and the rage for improvement, and desire of change, have in some instances been carried too far. There can be no doubt, that the rich pastures on the eastern side of England are better suited for heavy long-woolled sheep than for South Downs or Merinos, whilst it would be folly to attempt to stock the mountainous parts of Britain with the Dishley or Lincolnshire breeds. But many of the flocks in the uplands are susceptible of much improvement by selection, without any admixture, and in very exposed situations it might not be desirable to attempt improvement by introducing a less hardy race. In dry and moderately elevated situations there are none of the finest-woolled native or Anglo-merino breeds, that might not be cultivated with advantage; but we are well persuaded, that with the present demand for, and price of animal food, the breed which will send into the market the largest quantity of good meat in the shortest time, will have the preference over any superior quality of the wool alone. On which account the improvement of the South Down breed, which combines both advantages, is perhaps an object the best deserving attention, in all situations suited for fine-woolled sheep, that are not too much exposed to the inclemency of the climate.

A particular race of sheep exist in the Shetland islands, which produce a fleece more like that from the sheep on the mountains of Thibet, than any of the European sheep with which we are acquainted. From the report of Mr. Thomas Johnson, addressed to the British Wool Society, it appears that there are two varieties of Shetland sheep.

One of these varieties carry coarse wool above and soft fine below, and have three different successions of wool yearly, two of which resemble long hairs more than wool, and are termed by the common people *fors* and *scudda*. When the wool begins to loosen at the roots, which generally happens about the month of February, the hairs or *scudda* spring up; and when the wool is carefully pulled off, the tough hairs continue fast until the new wool grows up about a quarter of an inch in length, then they gradually wear off; and when the new fleece has acquired about two months' growth, the rough hairs termed *fors* spring up, and keep root until the proper season for pulling it arrives, when it is plucked off along with the wool, and is separated from it at dressing the fleece, by an operation called *forfing*. The *scudda* remains upon the skin of the animal, as if it were a thick coat or fence against the inclemency of the seasons, which provident nature has furnished for supplying the want of the fleece. See the preceding article SHEEP.

The native or kindly breed, which bear the soft cottony fleeces (as they are called), are rather of a delicate nature; their wool is short and open, and destitute of a covering of long hairs. These soft-woolled fleeces are very often lost or rubbed off, during the winter or early in the spring, which it is supposed might be prevented by clipping or shearing the sheep, in place of pulling off the wool, a barbarous practice, tending to weaken the sheep and hurt the length of the staple.

The Shetland sheep are of various colours; the silver-grey wool is thought to be the finest and softest, but the black, the white, the mourat, or brown, is very little inferior; it

## SHEEP.

is all of the softest texture, fit for the finest manufactory, and in some instances has been found to rival Spanish wool itself: but the pure white is generally the most valuable for all the finer purposes for which combing wool can be used. For softness and for lustre, no wool equals it; and the skin, with the fleece on, can be converted into a fur of very great value, some specimens of which have already been sent to the China market.

They are in general very hardy. In the winter season, when the ground is covered with snow, they eat the seaweed very greedily, and often during long and severe snows they have little else to live upon. Nature seems to have imparted to them a perfect knowledge of the time at which this food may be procured; for immediately upon the tide beginning to fall, the sheep in one body run directly down to the sea-shores, although feeding on the hills several miles distant from the sea, where they remain until the tide returns and obliges them to seek their usual haunts.

It is to be regretted, that we know so little of this peculiar race of sheep, or of the time when they were introduced, and the country from whence they came. The wool, though intermixed with coarse hairs, possesses a most extraordinary degree of softness, approaching, if not equaling, that from the sheep of Thibet, and might, if proper attention were paid to it, be applied with advantage to the manufacture of shawls and other articles now imported from the East. None of the European wools which we have seen, possess this quality in any degree to be compared with that from the Shetland sheep. The circumstance of the fine wool growing as down under a pile of coarse wool or hair, is not peculiar to these sheep. We believe that unmixed fine wool is rather a product of cultivation than natural to the animal in a wild state. In the argali, as well as in numerous animals, the inhabitants of cold countries, the skin is covered with a short fine down, and this is protected by a covering of longer coarse hair growing through the former. By regular keeping and warmth, the coarse hairs fall off in many animals, and this has probably been the case originally with all our fine-woolled sheep, many of which, if neglected, shew indications of their original condition, growing coarse hair intermixed with the finer parts of the fleece. Even in the coarsest woolled sheep of cold countries, such as the Heath sheep in the Highlands of Scotland, we have often seen a small portion of fine wool growing under the coarse fleeces with which these animals are covered. It appears to be a beneficent provision of the Author of nature, to accommodate animals to different climates. European sheep removed between the tropics, languish and become sickly from excessive heat, and lose their fleeces in the course of the ensuing year. They are afterwards covered with a thin crop of coarse short hair. We have seen a finely-shaped ram, of the European breed, brought from Louisiana, which was entirely covered with white hair, as coarse and short as that on a dog. We have no doubt, however, that in hot climates, where sheep have the advantage of a mountain pasture, that with care and proper shelter these fleeces might be preserved, but they would certainly be a useless incumbrance. Fine fleeces seem to be more peculiarly the produce of cool or temperate climates; for it is observed, in most of our English sheep, that the part of the wool or staple which is grown during winter, is finer than that part which is grown in summer. Extreme heat and cold appear to have both an effect upon the skins of sheep, to cover them with coarse hair; but in cold climates there is also a tendency in the animal to produce a fine down underneath. It is not improbable that the Shetland sheep may have been originally descended from the Tarentine breed, the "molles oves," which

the Romans had introduced into Britain; their insular situation protecting them, in a considerable degree, from intermixture. For, according to Dr. Anderton, though the coarse-woolled Heath sheep are introduced into these isles, the native active sheep frequenting the more desolate wilds at the greatest distance from man, withdraw themselves from the others, and thus the breed is only partially debased by accidental stragglers. The whole system of management, respecting these sheep, is directly the reverse of what it should be, and it is truly astonishing that they have preserved so long the peculiar softness of the wool. Could these sheep be introduced into more favourable situations, and proper attention paid to them, we have no doubt that their wool might be grown free from the coarse hairs with which it is at present intermixed; it would then be of far greater value than the finest Merino fleeces, as it might be applied to the fabrication of shawls, approaching in softness to those of Cashmere.

We have now to describe the long-woolled breed of sheep, which may be considered as almost peculiar to Great Britain and Ireland; for though sheep of this breed are found in Flanders, and some other parts of Europe, their number is inconsiderable; and they no where exist with the same perfection of form, and producing the same quantity or quality of wool as in the united kingdoms. Their fleece is the envy of the other manufacturing countries of Europe, and can only be grown upon rich pastures. Long combing wool, and the varieties, will be described under the article WOOL; but it may be necessary here to state that the longer kind varies from six to about nine or more inches in the length of the staple, or filaments. In the manufacture of this wool by the comb, the fibres are laid parallel; whereas in short-clothing wool, they are broken in all directions by the cards.

Long wool is manufactured into shalloons, camblets, moreens, bombazeens, and various other articles; and a large quantity is also manufactured into what is called horse-millinery, consisting of girths, fringes, and other articles of use or ornament in equipages. The coarser kind makes the warps for carpets.

Short combing wool is manufactured into hosiery.

The Lincolnshire sheep may be considered as the original of our heavy sheep in England. These, with the new Leicester or Dishley breed, have nearly supplanted the other varieties of long-woolled sheep. The Lincolnshire breed has also been generally somewhat changed of late, by an intermixture with the Leicester breed. The original Lincolnshire sheep have no horns, and long carcasses; the ewes weighing from 14 lbs. to 20 lbs. per quarter; the three-year old wethers from 20 lbs. to 30 lbs. The average weight of the fleece is about  $9\frac{3}{4}$  lbs., or three fleeces to the tod of 28 lbs. Some of the heavier fleeces weigh 14 lbs. The richer parts of Lincolnshire will support five of these sheep on the acre; and when we take into account the price of the wool, which in 1814 was 2s. per pound, it will be seen that the sheep of this description are the most profitable for the lands to which they are suited. The improvement made in their form, by the mixture with the Leicester breed, reduced the weight of the fleece; but the extraordinary demand for heavy combing wool is inducing some of the farmers to return to their heavy breed. It is probable that this kind of wool will not soon fall under 1s. 6d. per pound; and the production of a fleece, which weighs 10 or 12 lbs., must be an object of attention to the grower, not less than that of the carcase. For though the wool from the Leicester breed is somewhat finer, the weight seldom exceeds 7 lbs., and the difference of price is not more than about 2s.

*per tod* of 28 lbs. The advantage of the latter breed consists in being made fit for the butcher in less time; in this it exceeds all the other breeds before known. At the time when Mr. Robert Bakewell of Dishley, in Leicestershire, directed his attention to the improvement of sheep, the price of long wool was less than *4d. per pound*: the fleece was hence of little value to the grower, and Mr. Bakewell was exclusively employed in improving the carcase of sheep, and all other domestic quadrupeds. Previously to about the middle of the last century, little attention was paid to the improvement of live-stock, except horses. Nothing could be more repugnant to common sense than the general practice of farmers: they selected for slaughter that part of their flock which was most disposed to fatten, as offering them an early profit; the remainder were left to breed from promiscuously. A considerable part of England was then uninclosed, and the flocks of different proprietors being unavoidably intermixed, prevented a due regard to the improvement of the breed. Mr. Bakewell commenced his improvements subsequent to the year 1760, and succeeded in exciting the attention of the public to the amelioration of live-stock, by shewing the most effectual method of accomplishing this important object. The principal object which Mr. Bakewell had in view, in his improvement of different animals, except horses, was to produce the greatest weight and value of flesh, with the smallest expence of food.

Availing himself of the observations which he had made on different animals, that certain peculiarities of form were always attended by a disposition to grow fat, and that animals inherit this disposition from their ancestors; and if they are kept free from intermixtures with other breeds, in the course of a few generations the peculiar properties will be perpetuated, and form a distinct race; the laws of animal life being in this respect regular and permanent. He, therefore, selected from his own flock, and from the flocks of others, those sheep to breed from, which possessed in the greatest degree that perfection of form he was desirous to attain and perpetuate. By judiciously crossing them, and selecting the most perfect of their progeny, he at length succeeded in forming the breed, which has been distinguished by the name of the new Leicester or Dishley breed; and having attained his object, he carefully guarded against any future intermixture with other breeds. This breed exceeds all others in its propensity to fatten; and by crossing with rams from this breed, a very considerable portion of the long-woolled sheep in England have been greatly improved in this respect.

The peculiar characters of these sheep have been well described by Mr. Cullley, an eminent grazier in Northumberland, who introduced the breed into that part of England. "The Dishley breed are particularly distinguished from other long-woolled breeds, by their fine lively eyes, clean heads, straight, broad, flat backs, round (barrel-like) bodies, very fine small bones, thin pelts, and inclination to fat at an early age. The last property is probably owing to the before-specified qualities, which, from observation and experience, there is reason to believe extends generally through every species of domestic quadrupeds. The Dishley breed is not only peculiar for its mutton being fat, but also for the fineness of the grain: the flavour is superior to the mutton of most other long-woolled breeds. The weight of the carcase may be stated in general: ewes, three or four years old, from 18 lbs. to 26 lbs. *per quarter*; wethers, two years old, from 20 lbs. to 30 lbs." The fleece is stated by Mr. Cullley at 8 lbs.; but in Leicestershire, we believe, the average weight is not more than 6 or 7 lbs., about four

and five to the tod. The wool is finer and shorter than the Lincolnshire, and a portion of it is better suited for the hosiery trade than for thin goods, such as shalloons, &c.; but considering the difference of weight, the fleece is not so profitable to the grower as that from the Lincolnshire sheep.

There are two reasons for killing the wethers of the Dishley breed at two years old: first, they leave the most profit; and, secondly, if kept longer, they grow too fat for genteel tables. It is very common for two-years old wethers to cut four inches thick of fat on the ribs, and from two to three inches all down the back. Even ewes of this kind, which have bred and suckled lambs till July, when killed about the Christmas following, will frequently measure four or five inches thick of fat on the sides, and two or three inches down the back, all the way from the head to the tail; and though sheep of this breed are not eminent for much tallow, yet ewes, under such circumstances, generally produce from 18 lbs. to 24 lbs. of tallow each. This mutton is not so inviting as the leaner kinds, but it finds a ready market among the manufacturing and laborious part of the community.

The graziers in different parts of England, who had been too negligent respecting the improvement of stock, no sooner became sensible of the possibility of forming a race of sheep, that would produce a large weight of meat in a much shorter time than before known, than they became desirous of introducing the breed; and the taste for growing fat meat became generally adopted, and in many instances without proper regard to other considerations. In some instances, fine-woolled flocks were crossed with this breed, and it was vainly expected that they should preserve the quality of the wool, and increase the carcase at the same time. In other instances, the Leicestershire breed were introduced on land only suited for a lighter race of sheep; and even where the pastures were suitable, the propensity to fat was encouraged, until it became a disease, and the animal was scarcely able to move under its own weight. Whatever the advocates of this breed may advance in its support, it cannot be contended that the mutton is equal in flavour to that of the smaller sheep.

The object of Mr. Bakewell was in these instances mistaken: it was not to produce meat for the tables of the rich, but to supply substantial nourishment for the working classes. We have heard him say, "a small quantity of this fat meat, cooked over a large dish of potatoes, is a good dinner for a poor man's family; and this is what I proposed in the selection of the breed."

The increased demand for animal food could not have been supplied had not some improvement taken place, and the working classes will ever prefer the fattest meat. In this respect they resemble the North American Indians and the back settler, who regard fat as the only nutritious part of meat, and accordingly Volney describes the lean by a name which signifies *meat bread*. The rage for excessively fat meat has in some degree subsided, and the new Leicesters are likely to be confined to those districts which are peculiarly suited for their growth, and the object of the grazier will be directed to producing a large quantity of meat for the consumption of the working classes. Instead of attempting to improve the fine-woolled breeds by crosses with a heavy race, it would be more judicious to pursue the same plan of improvement with those breeds which Mr. Bakewell attempted with such success in the heavy sheep.

The improvement of the carcase may, we are convinced, be effected without injuring the quality or diminishing the quantity of the wool. Of this Mr. Bakewell was well aware,

## SHEEP.

aware, but the price of wool in England at the time of the American war (the period of his celebrity) was so low, that he used to say, it would be desirable to grow sheep without wool, and confine the attention to the carcase exclusively.

In selecting the most profitable breed of sheep for a farm, it can never answer to stock hilly districts with a heavy race of sheep, and in such districts the improvement of the wool is an object more particularly deserving attention, because we believe it would be possible to grow an equal weight of wool of a much finer quality than what is produced by many of our coarse-woolled breeds of sheep, and particularly by the Heath sheep, which pasture the mountainous parts of North Britain.

In rich pastures, weight of carcase must in a considerable degree supersede the improvement of the wool, at least so far as relates to its fineness; for the real interest of the grower of long wool is to produce a heavier fleece. At the present price of wool, a Lincolnshire fleece of twelve pounds being more valuable than any other native English fleeces. To combine, therefore, the perfection of form in the Dishley breed with the heavy fleece of Lincoln, is what will best reward the owners of long-woolled flocks.

There are, besides long and short-woolled sheep, numerous flocks which produce wool suited for the comb, but of a finer and shorter kind than the heavy combing wool. The worsted yarn made from this wool is spun soft, and manufactured into hosiery. A very considerable quantity of wool, suited for hosiery, is grown in the county of Kent; but the breed of sheep which produce it, has not any distinct name, and appears to have originated from an intermixture of the short-woolled sheep of the southern counties with heavy long-woolled sheep. We believe there is no country in Europe, which at present produces combing wool of this kind equal in quality to that grown in England. See WOOL and WORSTED.

SHEEP, *Stealing of*, is now made felony without benefit of clergy. See CATTLE.

By an ancient statute, no person shall keep, at one time, above two thousand sheep; but lambs are not to be accounted sheep till they are a year old. (25 Hen. VIII. c. 13.) Persons exporting sheep shall forfeit them, and 20s. for every sheep, &c. (12 Car. II. c. 32.) And persons in the counties of Kent and Sussex, within ten miles of the sea, are to give an account, in writing, after sheep-shearing, of the number of fleeces, to the next officer of the customs, &c. (9 & 10 W. III. c. 40.) See WOOL.

SHEEP, *Clatting of*, in *Agriculture*, a term given to the business of preparing the ewes of them for lambing in some places, which commonly takes place about a week before the lambing season commences. In such cases the ewes are usually driven into a pound, when the clatter, looker, or shepherd, draws them out singly and separately, turning them upon their backs, and removes with the shears the locks of wool from the undersides of their tails, from about their udders, and from the insides of their thighs. This becomes necessary, in consequence of the dirt and filth which often adhere to the wool about these parts, especially in moist growing spring seasons, when the ewes are affected with much purging. The wool being removed in this manner, not only renders the parts more neat, but enables the lamber, or person who has the care and direction of the business of lambing, to distinguish when the ewes have lambed, by the mark or stain which is generally left on the back parts of the udders; as, if such marks were not to occur, he would sometimes be at a loss, as the

young ewes not unfrequently desert their lambs, and endeavour to escape along with the other ewes, pasturing as unconcernedly as if nothing had happened to them.

Some think, that it would also be a good method at this time to have the different ewes marked in a different way about the face, in the order of their lambing, and to have those of different forwardness put together into separate suitable pastures, to be taken care of in the most proper ways.

The barren ewes, or those not with lamb, are likewise now distinguished by the clatter, looker, &c. by their not having any enlargement of their udders or their bellies, as well as by their jumping and skipping about in a nimble manner; such being usually turned off directly upon the fattening grounds.

SHEEP, *Lambing of*, the business of managing the lambing of the ewe flocks, which is very essential and important, though but little known or attended to in many places, even where sheep are almost the whole stock of the farmer. However, in consequence of this, and the employing of unskilled persons, much loss is not unfrequently sustained, to the great injury and inconvenience of the sheep-grazing farmer. In some situations, as those of the inclosed, dry, and warm kind, and the more poor mountainous ones, as well as the upland pastures and downs, such a very minute attention to this business need not, perhaps, be bestowed, as accidents less frequently occur, than on rich pastures or marshes, where the lambs are much exposed to danger and destruction from many causes, unless very carefully attended to at this time. The nature of the principles and practices which are necessary in the business of lambing, are, in short, yet much too confined and too little known to sheep-farmers in general to be of any great advantage. The first thing which is requisite in preparing for this business, is the making choice of proper dry warm fields and pastures for the purpose, and having them made as safe and secure as possible from the danger of all sorts of accidents and inconveniences to the lambs. Where they have large wet open exposed ditches, or any other sort of inconvenient fences on their sides or other parts, they should be well guarded and secured by means of suitable low dead or other hedges being raised on the sides of them, by the use of small light hurdles, about two feet in height, with two racks, fixed down around them or in the most dangerous parts; by placing brush-faggots of a proper size round the sides of their banks, and staking them well down to prevent their being disturbed by the winds and storms: by hanging old sea-nets along their banks or borders; or by some other kind of cheap low defence, which the local nature of the situation may suggest. The nature of the pastures for this use should constantly be such as are fine and short in their grass, and neither of too poor nor too rich a quality, as inconveniences are liable to take place from each of these states.

It was formerly the practice to have the lambing of the ewe flocks performed on a great breadth of pasture-land, as two or three to the acre, or in a very thin manner, which was extremely troublesome; but it is now found that much benefit attends its being done in a clover or thicker way, as ten or twelve more to the acre, in some cases; as it is not only more convenient and successful, but far more profitable. By thus doing it in a narrow compass, according to the state of the grass, the work is more safely gone on with, is more under the direction of the manager, and more convenient in case of difficulties arising in it, while there is much less danger of loss among the ewes in consequence of the nature of the keep, which is very material, as it is often

often by no means inconsiderable, especially in certain circumstances and situations towards the close of the lambing season.

In some places it is not unusual, before the lambing takes place, to provide a better sort of pasture-field for the reception of such ewes as may chance to have twin-lambs, as more food is required for them. This is best when in or near the middle part of the lambing pastures, as the ewes and lambs, in that case, can be the most readily and conveniently removed, whereas in other circumstances there is often much trouble and difficulty caused with the young lambs, which should always be marked and removed as soon as they are enabled to walk.

The next preparatory business, in some situations, is that of clatting the ewes, which commonly takes place a little time before the lambing begins; but in many places this is wholly neglected and thought quite useless. See SHEEP, *Clatting of*.

The lambing time takes place at different periods in different places, according to the nature of the situation and other circumstances, and often a week or ten days sooner or later in the same situation, as the season may be more or less severe, and the stocking of the land has been more light or more hard. But about the beginning of April is probably the best and most general time. Early lambing is mostly advantageous, where the circumstances of the land will admit of it. The season of lambing mostly continues about a month, and in some places, where lambers are employed without any lookers, two guineas and the lamb skins are paid for that time.

In the actual business of lambing, much care and attention are necessary in the person who has the direction and management of it. In all natural cases of this sort the less that is done, perhaps, in general, the better, as nature will for the most part effect the business in the safest and most proper manner. The chief difficulty, it has been said, consists in knowing when ewes should be assisted, as young persons employed in this management are much too apt to interfere, from which much mischief and loss not unfrequently proceed. The nature of the particular case, and the workings of the ewes, should constantly be the principal directors in this matter. Some conceive, that when ewes have been at work some length of time, they should be assisted; others, that when the lambs' tongues are protruded from the mouths, they should have assistance; but neither of these rules is always to be depended upon. There are still others who think, that when the ewes rise and walk off on being approached without any thing being the matter, they require no interference; but that when they will not rise, but appear a good deal spent, they should have immediate assistance. Some also suppose, that considerable force may be exerted in such cases without danger. But though there may be some truth in the remark, it is always necessary that much caution should be taken where force is employed on these occasions. Besides these, something may probably depend upon the state of the seasons in this business, as assistance will be less necessary in such as are cold, than when they are warm. The ewes should, in fact, never be meddled with in their lambing, in these cases, until there is an absolute necessity.

In all unnatural cases of this kind, which vary very much in different instances, according to the nature of the unusual part of the lamb which may present itself, and which require the assistance of proper person; those who have had the fullest experience, and are the most cool and cautious, will be the most proper for performing the business, as where this is not the case, there will often be

great loss of lambs, as well as of ewes. In every case of this nature, where much force, or any other means are necessary to be employed, very great care and circumspection should constantly be used to have it exerted and done in the most gentle, deliberate, and safe manner possible, as otherwise much danger and inconvenience may arise, that might have been avoided.

In some instances, where the lambs are apparently dead when they are lambed, they may be recovered and restored by forcing air into their lungs in an easy manner. This should however always be done almost instantly afterwards, otherwise it seldom succeeds.

As soon as the lambs are brought forth, they have commonly some milk from their mothers given them, or are allowed to suck them for some little time, which are supposed to increase the affection of the ewes for them; the lambs being at last left as close by the noses of the ewes as possible, which should be done quickly, that they may not go away without noticing them. The lambs are always greatly strengthened and improved by the ewes licking them, which they constantly do, where they have a proper affection for them. When lambs droop and hang their heads immediately after they are lambed, they are bad and unfavourable signs, as shewing them to be in a weak and dangerous state. The practice often made use of in some places, of putting the tail of the lamb, which is just lambed, into the ewe's mouth, in order to promote her affection for it, is very silly, and of no avail.

In the catching of all ewes in the lambing state, every sort of exertion, trouble, and fatigue, so as to injure them, should be avoided as much as possible, in order that they may lamb, or be assisted to lamb, in a cool suitable state.

During the time of lambing, the looker, or other person who has the management, should be very careful and attentive early in the morning, and at other times, in looking over the ewes and lambs, to see that they are not injured or lost by neglect in any way.

In cases where this business is carried on upon a large scale, when every thing has been properly prepared and got in readiness, the labour, or other person employed in the management, begins his laborious and difficult undertaking, by entering and going over the lambing pasture at the time of day-break, with his lamb-hook in his hand, that he may notice and examine the ewes, raise up such as have lain down, and determine whether such lambs as are dropped be capable of suckling, which is commonly readily decided by the distension of the belly. In cases where this last is not able to be done, the ewe is either caught, and the lambs suckled, or the lamber is provided with some ewe's milk in a bottle for the purpose; a precaution which is usually proper on many occasions, as when the weather is severe, wet, and stormy, in which circumstances the lambs quickly perish, if not supplied with such food. This attention often strengthens the lambs in a wonderful manner, and prevents much trouble in removing them and the ewe to the pounds. The continuance of the affection of the ewes is proved by the calling and noise they make. The twin lambs are now usually marked, to prevent confusion, as the ewes frequently leave one of them, after which they are not meddled or interfered with for some little time, as a few hours, or a day, after which they may be; but as soon as they can walk, they are mostly removed with the mothers into better keep. The ewes which have single lambs commonly remain in the pasture-field where they have lambed, unless the number be great, in which case, the lambs with the ewes are occasionally removed into the pasture-fields, where they are intended to be kept during

## SHEEP.

the summer. It is supposed, that by the above practice the lambing pastures are sometimes less discommoded, than is the case where too great a number of ewes and lambs are crowded together. Sometimes, when an ewe has lost her lamb by any accident, and yet is deemed capable of bringing one up, a twin lamb is given her. When a weakly lamb, however, is put to an old ewe, the milk is often too strong for it, and will speedily cause its destruction, by scouring or in other ways; such lambs are likewise incapable of keeping the udders of the ewes properly drawn, by which means much injury is frequently done to them. These ewes are therefore often better turned off for fattening, than being employed in this way. Various methods are practised with the ewes which have dead lambs, by using such lambs so as that their affections may be increased, and the ewes be drawn into the pounds, and have other lambs put to them. All such measures, however, often fail. The custom of running the ewes down to get them into the pounds is always very bad, as frequently causing their destruction. The ears of ewes being flapped down, and the ewes not looking back, are in every case bad signs of affection, but the contrary good ones. Lambing pounds are mostly supplied with suitable pens or coops for the convenience of suckling the strange lambs in. And the coats of the natural lambs are sometimes employed on the others. Whatever is done in this way, must, however, be done by deception, and not force, as the ewes are very refractory. Many other modes are had recourse to in different cases for taming the refractory ewes, and causing them to suckle the lambs in a proper manner.

It will now be necessary for the lamher to be particu-

larly careful of the twin and other lambs, to see that they are regularly kept, and properly suckled in all cases, especially those which are in a weakly state. For this purpose some milk of the cow or other kinds is often carried and made use of by him, which prevents trouble afterwards. In these intentions, it is proper to go over the fields twice or oftener during the day; and to be particularly attentive in cold stormy weather. All sorts of accidents and dangers are at these times to be looked to, and guarded against in the most cautious manner.

About the end of the first week of the lambing season, one-half of the ewes will mostly have lambed, and more than two-thirds of them probably at the termination of the second, when the ewes may be brought into a less compass, and the lambing-field or pasture be cleared of all the twins and most of the single lambs, and they which are necessary may be had ready to cut, which in suitable circumstances is often done at this early period, by which the manager will be freed from much of his future labour and trouble.

By this sort of cautious attention and management in the lambing of the ewe flocks, and the use of proper sorts of shelter, a vast saving of lambs and ewes may in all cases be made, and the interests and profits of the sheep-breeding farmer be very greatly aided and promoted. See SHEEP.

SHEEP, *Names of*, the several names which are given, applied, or appropriated to them, at different ages, in different parts and places where they are much kept. These are very numerous, and of a very local nature; but the following are the greatest part of them.

Times.	Males.			Different Sexes.		Females.		
	Borders of Scotland.	Lincoln.	Dorset.	Norfolk and Suff. &c.	Borders.	Lincoln.	Dorset.	
From that of being lambed until that of weaning - - -	Lambs.	Lambs.	Purs.	Lambs.	Lambs.	Lambs.	Chilvers.	
From that of weaning until that of the first clip - - -	Hogs.	Hogs.	Gridlings.	{ Hogs and } { Hoggits. }	Hogs.	Thraves.	Thraves.	
From that of the first to that of the second clip - - -	Dinmonts.	Heeders.		Shearlings.	Gimmers.	{ Gimmers } { and } { Sheeders. }		
From that of the second until that of the third clip - - -	Young } Wedders. }			Two-shear.	Counters.			
From that of the third clip forward - - - - -	Old wedders.			Three-shear.	Fronters.			
From that of the fourth clip ever afterwards - - - - -	Full-grown } sheep. }				Ewes.			
Such ewes as are broken mouthed and refuse are denominated -	Crones in Norfolk and Suffolk.			Drapes and } Drape ewes } in Lincolnshire and some other counties.				
Such ewes as are neither with lamb nor give milk, are said to be	Eild, or Yield in Scotland.							

These arbitrary names, which are given to sheep at different periods of their existence, in different parts of the country, serve to guide the breeding and grazing sheep-farmers of such places in their management with these animals.

SHEEP, *Smearing of*, the practice of salving or laying them over with some sort of substance of the unctuous kind, for the purpose of improving the wool, and preserving the animals from disease. It is only had recourse to in some districts, and those mostly in the northern parts of the kingdom. See SALVING of Sheep.

Raw unboiled tar, not mixed with butter, is sometimes

very dangerous and hurtful to sheep, especially rams, when laid on in large, or even moderate quantities. There are, indeed, some sorts of tar which are very acrid, and blister sheep, causing the wool to fall off, and the death of the animals. When it is thin, and appears black on stirring, with an offensive smell, and caustic acrid taste, it should never be used for sheep, especially without boiling, to destroy such properties. The persons engaged in the work of smearing often find proofs of the danger of this sort of tar, in the burning effects which it has on their fingers. Good smearing tar, it is said, on being stirred, has a thick, brown, ropy

## SHEEP.

ropy appearance, and a more pleasant smell, with a less acid taste than the other kind. Tar should probably always be well mixed with butter in performing this sort of work.

**SHEEP, Teeth of,** the parts of the mouth of these animals by which their ages are often, in some measure, ascertained. When full-mouthed, they have usually eight teeth of the incisor kind in the lower jaw. They throw up two such each year until this takes place, by which means their sucking teeth are displaced or lost. See *AGE of Sheep*, and *TEETH*.

**SHEEP-Shearing,** in *Rural Economy*, the business of clipping or cutting off the coats or fleeces of sheep, by means of shears constructed for the purpose, which are termed *wool-shears*. It also sometimes signifies the season in which this sort of work is usually performed, which was formerly, and is even in some cases at present, a sort of festival. The operation is performed in different ways by different persons, but the best mode is that of the circular, or round the sheep, instead of the longitudinal, which is at present most in use. It is usually performed about June or July, according to situation and season, but should not be done either too early or too long protracted, as injury and inconvenience may attend either extreme. A good clipper is capable of clipping from seven to fourteen or fifteen, and up to twenty or twenty-five in the day; and more are frequently done by very expert persons. Great care should be taken not to cut or prick the animals; but where this accident happens in the northern parts of the kingdom, they touch the part with a little tar, or sheep-salve; and in Sweden it is often done with train-oil and resin melted together. And in addition to what has been already observed on this subject, it may be stated, that much improvement has taken place in this art, especially in the more southern districts of the kingdom, in making use of the mode of clipping round the sheep, which has gradually extended itself from the northern districts of the island; by which less wool is lost by being left upon the sheep, and the business performed in a more expeditious, neat, and convenient manner. It was much the practice formerly to clip lengthways of the sheep, and in some cases in many different directions, according to the convenience of the person who executed the work, by which means it was often ill done. And in Ireland it has been stated, that they clip in short strokes, catching a bit of wool first in one place and then in another; and that if they are not looked narrowly after, they will leave many parts, such as the heads, tails, and insides of the thighs, untouched.

We have, in speaking of sheep, noticed the most proper periods of performing this very important operation; and the following remarks, by Mr. Price, an excellent sheep-farmer in the county of Kent, with the comments of Mr. Culley, as stated in the *Annals of Agriculture*, will shew the proper mode of managing the sheep in the time of shearing, as well as the manner of executing the business with these sheep-masters. It is stated by the former, that the sheep-shearing in Romney-Marsh commences about Midsummer, and finishes about the middle of July. Those who shear first, think they escape the effects of the fly, and those that shear late, apprehend they gain half a pound weight in every fleece, by the increased perspiration of the sheep. In early shearing the wool has not the condition which it afterwards acquires, but the hot weather occasions a good deal of trouble in detecting the fly. In order to begin, a large pen is filled with sheep ready for the coming of the shearers, in number from four to twelve, in proportion to the extent of the flock. The time employed is from two to four days. The sheep are let into a small pen, thirty or forty at a time, and when taken out to be sheared, all except three, more are

put in, because one or two only left would be apt to jump out. A boy keeps the gate, and the account of the number sheared, with small leaden tellers. These shearers by profession differ much as to quantity and method of performance; never begin early, but are satisfied with eight or ten hours shearing: a good shearer will shear ten an hour, a bad one seven. Their emulation tends only to dispatch and profit, not excellence of performance, and the sheep are too often pulled about in a rude and barbarous manner, and even wounded by the shears with cuts of the length of three or four inches, and the wool left unevenly shorn: tar, or some ointment, is then applied carelessly by the boy, in order to keep off the flies. The master's office is usually to give the pitch-mark, and when one field is finished, the sheep are returned, and others are in readiness to take their place.

The common mode of *catching* the sheep is by the hinder leg, drawing the animal backward to the adjacent shearing-place, the hand holding the leg to be kept low; when at the place it is turned on its back. Or they are moved bodily, or one hand placed on the neck, and another behind, and in that manner walked along; the first, or common mode, he thinks the most safe. The parts of sheep fed on rich pastures, and fleshy, if handled hard, and bruised, are liable to fatal mortifications; an accident which often happens, on which account the pens upon some lands are obliged to be lined with woollens, or many would die from bruises. The price of shearing is 18*d.* or 2*s.* a score, with a dinner, and 2*s.* 6*d.* or 1*d.* a sheep without victuals, but with drink. They vary much in different places. A good winder will wind 400 fleeces a day, at the same price *per* hundred as the shearer has *per* score. The method of shearing—the left side of the sheep to the shearer's left leg, his left foot at the root of the sheep's tail, and his left knee at the sheep's left shoulder. The process commences with the shears at the crown of the sheep's head, with a straight cut along to the loins, returning to the shoulder, and making a circular shear round the off-side to the middle of the belly; the off hinder leg next: then, the left hand holding the tail, a circular shear of the rump to the near *back* of the sheep's hind leg; the two fore-feet are next taken in the left hand, the sheep raised, and the shears set in at the breast, when the remaining part of the belly is sheared round to the near side; lastly, the operator kneeling down on his right knee, and the sheep's neck being laid over his left thigh, he shears along the remaining side.

However, on these statements Mr. Culley has made the following practical comments; namely, that Mr. Price's observation is just, with regard to the benefit arising to wool from being late clipped, and that it is consonant with the opinion of the Lincolnshire graziers and breeders, who have paid more attention to the subject, and understand it better than any other of the profession in this island: but very great attention is required from the shepherd to keep the sheep, under the circumstances of late clipping, free from the fly and maggots, also from the danger of being *beaten* by small flies, which fasten on those parts where the points of the shears have made the smallest scratch. But that, in regard to shearing seven or ten sheep in an hour, nothing can be more absurd and improper than such attempts, since it is impossible for the best shearer to clip the lowest number within the time, and perform it well, as it ought to be done. Forty years ago, the same absurd practice prevailed in Durham, and particular men would clip sixty or seventy of that large breed in a day; but the consequence of such improvident haste was, that besides imperfect shearing, large pieces of skin were cut, particularly from the bellies of the sheep,

## SHEEP.

which, being constantly pestered and tortured in those parts by the flies throughout the summer, suffered much injury in their health and condition, some of them never recovering. Several sheep have died immediately after shearing, owing, perhaps, to having their legs tied, which, with hurrying and tossing them about, brought on a colic or cramp, putting a period to their existence in a moment. At that time, in a flock of two hundred sheep, we seldom escaped without the loss of one or two in a season; since, in the clipping of three thousand and upwards annually, we have not lost one these seven years. But, says he, instead of *tying* their legs, and *trying* who could clip the *most per hour, or day*, we have wisely begun to *try* who could clip the *best*, and from that change of system, instead of clipping fifty sheep *per day*, we think it a fair day's work to clip twenty-five upon an average. Where sheep are clipped by the great, and the men paid for number done, thirty or upwards may be sheared in the day; but our's are done by the day, without hurry, and scarcely wounding a sheep in the day. Each shearer makes his peculiar mark on the sheep, red or blue, that bad shearing may be detected; an useful stimulus to exertion. And he thinks that the sheep may be caught by the hinder leg, above the hough, but *not by any means* drawn backwards; on the contrary, as soon as the catcher has caught the sheep by the hough, he should draw it backwards, until he can, with his left hand, reach the throat, then, with the right hand behind its tail, he conveys it along with ease and safety. He thus continues: thirty years ago, it was the general practice in this county (Northumberland), and some old-fashioned bigotted people adhere to it still, to shear the sheep thus; the clipper first opened the belly, and then, after tying all the four legs, fat down upon a sack filled with straw, the sheep lying between his legs; when, in the most awkward manner, he slashed and tore the fleece off, beginning at the neck, and going down the left side first, finishing at the right. Instead of clipping around the sheep, as at present, they then clipped them mostly lengthways. The present method is to begin at the back part of the head, in order to give room for the shears to make their way down the right side of the neck, to the open of the breast. The man then sits down upon his right knee, laying the head of the sheep over his left knee bent, and beginning at the breast, clips the under side of the throat upwards to the left cheek; then takes off the back of the neck, and all the way down below the left shoulder. He then changes to the contrary side, and makes his way down to the open of the right flank. This done, he returns to the breast, and takes off the belly, after which it matters not which side he clips, because being able to clip with either hand, he meets his shear-points exactly at the middle of the back, all the way, until he arrive at the thighs or legs. He then places the sheep on its left side, and putting his right foot over the neck, and the other forward to the undermost hind leg, clears the right side; then turning the sheep over, finishes the whole.

Our price for clipping used to be one shilling *per dozen*, and a gill of ale about ten o'clock, and another at four in the afternoon. He supposes a man will have one shilling and sixpence *per dozen* now; but *we* clip all with our own men, mostly the shepherds, many of whom now do it most admirably; and we have in general prevailed upon them to clip with either hand; which is not only the easiest for the clipper, but enables him to do his work in the neatest and most complete manner.

These remarks deserve the regard of the sheep-farmers in other districts, as well as the following hint by Mr. Price. It is, says he, astonishing to see a good shearer handle a

sheep; he studies its ease, and the sheep seems delighted in its situation. This should always be the case with these animals, which are often much injured by coarse management, and the most sober steady men be constantly employed.

The fat sheep should always be shorn earlier than those which are lean. In the South Down sheep district, a good sheep-shearer is said to be able to shear fifty sheep daily, for which he has 2s. 6.; or 1s. the score, and board. Great care should at all times be taken not to injure the sheep in shearing, as the least cut is sometimes dangerous, though at others not. In cases of cuts, wax ointment or well boiled tar must be used, and the sheep have an open airy pasture.

The very same method is taken in shearing the lambs as in that of the old sheep, which, in many districts, takes place nearly at the same time, or about the latter end of June and the beginning of the following month; some shearing them immediately on their being weaned, but others some little time before, for the sake of allowing the old ewes to become fat. See *SHERLING of Lambs*.

The writer of the "General Treatise on Cattle," states, that the royal flocks of fine-woolled sheep in Spain are sheared in the beginning of May. There are shearing-houses, each of which will contain twenty thousand sheep, and cost in building above five thousand pounds sterling. To shear a flock of sixteen thousand sheep requires one hundred and twenty-five men, a man shearing twelve ewes, or eight rams, in a day. The sheep are sweated previously to being sheared, in a long, narrow, low gut, called the sweating place, where they remain a night, crowded as close together as the shepherd can keep them. The shorn sheep are permitted to go to pasture if the weather be fine, returning home in the evening, to pass the night within shelter of the walls, or in the house, if cold or cloudy; by which means they are brought by degrees to endure the open air.

And it is a point of great consequence in this business to have a person well conversant with the winding of the wool, in order that it may be well performed, and look in a proper manner to the buyer. In some places the wool is laid in a heap on being wound, and conveyed in the evening of the same day to the wool-lotts, or other depositaries. Some store their wool constantly in upper chambers, as the moisture which is produced by it on ground floors, when it is continued there for any length of time, is supposed to be very injurious to it. See *WOOL*.

*SHEEP-Fold*, in *Agriculture*, a space of arable or other land hurdled in for the purpose of being manured, or a sort of yard or other contrivance for the purpose of confining and keeping sheep in during the nights or in bad weather, in order to afford them protection and shelter. They are sometimes fixed, being constructed of any convenient sort of light materials, so as to inclose a space in proportion to the number of sheep in the form of a kind of yard or fold, which is kept constantly well littered with some sort of dry substance, such as stubble, refuse straw, dry sand, &c. during the time the sheep are folded and foddered in them, in order that as much manure may be raised as possible. In some cases also, for the more perfect protection of the sheep, they have sheds all round them, under which the sheep may lie without injury from rain, snow, or any sort of moisture. These are usually termed *standing folds*, and are either formed about the home-stalls, or in some dry, rather elevated situations, on the farms, having the bottoms well laid with some sort of material that is capable of keeping the sheep dry and clean. And in the *covered fold*, or what is termed *rotting*, which is in use in Herefordshire, they are sometimes formed into different divisions, so as to contain certain numbers or kinds of sheep.

They are, however, in other cases formed so as to be moveable,

moveable, either by means of wheels or other contrivances, being drawn to different situations according as they may be wanted. See *SHEEP-Houfe*.

There is likewise another fort of more imperfect sheep-fold, which is formed by the planting of trees in different methods, to as to afford the animals a fort of protection from the severity of the winter season, as well as from the excessive heats of the summer. These are termed *tree-folds*, and sometimes *plantation folds*, from the manner in which they are formed. See *TREE-Fold*.

In the construction of the second fort of sheep-folds, which were mostly formed in some distant parts of the farm, in which cases they were often denominated *standing-out folds*, a cheap and simple method was had recourse to by an excellent sheep-farmer in Suffolk (Mr. Macro). He inclosed a double fold with thirteen dozen of old hurdles seven feet long each, formed of wands, and raised a haulm fence around them, composed of upwards of sixty loads of wheat stubble, the area of the fold being littered with about thirty loads more; in this the flock were to be lodged where the field fold was unsafe, or could not be removed from place to place, on account of frost, snow, or flood; and it is stated, that he made during the same winter season, 493 loads of manure, improving at the same time the condition of his flock. The land, it is observed, lay at too great a distance to be manured from the home-stall. He likewise adds, that before he thought of this plan, his sheep were always obliged to lie in bad weather, upon a certain sheltered part of the heath, where the fold manure was not only lost to his farm, but the grass on which the dung was heaped in such quantity became so coarse and sour, that nothing would eat it; and that, exclusive of this injury, he used to lose by mortality, in a wet or severe season, during yearning time, a much greater number of both sheep and lambs, for want of the dry, warm lodging of a sheltered fold, the advantage of which he estimated at thirty or forty pounds a-year at least. He saved not less by his improved plan than thirty lambs in a year, besides sheep amounting to a greater number of lambs than he usually reared in one year during the period of his farming business.

And by the forming of these folds in any other cheap convenient manner, similar benefits may be derived by the sheep-farmer.

In all these cases the sheep should be littered down as above as often as necessary, and be well fed, twice in the day at least, with such food as has been provided, being let out during the middle of the day, except when the season is very stormy and severe. It is stated in the *Annals of Agriculture*, that one hundred and thirty-four sheep confined in this way for the period of six weeks, and littered with five loads of forty trusses each of oat-straw, forty pounds to the truss, made twenty-eight large loads of manure, consuming two acres of turnips within the time.

The great superiority of this fort of fold over that of the naked moveable kind, is therefore sufficiently obvious, and may probably be had recourse to at all seasons with some advantage. See *SHEEP*, and *FOLDING of Sheep*. Also *SHEEP-Yard*.

A sheep-fold has been lately invented by Mr. Plowman of Broome, Norfolk, upon an improved and very simple principle, combining many advantages over the old and expensive method of folding by hurdles; and as the whole fold can be removed with ease at all times, it will be found peculiarly useful in feeding off turnips on the land in frosty weather, when hurdles cannot be used. It is stated that the expense, in the first instance, will exceed that of hurdles, for the same given quantity of sheep; but having had

one in use nearly three years, he is satisfied the saving will be very considerable: for, before he adopted this method of folding, he lost from thirty to forty nights folding in the year, owing to the land being hard in dry seasons; which renders folding almost impracticable, as they never can be set without great labour and destruction of hurdles. He is also clearly of opinion, that the flock of sheep will be greatly increased when this method of folding becomes more known; and that it will enable many small farmers to keep from 50 to 100 sheep, who are now deterred from it on account of the small quantity of feed they have not answering to keep a man for that purpose only; but by this plan, they may keep a boy at 3s. or 3s. 6d. per week, who can attend on 100 or 200 sheep, and move the fold himself without any assistance. In heavy gales of wind it frequently happens that the hurdles are blown down, and the sheep of course being at liberty to range over the crops do incalculable mischief, which cannot happen with this fold. And in some counties in England, where hogs are folded, great difficulties are experienced for want of stowage, for them to feed off winter tares, &c. &c. as they root up every stake or hurdle; and having tried the experiment, he is certain this fold will keep them in, and defy their attempts to displace it. And an astonishing quantity of time is saved, as a man can remove a fold to contain 300 sheep in five minutes, which by the old method frequently takes some hours to accomplish. Many are now using folds from his model; and he received for the invention the gold medal of the Society for the Encouragement of Arts, &c.

It is further remarked, that where the fold is wanted to be used on very lilly ground, it must be begun at the top and worked down to the bottom for the ease of removing it, and then drawn up again with a horse. This, however, he has never had occasion to do, for in his land is ploughed in a contrary direction, and he works the fold in the same course as the ridges. By this means the inconvenience is avoided of crossing the furrows; and they are also a guide to keep the fold in a straight direction. With respect to the sheep getting under, he does not recollect that circumstance to have ever happened, nor does he conceive that any land, which is cultivated, can be so uneven as to admit of it.

This sheep-fold is twenty-one feet in length and three feet eleven inches in height, being composed of a top-rail, and bars below passed through uprights; the whole moving on low cast-iron wheels, and made strong, but in a light manner.

*SHEEP-Houfe*, a fort of slight wooden building, constructed for the purpose of containing and protecting sheep in bad weather, &c. Houses of this kind are usually made low, for the sake of warmth in the winter, being mostly a third part longer than they have breadth; they should also be sufficiently large for the quantity of sheep they are to contain. The sides should be lined with boards, and the bottoms be laid in an even manner with stone or some other material, that the litter may be well impregnated with the urine of the sheep. And it has been advised to have the sides exposed to the sun, set with lined moveable hurdles, that when it thaws the whole may be laid open, to afford due refreshment, and give the sheep an opportunity of feeding upon the pasture wherein they stand. They should be well and securely covered with some fort of proper material upon the tops. They are sometimes fixed in particular situations, but in other cases, which is the more improved method, to be constructed as to be capable of being removed as they may be wanted. One of the latter kind, employed on the farm of the Hon. George Villers, in Hertfordshire, which is very complete, is described, with a plate, in the *Corrected Agricultural Survey*

## SHEEP.

vey of that district, lately published by the Board of Agriculture.

In this sheep-house the wheels are fixed to the sides, being sixteen inches in diameter, and having an axle-tree to harness the horse to, with weather-boarded flaps hung with hinges, to turn up and button against the sides when it is removed. It has also folding doors to open when the sheep are let in or out, and fixed weather-boarding, with cover-boarded windows to open on hinges sideways, in order to put fodder into the racks. Likewise a canvas roof, with open railing for air.

It is observed, that the length of the building is from twenty feet to any length; the width to be such as to enable the building to pass through the field-gates; the weather-boarding and flaps to be made as thin as possible, and covered with pitch.

But how far the advantages of houses of this sort may compensate the expences of constructing and keeping them in repair, has not been fully shewn; nor has perhaps a sufficient number of trials been made to shew the benefit of confining sheep in covered houses or folds, or whether the economy of the animals is well suited to such a system. Some circumstances of advantage attending the practice of housing sheep have certainly been stated, but no satisfactory comparative experiments have, so far as we know, been made. And from the plan being little or not at all adopted in many extensive sheep districts, and in others where it once prevailed being either wholly in disuse or much on the decline, as is well known to be the case in Gloucestershire and the county of Hereford, there seems reason at least to presume that it is not so necessary or so well suited to the habits of the animal, nor even so beneficial as has been supposed by some writers on the subject. See SHEEP, and *FOLDING of Sheep*.

Houses of this nature, for the purpose of sheltering sheep and lambs in bad weather, are formed in a very cheap and simple manner in Romney-Marsh, as may be seen in Price's account of the sheep-husbandry of that district.

*SHEEP-Hurdles*, the flaps or sort of fence-gates which are set up so as to confine sheep at the time of folding them on arable land, or while they are feeding down, or upon any particular sort of food. They are of several different kinds, and either close or open; but the former are in general to be preferred, as affording the most shelter. It is obvious that the number required to inclose a certain space must depend upon the length. See HURDLE.

*SHEEP-Husbandry* or *Farming*, that sort of farm management which relates to or has sheep for its principal object. There are various modifications of this sort of farming, depending upon the differences in the circumstances of the lands, their nature and situations, as well as other local matters. See SHEEP.

It is not improbable but that in this sort of husbandry and farming, the most benefit and advantage may often be derived where there is a judicious intermixture and conjunction of other sorts of management, as those of cultivation, cattle, planting, and some others, sheep being constantly the great object. By such means advantages are afforded and brought forth in a great variety of different ways to the individuals themselves as well as the community at large.

In this sort of farming management it is of much consequence to have recourse to the fixing upon such plans and methods as are the best and most suited to the state and nature of the farms and markets for the sales of the animals. In cases where the farms are high, and of a cold exposed nature, the wether system may often enter largely into the

plan which is to be adopted. Where they are of the more mixed nature, and consist of high, as well as low lands, they may sometimes be most suitably stocked, in a partial manner, with ewes and lambs, and with wethers. In those of the more common sort, the breeding or rearing systems, according to circumstances, may frequently be the most profitable modes. And in rich grass land and mixed farms, which are provided with parks and pastures, as well as arable lands, the sheep-farmer may not unfrequently be tempted to fatten the saleable part of his sheep-stock, particularly where the markets are convenient for him in respect to distance.

In all these sorts of farms in this kind of husbandry, the breeds or kinds of sheep should always be selected and provided with a perfect consideration of their nature, and the management of the sheep be carefully directed with the same intention. The means of disposing of them should also be well regarded. Many other circumstances likewise require attention in this sort of husbandry and management. The inquirer may find much useful information on the subject of Highland sheep-farms and sheep-farming, in the third volume of the "Transactions of the Highland Society."

*SHEEP-Marks*, and *Marking*, the marks and means of performing those which are put upon sheep in different ways and manners; as by means of tar, ochre, reddle, wad, and other similar substances, and by cutting the ears of the animals in different forms and methods. These are useful and necessary to the sheep-farmer on many occasions and accounts; they serve to distinguish his particular sheep and flocks from those of others, to discriminate the several different kinds, and to point out the various sorts of management which are necessary with different kinds of sheep and lambs, as well as to answer different purposes in the sale of them, &c. In the marking with tar, a tool or contrivance having letters fixed to the end of it, is mostly made use of, the initials of the name of the farmer being most commonly employed. With the other matters different methods are taken; such as wetting and rubbing them on slates, stones, or other matters, and then marking the sheep with them in the ways that may be thought necessary. Sheep and lambs are marked by these means in many different parts, as in the faces, on the sides, the hips, and in several other places; the work being mostly done according to the fancy of the person engaged in it, or of the owner of the flock, often in different curious modes and forms, as straight lines, curves, circles, and a variety of other more out-of-the-way methods. The marking of the sheep in the ears is performed by cutting them with a sharp knife in different forms and manners; as in that of a fork, an under and upper slant, an under and upper square, an under and upper notch, a staple, an under and upper slit, straight slit, a crop, a crop and slit, a hole, a hole and slit, &c. All these several modes may be seen represented in Price's System of Romney-Marsh Sheep-grazing.

Marking sheep in the ears, in these or other methods, forms excellent and correct means of distinction, for knowing them by, in a variety of cases and circumstances in sheep-farming.

Dr. Lewis recommends the following composition for marking of sheep; *viz.* melted tallow, with so much charcoal, in fine powder, stirred into it, as is sufficient to make it of a full black colour, and of a thick consistence. This mixture, being applied warm, with a marking-iron, on pieces of flannel, quickly fixed or hardened, bore moderate rubbing, resisted the sun and rain, and yet could be washed out freely with soap, or ley, or stale urine. In order to render it still more durable, and prevent its being rubbed off, with the tallow may be melted an eighth, sixth, or fourth of its weight

## SHEEP.

weight of tar, which will readily wash out along with it from the wool. Lewis's Com. Phil. Techn. p. 361.

**SHEEP-Pens**, the divisions made by the small moveable gates or hurdles, which are set up to keep sheep in some particular situation. They are usually formed on a dry place, about the corners where different inclosures of the pasture kinds meet, so as to be convenient for the whole. They are useful in examining and selecting the sheep, being divided so as to contain about three dozen sheep each, as by this means they are always at the command of the shepherd for any purposes he may have in view. The bottoms should be firm and dry, so that the sheep may not be soiled.

Pens or coops are likewise made and used in the pounds where the ewes are lambled or put, in some sheep districts. These are usually about two feet seven or eight inches in the square, into each of which one ewe and the lamb are put, and suckled, where there is a disinclination in the ewes to let their own lambs suck, as occasionally happens, and where strange lambs are put to them. Two of the side-boards of these pens are capable of being lifted up and let down so as just to admit the ewes; in which they move with difficulty, consequently are not able to reach the lambs to beat them away; by which means they thus find an opportunity of sucking against the wills of the ewes. These pens are therefore often very convenient in these cases, two of which are mostly kept in each lambing-ground or yard. See **SHEEP-Pound**.

**SHEEP-Pound**, any sort of narrow inclosure for the confining of sheep. Pounds of this kind are of many different sorts, and useful for several different purposes in the management of sheep-flocks, as those of lambing, catching, sorting, and dressing them in different ways, &c. They sometimes occupy pretty large spaces of ground, but at other times are only of very small extent.

**SHEEP Rubbing-posts**, the small posts and pieces of wood which are fixed up in sheep-pastures for them to rub themselves against. They are sometimes simple upright posts, but at others they have cross pieces put through them. They are very necessary and useful to the animals. See **RUBBING-Post**.

**SHEEP-Shears**, the shears used in clipping or shearing of sheep. They are frequently termed wool-shears. They are made with a spring bow in the handle part, which causes them to open readily in working with them. The handle part is mostly about six inches in length, and that of the blade about five; but shears of this kind vary much in size in different places.

**SHEEP-Skin**, or *Pelt*, the common covering by which the sheep is surrounded and defended. The skins of these animals differ much in thickness, size, and other properties, according to the nature of the different breeds. Sheep pelts, or skins, sometimes form an article of great utility and profit to sheep-farmers, being sold to the fell-mongers, or other persons in their neighbourhood, under constant contracts by the year, at different prices; as from the time of shearing to Michaelmas, at from 1s. to 1s. 6d.; from that until Shrovetide, at from 2s. to 2s. 6d.; and from Shrovetide to shearing-time again, at from 3s. to 3s. 6d. Something of this method is pursued by the South Down sheep-farmers in the sale of their sheep-skins, as well as by those of several other great sheep districts, by which great advantage often arises.

**SHEEP Washing-Hooks**, the long-handled hooks which are made use of in washing sheep in some places. The hooks are in these cases fixed at the small ends of the long handles, in several different forms, as in that of somewhat the manner of an S; that of two small sorts of half circles, with a little

straight portion in the middle, to which the handle is joined, and, in short, quite straight portions. They are very useful, in some instances, in guiding and directing the sheep in this business.

**SHEEP-Yard**, any sort of inclosed yard or place in which sheep are confined and kept, either for the purpose of bringing forth their young, feeding, or fattening. These sorts of yards are now becoming pretty general in many sheep districts, as well as some other places. They are made in several different ways, according to the nature of the situation and other circumstances; and are often capable of being formed in easy, cheap, and convenient methods. See **SHEEP-Fold**, and **SHEEP-House**.

It is stated in the Agricultural Report of the County of Oxford, that at Chilton, Mrs. Latham has one of the most complete sheep-yards in it: a shed surrounds three sides of it, in which are racks and troughs for the sheep to take their food from; it is thirty-one yards in length and sixteen in breadth; the sheds being five yards broad. This sheep-yard does very well for two hundred ewes. The ewes are usually brought into the yard from four to six weeks before the lambing-time, and continued in it until that is over, going out however in the day-time. This is said to be considered as a very excellent method, but attention must be paid in it, that the dung does not accumulate, as by its fermentation the sheep are liable to be injured. It should, of course, be carted out in a repeated manner. When not removed so often as to prevent its taking on heat, it has also been found, in Essex, to prove dangerous to lambing ewes, as well as ewes and lambs.

The sheds may be raised on the sides of these yards so as to serve as fences also. Stubble, haulm, and other similar matters, may likewise be made to form warm walls as the outside fences of them.

All yards of this sort should be kept constantly well littered with suitable substances of that kind, upon foundations laid with good earth, sand, or some other proper material.

In some large sheep districts, as the South Down, in Sussex, the farmers have sometimes two or three of these yards, which are well sheltered for the sheep to lie down in at night, in very rainy and stormy weather. In some instances a yard of this nature, including the sheds, comprehends a space of not less than three hundred and fifty-five square yards; the sheds around which are about four yards wide. The whole are kept, for the mott part, thoroughly well littered down. They are commonly extremely warm, and found to preserve many lambs in bad weather. The whole of the circumference around them, in some cases, has a rack for containing hay.

In the Dorchester district of the firl of the above counties, natural grats being extremely scarce, straw is given in large quantities to sheep, as soon as ever the frosty mornings come on; barley-straw is had recourse to in these yards, or in standing pens; and afterwards bean and pea-straw, which they are very fond of: they pick off the pods and tops, and do very well with these substances. These sorts of straw are occasionally carted to the field for their use; and what they do not consume, brought back to the yards; a practice which is pursued to the saving a great many tons of hay. Such dung as is made in this way is found to be very good.

Pea may likewise be applied in these yards, or other ways, in fattening lambs, the mothers of which are at turnips. They are given in troughs, six or eight weeks after the lambs have been dropped. By the lambs having the liberty of running through the openings in the hurdles, where the field mode is followed, it is often some time before they will take to this

## SHEEP.

fort of food, but they mostly come on gradually, until a score will eat a peck a day. Peas are sometimes given in this manner, till they reach six shillings a bushel, and found to answer. A great many sorts of food of these and other kinds may be used with superior advantage for sheep in these yards, and a vast supply of good manure be provided at the same time.

**SHEEP-Clatter**, in *Rural Economy*, a term applied in some sheep districts to the person who has the care of clatting the ewes just before the lambing-time begins.

**SHEEP-Lamber**, a name given to the person who has the care and management of the ewe-flocks, which are under the state of lambing, in some sheep districts. It is of very great advantage to a sheep-farmer to have a careful, steady, active lamber, unless he attends to the business himself, which is always the best way where it can be done; as few will be found who are sufficiently attentive and diligent at this period, and, of course, much loss may be sustained. Where persons are hired for this purpose, they should, it is supposed, be rather elderly than young, as being more experienced and less apt to be hasty, as the business is intricate, tedious, and often subject to much trouble, confusion, and disorder, which stand in need of a great deal of patience to have them properly attended to and rectified. If they are, or have been lookers, it is so much the better, but this is far from being always the case, even in the principal situations where sheep are kept. In the great sheep district of Romney-Marsh, it is the custom for the lambers to have the skins of the dead lambs as a perquisite, which are usually sold at about 5s. the dozen. This is certainly a bad practice, as it tends to the making of rogues. The interest of the sheep-master and his servant, which ought to be the same, are separated, as what is the loss of the one is the gain of the other, and much injury and disappointment result from it.

In the above great district for sheep, it is usual for the lamber to go his regular rounds at four o'clock in the morning, and to continue with the ewes until about seven or eight, returning to the fields until dinner-time; then going off again at one, and returning about five; setting off on his last round at six o'clock, when he does not return until dark. There is indeed sometimes so much to do, that he cannot come home above once or twice a day: the lambing should on no account be ever left until the lamber has every thing in a fair way, especially at the time of night.

**SHEEP-Looker**, the name of the person who has the over-seeing and management of the sheep-flocks, in some districts. Persons of this kind should always be of careful, steady, active dispositions; with sufficient experience, and a full knowledge of the different modes of sheep management. See SHEPHERD.

**SHEEP Lambing-Hooks and Marks**, the instruments of the hook and mark kind, which are made use of in laying hold of the lambs, and in marking them, in particular cases and circumstances. In the former the handle is about seven feet in length, the head, or circular open part, three inches in width; the neck, or opening part to it, two inches and one-eighth wide; and the guide, or bill, six inches and a half in length. The latter have the handles about seven inches and a half long, with straight and curved or circular marks at the ends, one inch and three-eighths in length, and one inch and two-thirds in width, inside the circle. These instruments are very useful on many occasions.

**SHEEP Hay-Rack**, that sort of rack which is provided for the use of sheep in their consumption of hay and other sorts of fodder of the same nature. They are made in many different ways, as open or covered on the tops, and boarded

or barred up a little height at the bottom part, as well as raised on low wheels, or wholly without them.

They are usually from about six to nine feet in length, and about two feet and a half in height; the space for the hay at the top about one foot ten inches, but which is sometimes contracted at the bottom so as for the two sides to come nearly together, standing out in the manner of common horse racks. The openings for the sheep to feed through from three, four, or five inches to seven or eight. The smaller they are the less loss there will be, provided they are sufficient for the sheep getting at the fodder. The bars and boards put at bottom in some sorts of these racks prevent the animals getting into them. When formed with covers and screens for keeping the hay or other food, and the sheep, while feeding, from being wet; they are the most complete, especially if, at the same time, they be provided with low wheels, so as to be capable of being moved from place to place. In small racks, where wheels are put at one end, they can be easily moved about.

These racks are of very great use and convenience on all farms where sheep are kept in any quantity. See RACK.

**SHEEP Corn-Bin**, any sort of trough or bin formed for the purpose of containing the corn, or any other similar kind of food for sheep, either in fattening, or in other modes of managing them. Bins or troughs of this nature are usually contrived in a light manner, so as to be moveable on low wheels; having covers at some height over them, supported from below by the ends and upright pieces in somewhat the roof-form, so that the wet may be prevented from getting to such provisions, and the sheep enabled to feed dry. They are generally made very narrow, but of considerable length, the box or trough for the food having only the depth of a few inches.

Sheep-bins of this sort are very necessary and useful in many kinds of sheep management.

**SHEEP-Dung**, the manure afforded by sheep, which, by means of proper folding in yards properly littered with straw, stubble, &c. may, in many cases, be increased to a considerable extent, so as to render it an object with the farmer. See DUNG, FOLDING of Sheep, and MANURE.

**SHEEP-Drains**, a name sometimes given to those small drains which are frequently formed upon the more soft and damp sheep-walks and pastures in different parts of the kingdom, in order to render them in a state of greater dryness. They are often made not more than two feet in width at the surface, and one spit and the shovelling in depth. They are most suited to that sort of wetness where the bottom is of a clayey or tilly nature. Such sort of work can, in some places, often be done at three-halfpence the rood of six Scotch ells. These drains should constantly have a gentle slope or declination across the declivities of the grounds on which they are made.

**SHEEP-Farm**, that sort of farm which is principally conducted under some system of sheep management. Many situations are suited to some branch of this husbandry, which cannot be converted to the purposes of raising grain or fattening cattle, &c. See SHEEP, and FARM.

The more dry the lands are, and the more fine and short the grass is which is upon them, the better and more proper and suitable they are, in general, for the purposes of sheep-farms. Where the substratum is of a lime-stone quality, this is mostly the case, in the most favourable degree. But in many instances now, arable farms are likewise sheep-farms, to a very considerable extent; artificial food being grown and raised for the sheep-stock in sufficiently suitable proportions. There is probably much advantage in this combination in all cases in which it can be properly admitted. Sheep-

farms should constantly be formed with great attention to the nature of the grafs, the expofure, and the fhelter for the animals. They fhould alfo be kept dry and in good order on the furface, with every fort of proper convenience for the management of fheep. See *SHEEP-Hufbandry*, and *FARMING*.

*SHEEP-Leafe*, a term applied to pafture-land appropriated to the feeding or fupporting of fheep; or any fort of pafture-land on which this kind of animal or live-ftock is kept.

*SHEEP-Pafture*, that kind of dry, firm pafture land which is fuitable for the purpofes of grazing, feeding, and fattening fheep. Many forts of moift land are not at all proper for, or adapted to this ufe, though well futed for fome other forts of farm management.

*SHEEP'S-Trotters*, a refufe material procured from fell-mongers, which is made ufe of in fome places as a manure to be turned into the land. They are bought at about 6*d.* the bufhel, loofely heaped, in fome places, and coft about 2*d.* more in carriage, being ufed in the proportion of from twenty to forty bufhels the acre, being afterwards pricked in to prevent their being eaten by dogs, crows, &c. They anfwer beft on fuch lands as are rather dry, and where the feafon is rather moift. They contain a large proportion of lime, and are often adulterated by being mixed with fand, as well as oak faw-duft; which laft is faid not to injure them. Furriers' cuttings are nearly the fame, and made ufe of in a fimilar manner.

*SHEEP'S Cove*, in *Geography*, a bay on the E. coaft of Newfoundland, between Bay Robert and Port Grave.

*SHEEP Ifland*, a fmall ifland near the coaft of South Wales, E. of the entrance into Milford Haven. N. lat. 51° 38'. W. long. 5° 9'.—Alfo, a fmall ifland on the northern coaft of the county of Antrim, Ireland, oppofite to the extreme point of the head-land, between Ballintoy and Ballycaille, not far from the remarkable rock, called Carrick-a-Rede. N. lat. 55° 15'. W. long. 6° 11'.

*SHEEP-Fefcue Grafs*, in *Agriculture*, a fort of grafs which, while it has been much prated by fome as ufeful in paftures, has been condemned by others as of little importance from its fmallnefs, and being liable to be burnt up in dry feafons. It is faid to fucceed with lefs moifture than moft other forts of grafs. As forming a clofe-matted turf, where no great produce is required, it may be found a beneficial plant. See *FESTUCA ovina*, and *GRASS*.

*SHEEP-Nofe-Worms*, in *Natural Hiftory*, a fpecies of fly-worm, found in the nofes of fheep, goats, and ftags, and produced there from the egg of a large two-winged fly. The frontal finufes above the nofe in fheep, and other animals, are the places where thefe worms live, and attain their full growth. Thefe finufes are always full of a foft white matter, which furnifhes thefe worms with a proper nourifhment, and are fufficiently large for their habitation; and when they have here acquired their deftined growth, in which they are fit to undergo their changes for the fly-ftate, they leave their old habitation, and, falling to the earth, bury themfelves there; and when thefe are hatched into flies, the female, when fhe has been impregnated by the male, knows that the nofe of a fheep, or other animal, is the only place for her to deposite her eggs, in order to their coming to maturity. Mr. Valifneri, to whom the world owes fo many difcoveries in the infect clafs, is the firft who has given any true account of the origin of thefe worms. But though their true hiftory had been, till that time, unknown, the creatures themfelves were very early difcovered, and many ages fince were efteemed great medicines in epilepfies.

Vol. XXXII.

The fly, produced from this worm, has all the time of its life a very lazy difpofition, and does not like to make any ufe either of its legs or wings. Its head and corcelet together are about as long as its body, which is compofed of five rings, ftreaked on the back; a pale yellow and brown are thefe difpofed in irregular fots; the belly is of the fame colours, but they are there more regularly difpofed, for the brown here makes three lines, one in the middle, and one on each fide, and all the intermediate fpaces are yellow; the wings are nearly of the fame length with the body, and are a little inclined in their pofition, fo as to lie upon the body; they do not, however, cover it, but a naked fpace is left between them; the ailurons, or petty wings, which are found under each of the wings, are of a whitifh colour, and perfectly cover the balancers, fo that they are not to be feen without lifting up thefe.

The fly will live two months after it is firft produced, but will take no nourifhment of any kind; and poffibly it may be of the fame nature with the butterflies, which never take any food during the whole time of their living in that ftate. Reaumur Hill. Inf. vol. iv. p. 552, &c.

*SHEEP-Scabious*, in *Botany*. See *JASIONE*.

*SHEEP-Shank*, in *Sea Language*, is a fort of knot, or hitch, caft on a rope, to fhorten it as occafion requires; particularly to increafe the fweep or length of a tackle, by contracting its runner. By this contrivance the body, to which the tackle is applied, may be hoifted much higher, or removed much farther, in a fhorter time. Falconer.

Thus, if any weighty body is to be hoifted into a fhip, &c. and it be found that the blocks of the tackle meet, or *block and block*, before the object can reach the top of the fide, it will be neceffary to lower it again, or hang it by fome other method, till the runner of the tackle be fheep-shanked, by which the blocks will again be feparated to a competent diftance. See *RIGGING*, *Plate 1. fig. 16*.

*SHEEPCADE*, in *Agriculture*, a name provincially applied to the large fheep-houfe.

*SHEEPENT*, or *SHEEPS-COT*, in *Geography*, a river of America, in the diftrict of Maine, which runs into the fea. N. lat. 43° 43'. W. long. 69° 38'.

*SHEEPHAVEN*, a harbour on the northern coaft of the county of Donegal, Ireland, fituated weft of the Mulroy, and feparated from it by a long, and, in fome parts, very narrow peninfula. The furrrounding country is mountainous, and thinly inhabited; nor is there any town of confequence in the neighbourhood. Dunfanaghy, near Hornhead, is no more than a village, though ruins near it feem to indicate that it was formerly much larger. The filiceous fand found in this diftrict is of excellent quality for making glafs, and it is carried to Belfast for that purpofe. Under the article *HORNHEAD*, a promontory which forms the weftern boundary of the harbour, we noticed, on the authority of the late Dr. William Hamilton, in the *Transactions of the Royal Irish Academy*, the effect of drifting lands in overwhelming the veftiges of cultivation; and the change thus produced in the appearance of a country. A fimilar effect took place on the eaftern fide, which is thus defcribed by the fame writer. "About a century ago, an elegant edifice, according to the tale of that age, was built on the peninfula, between the harbours of Sheephaven and Mulroy, which at prefent ftands like Tadmor of the East, the folitary wonder of a furrrounding defert." The gardens are totally denuded of trees and fhubs by the fury of the weftern winds: their walls, unable to fuffain the mats of overbearing fands, have bent before the accumulated prefure, and, overthrown in numberlefs places, have given free

passage to this restless enemy of all fertility. The courts, the flights of steps, the terraces, are all involved in equal ruin; and their limits only discoverable by tops of embattled walls, visible amid hills of sand. The mansion itself, yielding to the unconquerable fury of the tempest, approaches fast to destruction: the freighted whirlwind howling through every avenue and crevice, bears incessantly along its drifted burden, which has already filled the lower apartments of the building, and begins now to rise above the once elevated thresholds. Fields, fences, villages, involved in common desolation, are reduced to one undistinguishable scene of sterile uniformity, and twelve hundred acres of land are said thus to have been buried, within a short period, in irrecoverable ruin." N. lat. 55° 12'. W. long. 7° 45'. Transactions of the Irish Academy, vol. vi.

**SHEEPS CUT**, a river of the United States, which joins the Kennebeck E. of its mouth, and is navigable 20 or 30 miles. On the W. side of this river is the excellent port of Wiscasset.

**SHEEPS HEAD**, a cape on the S. coast of Ireland, between Bantry bay and Dunmannus bay. N. lat. 51° 29'. W. long. 9° 45'.

**SHEER**, a town of Candahar; 40 miles W. of Ghizni.

**SHEER**, in *Agriculture*, a term used to signify pure, clean, unmixed, as in the case of grain-seeds, and many kinds of substances.

**SHEER**, in *Ship-Building*, the fore and aft curve or hang of a ship's sides or deck.

**SHEER-Draught**, the plan of elevation of a ship, on which is described the out-boards works, as the sheer-rails, wales, ports, driifts, head, quarter, post, and stern, &c. The hang or sheer of each deck inside, the height of the water-lines, &c. See **SHIP-BUILDING**, *Plate I.*

**SHEER-Hooks**, are large iron hooks used when a ship designs to board another.

**SHEER-Hulk**, is an old ship of war of 74 guns, cut down to the lower deck, or nearly so, and fitted in the following manner, to fix or take out the lower masts of ships in the royal navy, as occasion requires. It has a mast fixed in midships, about 33 inches in diameter, and 108 feet high, supported by shores, the upper shore 87, and the lower shore 81 feet long, and each 19 inches in diameter, their heels resting against the inside, abreast the heels of the sheers, which are three in number, each composed of two pieces, 22 inches diameter, scarfed together in the middle, to make 116 feet in height. The heels rest upon the outside, abreast the mast; the heads unite, and are firmly woolded together, and incline outwards, to hang over the vessel whose masts are to be fixed or taken out. The sheers are likewise supported by a derrick, which is 100 feet long, and 22 inches in diameter. The mast is further secured by shrouds and stays, and the sheers by stays and large tackles, from the mast to each sheer. From the head of the sheers depend two large tackles, by which the largest masts are raised or lowered: the effort of these tackles is produced by two capsterns, fixed on the hulk's deck for this purpose. There is also a less-sized tackle for masting small vessels. See **HULK**.

**SHEER-Rails**. See **RAIL**.

**SHEER-Strake**, the upper strake or strakes on the topside in midships. It forms the chief strength of the topside, and is therefore thicker, and continued the whole length parallel to the top timber-line and scarfs at the butts between the driifts.

**SHEER-Wales**, those strakes of thick stuff in the topside of three-decked ships, which are wrought between the

middle and lower deck ports. Sometimes they are called *middle-wales*.

**SHEER-Water**, in *Ornithology*. See **SHEAR-Water**.

**SHEER-BUCKS**, in *Geography*, a town of Persia, in Khorassan; 30 miles S.E. of Herat.

**SHEERGOTTY**, a town of Hindoostan, in Bahar; 68 miles S.S.W. of Patna. N. lat. 24° 30'. E. long. 84° 56'.

**SHEERGUR**, a town of Hindoostan, in Malwa; 30 miles N.W. of Ragoogur. N. lat. 24° 40'. E. long. 77°.—Also, a town of Hindoostan, in the circar of Gohud; 5 miles E. of Narwa.

**SHEERING**, or **SHEARING**, in the *Woollen Manufactures*, the cloth-worker or sheerman's craft, or office; or the cutting off, with large sheers, the too long and superfluous knap, or snag, found on the surface of woollen stuffs, fustians, cottons, &c. in order to make them more smooth and even.

Stuffs are shorn more or fewer times, according to their quality and fineness.

Some use the phrase *sheering of hats*, for the passing of hats made of wool over the flame of a clear fire made of straw, or spray, to take off the long hairs: others call this *flaming*, and others *singing*. Other hats, as castors, femicastors, &c. are shorn, by rubbing them over with pumice-stone. See **HAT**.

**SHEERING**, or *Sheering*, in *Sea Language*, a term used for the motion of a ship, when she deviates from the line of the course, either to the right or left, so as to form a crooked and irregular path through the water, either by reason that she is not steered steadily, or on account of the swift running of the tide, &c. in which case she is said to sheer, or go a sheering. Hence, to *sheer off*, is to remove to a greater distance.

When she lies at anchor, near port, &c. by reason of the swift running of the tide-gate, &c. she is often said to be in danger of *sheering home her anchor*, or *sheering ashore*. See **CHEST-Rope**.

**SHEER MOHAMMED PETT**, in *Geography*, a town of Hindoostan, in the circar of Condapilly, on the borders of Golconda; 21 miles W.N.W. of Condapilly.

**SHEERNESS**, a sea-port and market-town in the Isle of Sheppey, and county of Kent, England, is seated at the mouth of the river Medway, and has derived its origin and importance from this circumstance. In the reign of king Charles II. it was deemed advisable to form a fort here, to protect the entrance to the river; and in 1667 that monarch, with an engineer and other officers, surveyed this spot, and strengthened the works. The Dutch, however, sent a fleet to this point, destroyed the fortifications, and sailed up the Medway, as far as Upnor castle. After returning again from this enterprise, the government directed some strong works to be formed here, because the spot was deemed of great importance. A regular fortress was soon constructed, and mounted with a line of large and heavy cannon: and at the same time several smaller forts were built at different stations on the banks of the river. Since that time Sheerness has progressively been augmented and strengthened by new works, and now constitutes a regular garrison. It is commanded by a governor, lieutenant-governor, a fort-major, and inferior officers: and the ordnance establishment is under the controul of a store-keeper, a clerk of the cheque, and a clerk of the survey. Adjoining the fort is the king's yard or dock, which has been made subsequent to the former. This yard is chiefly used for the repair of ships that have been slightly damaged, and for building frigates and smaller vessels. A resident commissi-

tioner, with two clerks, a master-shipwright, and other officers, with labourers, are stationed here.

A modern chapel has been erected at the expence of government; but in ecclesiastical rites and privileges this is subordinate to the parish church of Mifler. According to the population reports of 1811, Sheerness was returned to contain 134 inhabited houses, and 96 uninhabited; and the inhabitants, including the convicts in the hulks, and independent of the garrison, were estimated at 1685. The hulls of the ships, called *break-waters*, are occupied by about seventy or eighty families, and altogether present a very singular appearance, the chimneys being raised of brick from the lower gun-decks. The market-day at Sheerness is Saturday, weekly.

For a long period, the garrison and inhabitants of Sheerness experienced a scarcity of fresh water, the chief supply being brought in vessels from Chatham; but it was determined by the Board of Ordnance, that an attempt should be made to sink a well within the fort; and the execution of this was entrusted to sir Thomas Hyde Page, an able engineer, whose skill and perseverance were found fully equal to the trust that had been reposed in him. The preparation of the materials, and the boring, to ascertain the different strata, were begun in April, 1781; and the sinking of the well was commenced in June following. The land-springs, &c. which greatly interrupted the progress of the work during the first 100 or 150 feet, were excluded by regularly stemming the inside of the well; till, at length, the workmen came to an immense stratum of chalk, which prevented the further necessity of stemming, and enabled them to proceed with less inconvenience. They went on, however, with great caution; and having dug to the vast depth of 328 feet, the auger with which they were trying the strata dropt down, and the water rushed up with such velocity, that the workmen could hardly be drawn out with sufficient haste to escape drowning. In six hours it rose 189 feet, and in a few days was within eight feet of the top; and has ever since produced a never-failing supply; for, though constantly drawn from, it has never been lowered more than 200 feet. The quality of the water is fine and soft, and its temperature is somewhat warmer than commonly happens in other wells. From this well, conjointly with that of Queenborough, not only the garrison and inhabitants are supplied, but also the shipping which lie at anchor at the entrance of the Medway. (See QUEENBOROUGH.) Hasted's History, &c. of the County of Kent, fol. 1. 8vo. edit. Canterbury, 1798. Beauties of England and Wales, vol. vii. by E. W. Brayley, 8vo. 1806.

SHEERPOUR, a town of Hindoostan, in Bahar; 43 miles S.S.W. of Patna. N. lat. 24° 55'. E. long. 85° 10'.—Also, a town of Hindoostan; 30 miles E. of Delhi.—Also, a town of Hindoostan, in Mewat; 25 miles N.E. of Dig.

SHEERS, in *Ship-Building*, are two masts or spars, set across at the upper end of each other, and there lashed together with tackles depending from the intersection; and they are kept upright by guys extending each way from the heads. The heels are spread and lashed, or cleated, to prevent their slipping. By this contrivance very heavy bodies are raised, such as the stem, stern-frame, and the frame-timbers of ships: like-wise ships are masted by sheers, or have their masts taken out where there is no sheer-hulk.

SHEET, in the *Mance*. See CAPARISON.

SHEET, in *Sea Language*, a rope fastened to one or both the lower corners of a sail, to extend and retain it in a particular station. When a ship sails with a lateral wind, the lower corner of the main and fore-sail are fastened by a

tack and a sheet; the former being to windward, and the latter to leeward; the tack, however, is entirely disused with a stern wind, whereas the sail is never spread without the assistance of one or both of the sheets. The stay-sails and fludding-sails have only one tack, and one sheet each; the stay-sail tacks are always fastened forward, and the sheet drawn aft; but the fludding-sail tack draws the under clew of the sail to the extremity of the boom, whereas the sheet is employed to extend the innell. Falconer. See SHEETS.

SHEET, *To hale home the*. See HOME.

SHEET-Anchor. See ANCHOR.

SHEET-Nails. See NAIL.

SHEET-Stopper. See STOPPER.

SHEETING, a term signifying the flooring of jointed planks, under the lock-gates of a canal, and at the tail of every lock and sluice, &c.

SHEFFIELD, JOHN, in *Biography*, duke of Buckinghamshire, son of the earl of Mulgrave, was born in the year 1649. At the death of his father he succeeded to his title: this was in the year 1658. At an early age he dismissed his governor, but supplying the want by his own industry, he acquired a considerable proficiency in literature. His martial ardour broke out at the age of seventeen, when he engaged in the first Dutch war as a volunteer. The indications which he gave of the love of pleasure, united with literary talents, which had a peculiar value in the reign of Charles II. rendered him a favourite at court, and he materially assisted in the obtaining for Dryden the appointment to the post of laureat. At the commencement of the second Dutch war, he was a volunteer in the fleet commanded by the duke of York, and was present at the battle of Solebay, in which he behaved with so much gallantry, that on his return he was made captain of a second-rate ship of war. In the following year he was appointed colonel of a regiment of foot under general Schomberg. In 1674 he was decorated with the order of the Garter. He was, in 1679, appointed lord-lieutenant of Yorkshire, and governor of Hull, in which year he wrote a piece, entitled "The Character of a Tory, in answer to that of a Trimmer." In this we have an avowal of his political principles, which were those of the party in whose name he wrote, and to which he adhered during life. In 1680 he went out with a force to the relief of Tangier, then invested by the Moors. In this expedition he completely succeeded, and with it ended the military services of lord Mulgrave. On the accession of James II. he was chosen of the privy-council, and made lord-chamberlain of the household. He returned these favours by a zealous attachment to his master, which led him to take a part in the ecclesiastical commission; but in this he opposed those measures of the priests which brought on the speedy ruin of that infatuated prince. Though inimical to the revolution, yet he voted for the conjunct sovereignty of king William with Mary. In 1694 he was made marquis of Normanby; notwithstanding this, and his admission into the cabinet, with a pension, yet he still had a great dislike to the king. On the accession, however, of queen Anne, his former attachment to the court was revived, and he experienced her favour by an appointment to the privy-council, and by other honours, which were terminated in 1703, by a nomination to the dukedom of Buckinghamshire. Jealous of the influence of the duke of Marlborough, he resigned the office of privy-council, and remained out of office several years, during which he built the house in St. James's park, which has, during this reign, been the principal residence of the queen. At the great change of the ministry in 1710, he was again introduced, first as steward of the house-

household, and then as president of the council. After the death of queen Anne he was an opponent of the court, and employed his time chiefly in literary pursuits, till his death, in 1721.

The duke had been thrice married, and each time to a widow: his last wife was a natural daughter of James II., by whom he had a son that survived him. Following the example of the court of Charles II., he freely indulged in licentious amours; nevertheless, it has been said that he had occasionally serious thoughts of religion, though probably not restricted to any particular party. The following is the epitaph which he composed for himself: "Dabius fed non improbus vixi: incertus morior, sed inturbatus: humanum est nescire et errare. Christum adveneror: Deo confido omnipotenti, benevolentissimo: Ens entium miserere mei." This was inscribed on his magnificent monument in Westminster Abbey, with the exception of the clause respecting Christ, which bishop Atterbury rejected, thinking simple veneration a derogatory expression applied to the second person in the Trinity.

In the capacity of poet, the duke of Buckinghamshire does not rank very high; his compositions are on a variety of topics, of which, however, the chief is "An Essay on Poetry," which, according to Dr. Johnson, contains judicious precepts, which are sometimes new, and often happily expressed, but with many weak lines, and some strange instances of negligence. In his "Essay on Satire," he is supposed to have been assisted by Dryden, who, for some peculiarities in it, had the misfortune to be taken as the real author.

The duke of Buckinghamshire composed two tragedies, entitled "Julius Cæsar," and the "Death of Brutus;" for the latter of which, at his request, Pope wrote two chorusses: of these Warburton says, that they have the usual effect of ill-placed ornaments, they make the meanness of the piece more conspicuous. In the collection of the duke's works are likewise historical memoirs, speeches, essays, &c.

SHEFFIELD, or *Sheaf*, in *Geography*, a large and populous market and manufacturing town in the south division of the wapentake of Strafford and Tickhill, liberty of Hallamshire, West Riding of Yorkshire, England, is situated at the distance of 36 miles S. from Leeds, and 162 N.N.W. from London. The origin and remote history of this town are totally unknown. In the 13th century it was noted as a staple for articles of iron manufacture. Chaucer, who wrote in the reign of Edward III., mentions the "Sheffield Whittle" in one of his poems. At that period it was likewise distinguished by a strong castle, which stood at the north-east of the town, and is said to have been built during the sovereignty of Henry III. This castle descended from the Lovetosts to the Nevils, lords Furnival, and passed from them to the Talbots, earls of Shrewsbury, and subsequently to the Howards, dukes of Norfolk, in whose family the lordship of the manor is still veiled. During the civil wars between Charles I. and his parliament, Sheffield castle sustained a long siege in the cause of royalty, but eventually surrendered upon honourable terms, on the 10th of August, 1644, and was soon afterwards ordered to be demolished, which seems to have been done most effectually, as scarcely a vestige of it can now be discovered.

Though Sheffield, as already said, was considered as a staple for iron manufactures at a very early period, its trade, for several centuries, was comparatively confined and precarious, and consisted almost entirely in the making of sheath-knives, scissors, sickles, and scythes. About the commencement of the 17th century, an ordinary kind of tobacco-box of iron, and Jews' harps, began to be manufactured here;

and in 1625 the mallet manufacturers were first incorporated by the style of "The Company of Cutlers of Hallamshire." This corporation is governed by a master, elected annually, six searchers, and twenty-four assistants, and is the only body corporate yet existing in Sheffield. It was not, however, till after the year 1750, that this town assumed the rank it now holds in manufacturing opulence. Previously to that period, none of the manufacturers had extended their traffic beyond the limits of Great Britain; but in the same year Mr. Joseph Broadbent opened a direct trade with the continent; and in 1751, the river Don having been rendered navigable to within three miles of the town, that facility was given to exportation, which has since proved so beneficial to its manufacturing interests. Soon afterwards Mr. Thomas Bolfover began to plate brass and copper buttons with silver; and in 1758 the silver plated manufacture was commenced on an extensive scale by Mr. Joseph Hancock, and has subsequently been prosecuted with great advantage by a numerous class of individuals. The opulence and population of the town increased from that time with great rapidity, and soon gave rise to numerous conveniences and improvements, both useful and ornamental. In 1760, the first stage-coach started from Sheffield for London; and in 1762, the theatre and assembly-room were built by subscription. In 1770, the first bank in Sheffield was opened by Mr. Roebuck; and in 1786, the new market-place was formed, about the same time that Messrs. Proctors erected the first steam-engine grinding-wheel. In 1793, hackney coaches were introduced; and in the same year also was laid the foundation of the General Infirmary. These circumstances are mentioned, because they are calculated to display the progressive benefits resulting from successful industry and ingenuity, the contemplation of which can scarcely fail to excite pleasurable emotions in every breast.

To notice particularly the various articles manufactured at Sheffield of late years, would occupy too considerable a space to admit of the attempt. The two great divisions of them are into cutlery and plated goods, each of which branch out into numerous ramifications. The manufacture of the latter is almost entirely confined to the town, and comprehends a great diversity of articles: such as tea-urns, coffee-pots, taskards, cups, candlesticks, and other pieces of table furniture. The cutlery division embraces the making of edge-tools, combs, cases, buttons, fenders, files, anvils, joiners' tools, lancets, forks, hafts, ink-stands, nails, knives of every description, scissors, scythes, sickles, awl-blades, bellows, &c. to which we shall only further add the refining of steel. Many of these manufactures are carried on in the country, as well as in the town, especially in the villages and hamlets of Altermcliffe, Bentgreen, Brightside, Butterthwaite, Carbrooke, Darnal, Dylon-Holmes, Dungworth, Ecclesfield, Greenoside, Grimesthorpe, Hallam, Miln-houses, Newfield-Green, Owlerton, Pittsmoor, Stannington, Sbieregreen, Upper-Heeley, Wadley, Woodseats, &c.; all of which are situated within seven miles of Sheffield. Besides the above manufactures, there are in the town and its vicinity several extensive founderies for iron, brass, and white metal.

Sheffield occupies a fine eminence at the confluence of two rivers, the Sheaf, whence the name of the town is derived, and the Don. In former times the houses were entirely built of stone; but for the last century they have been chiefly composed of brick. There are few towns which surpass it in the regularity of its streets, many of them running in a direct line, and displaying a series of uniform and respectable edifices. Sheffield extends about a mile

a mile in length, from north to south, and nearly as much in breadth, from east to west. According to the population census of 1811, it contains 7927 houses, and 35,840 inhabitants, being an increase of 4526 persons since 1801, the date of the preceding report, notwithstanding the retardation its manufacturing prosperity has sustained during that eventful period. According to Gosling's plan of the town, made in 1732, there were 32 streets in Sheffield at that time: in 1771 these were increased by 25 new streets; and in 1792, seventeen additional streets had been made.

Sheffield is not particularly distinguished by the superiority of its public buildings, which are rather calculated for purposes of utility than for show. The principal of them are the Town-hall, built in 1700, Cutlers'-hall, the General Infirmary, the assembly-room, and theatre, and four churches belonging to the establishment. Neither the Town-hall nor Cutlers'-hall deserve attention as architectural productions; but the infirmary and theatre are handsome structures. The former, commenced in 1793, stands on the west side of the town; and in respect of situation, plan, medical aid, and comfortable treatment, may vie with almost any similar institution in Great Britain. The latter, which occupies the same building with the assembly-room, stands in Norfolk-street. The four churches are Trinity church, St. Paul's, St. James's, and a chapel belonging to the duke of Norfolk's hospital. Trinity church, anciently called St. Peter's, is the parish church of Sheffield, and appears to have been erected as early as the reign of Henry I. On the south side of the chancel is the Shrewsbury chapel, which contains four monuments to the memory of the earls of Shrewsbury of the family of Talbot: and on the north side is a monument commemorating judge Jeffop of Broom-hall, and his lady. At the entrance to the same division of the church are deposited the remains of William Walker, of Darul, in this parish, who is said to have been the executioner of Charles I. Besides the above churches, Sheffield contains seven meeting-houses for Protestant dissenters, one for Unitarians, two for Methodists, one for Quakers, and a Roman Catholic chapel.

The duke of Norfolk's hospital, mentioned above, stands on the eastern bank of the Sheaf. It was founded and endowed in 1670, by Henry, earl of Norwich, and received a considerable accession of property by Edward, duke of Norfolk, in 1770. The building consists of two quadrangles, each containing eighteen dwellings, for the accommodation of eighteen men, and the same number of women, all of whom receive five shillings a-week, with clothing and coals. Here is also an hospital founded by Mr. Thomas Hollis, a merchant of London, in 1703, for poor cutlers' widows; likewise a free grammar-school, and two charity-schools; one for boys, and another for girls.

The other objects of a public kind which remain to be noticed are, the military barracks, situated at the north-eastern extremity of the town; and the bridges thrown over the Sheaf and the Don. That upon the latter river is called Lady's bridge, from a religious house, which formerly stood near it, and was dedicated to the Virgin Mary. It was built in 1485, but underwent great alterations and improvements in 1762.

Sheffield has two market days, weekly, Tuesday and Saturday; the first for corn, &c. and the second for butchers' meat. There are also fish-markets on Monday and Thursday, and two annual fairs, one on the first Tuesday after Whitfun week, and another on the 28th of November. A new market-place, with extensive and commodious shambles and other conveniences, was formed and finished here Aug. 31, 1786. Sheffield supports a weekly

newspaper, called the "Iris," which is edited by Mr. James Montgomery, the author of "The World before the Flood," and other interesting poems.

The scenery in the vicinity of this town may be characterized as romantic. It is surrounded by lofty hills, commanding fine views over a populous and variegated country. At the distance of about a mile and a half to the eastward, stand the ruins of Sheffield manor-house, the ancient seat of the earls of Shrewsbury, where cardinal Wolsey was seized with the disease which terminated his life about a week afterwards, at the abbey of Leicester. Wharfedale park, the seat of the honourable James Archibald Stuart Wortley, situated on the river Don, six miles to the north-west of Sheffield, is equally remarkable for the elegance of its mansion, and the beauty of the surrounding grounds. In the neighbourhood of Sheffield are some alum mines; and at Wickersley, near the town, is a quarry, which supplies the manufacturers with grind-stones for the finer articles of cutlery. Aikin's Description of the Country round Manchester, 4to. 1795. Magna Britannia, 4to. 1703. Camden's Britannia, fol. edit. 1789. Beauties of England and Wales, vol. xvi. by John Bigland, 8vo. 1812. Gentleman's Magazine, April and September, 1764.

SHEFFIELD, a town of America, in the state of Vermont, and county of Caledonia, containing 455 inhabitants.—Also, a town of the state of Massachusetts, in the county of Berkshire; incorporated in 1733, and containing 2439 inhabitants. It is traversed by Housatonic river, which supplies water for several mills and river-works. South mountain extends along the whole length of the town, on the E. side of the river.

SHEFFIELDIA, in *Botany*, Forst. Gen. t. 9, was so called by Forster in honour of the Rev. Mr. Sheffield, whom he designates as the chief botanist at Oxford. This gentleman was, we believe, one of the companions of the illustrious Banks, in the early part of his studies, and retained to the last a love of the science, though without having materially contributed to its advancement. He was living as a fellow of a college, at rather an advanced age, in 1788. The genus in question is now sunk in *SAMOLUS*; see that article.

SHEFFORD, in *Geography*, a market-town in the parish of Compton, hundred of Clifton, and county of Bedford, England, is situated at the distance of 10 miles S.E. from Bedford, and 41 miles N.N.W. from London. It was formerly a place of much more importance than at present, and had a large weekly market on Friday, which has now become almost nominal. Still, however, it possesses the advantages arising from four annual fairs, held on the 23d of January, Easter Monday, the 19th of May, and the 10th of October. The two first usually afford a large supply of sheep and cows; the third is less important; and the fourth is now only a holiday fair. Shefford is a chapelry, having distinct officers of its own, and maintaining its own poor. Here is a Roman Catholic chapel, endowed with an annual stipend left in trust for that purpose. According to the parliamentary returns of 1811, this town contained 123 houses and 536 inhabitants.

In the parish of Finton, and at the distance of about four miles from Shefford, is Wrest Park, the seat of baroness Lucas, a representative of the family of the Greys, earls and dukes of Kent. In its present state the house retains little appearance of antiquity, having been at various times altered and modernized. It contains a large collection of portraits, forming nearly a complete series of all the members of the noble family just mentioned, from Henry, earl of Kent, one of the peers who sat on the trial of Mary, queen

queen of Scots, down to the present time. Here are likewise several portraits of the Crew family, and others; among which are Sir Rauldolph Crew, lord chief justice of the court of king's bench; a fine picture of Thomas lord Crew, by Sir Peter Lely; Nathaniel lord Crew, bishop of Durham; and the late lord chancellor Hardwicke.

The garden attached to this mansion exhibits a specimen of the old style of arrangement and ornament, modified and improved by the celebrated Brown, who formed the serpentine canal, which nearly surrounds the garden, and is supplied by a spring rising near the house. At the spring-head is a cold bath, over which is a building, designed by Sir William Chambers, in imitation of a Roman temple. The late duke of Kent, who was very partial to this residence, adorned the gardens with obelisks, and other buildings, particularly a magnificent banquetting house, which terminates a spacious avenue in front of the house. Lyfons's *Magna Britannia*, Bedfordshire, 4to. 1806. *Beauties of England and Wales*, vol. i. by John Britton and E. W. Brayley, 8vo. 1803.

**SHEFNAL.** See **SHIFFNAL.**

**SHEHERON**, a town of Persia, in the province of Irak; 15 miles E. of Kermanshaw.

**SHEHERVERD**, a town of Persia, in the province of Irak; 30 miles S.W. of Sultania.

**SHEHOUN**, a town of Syria, under the jurisdiction of an independent aga, anciently called "Cappareas;" 18 miles N. of Hamah.

**SHEHRBAN**, or **SHEREBAN**, a town of the Arabian Irak, on the Diala; 50 miles N. of Bagdad. N. lat.  $34^{\circ} 8'$ . E. long.  $44^{\circ} 5'$ .

**SHEHRIGHERD**, a town of Persia, in the province of Irak; 33 miles W.S.W. of Kom.

**SHEHRISTAN**, a town of Persia, in Khorassan; 210 miles W. of Herat. N. lat.  $35^{\circ} 10'$ . E. long.  $56^{\circ} 20'$ .—**Alfo**, a town of Persia, in the province of Chuzistan, or Kuzistan; 50 miles N.W. of Schiras.

**SHEIB**, a lake of Egypt; 48 miles E.N.E. of Cairo.

**SHEIDEK**, a mountain of Switzerland, in the S.E. part of the canton of Berne; 10 miles S.E. of Interlacken.

**SHEIK**, or **SCHEIK**, in the *Oriental Customs*, the person who has the care of the mosques in Egypt: his duty is the same as that of the imams at Constantinople. There are more or fewer of these to every mosque, according to its size or revenues. One of these is head over the rest, and answers to a parish-priest with us, and has under him, in large mosques, the readers and people who cry out to go to prayers; but in small mosques the sheik is obliged to do all this himself. In such it is their business to open the mosque, to cry to prayers, and to begin their short devotions at the head of the congregation, who stand rank and file in great order, and make all their motions together. Every Friday the sheik makes an harangue to his congregation. Pococke's *Egypt*, p. 171.

**ШЕИК-Беллет**, the name of an officer in the Oriental nations.

In Egypt the sheik bellet is the head of a city, and is appointed by the pacha. The business of this officer is to take care that no innovation be made, which may be prejudicial to the Porte, and that they send no orders which may hurt the liberties of the people. But all his authority depends on his credit and interest, not his office: for the government of Egypt is of such a kind, that often the people of the least power by their posts have the greatest influence; and a caia of the janizaries, or Arabs, and sometimes one of their meanest officers, an oda-basha, finds means,

by his parts and abilities, to govern all things. Pococke's *Egypt*, p. 161.

**SHEIKHAUT**, in *Geography*, a town of Bengal; 8 miles N. of Islamabad.

**SHEIKH-UL-JEBAL**, *Dominions of*, or lord of the mountains (commonly called the old man of the mountain) comprised the whole of that elevated tract in the province of Azerbajan in the Persian empire, which runs parallel with the course of the Kizilozzin and the greater part of Gilan. When destroyed by Holaku, the Houlaines, or Assassins, possessed upwards of 100 strong holds; but the residence of the prince was generally confined to the castles Roudbar and Allah Ahmout, both of which are situated in the Kohr Caucausan, near Kazween.

**SHEIKPOUR**, a town of Hindoostan, in Bahar; 28 miles E. of Bahar. N. lat.  $25^{\circ} 9'$ . E. long.  $86^{\circ} 3'$ .

**SHEIMERS**, a town of New Jersey; 34 miles N.W. of Morristown.

**SHEK ABADE'**, a town of Egypt, anciently called *Antinoë*; 8 miles N. of Abu Girgè.

**SHEK Abdalla**, a village of Syria, in the pachalic of Aleppo, where are some springs of water; 20 miles S.E. of Aleppo.

**SHEK Abu Ennur**, a town of Egypt; 7 miles S. of Benisuef.

**SHEK Ammer**, a town of Egypt, situated on the Nile; 17 miles N. of Syene.

**SHEK Embade**, a town of Egypt, on the right bank of the Nile; 16 miles S.S.E. of Girgè.

**SHEK Eredi**, or *Haradi*, a town of Egypt, on the E. side of the Nile. Here is the tomb of a Turkish saint, who after his death is said to have been metamorphosed into a serpent, which never dies, and is consulted as a physician; 8 miles N.N.E. of Achmim.

**SHEK il Etman**, a town of Egypt, on the Nile; 7 miles S.S.W. of Cairo.

**SHEK Fadlé**, a town of Egypt, on the right bank of the Nile; 10 miles S. of Abu Girgè.

**SHEK Zeineddin**, a town of Egypt, on the left bank of the Nile; 3 miles N. of Tahta.

**SHEKEL**, *SHEKLE*, *Sheckle*, an ancient Hebrew silver coin, which was originally a didrachm, but, after the Maccabees, about the value of the Greek tetradrachm, or four Attic drachmas, or four Roman denarii, allowing the drachma and denarius to be of the same value; and, according to Mr. Raper's valuation of the drachma at  $9^d.286$ , equal to  $37^d.144$ . See **DENARIUS** and **DRACHM**.

In the Bible, the shekel is sometimes also rendered *solidus*, and sometimes *stater*.

The Jewish doctors are in great doubt about the weight of the shekel; and it is only by conjecture, and by the weight of the modern shekel, that the ancient one is judged equal to four Attic drachmas.

Father Souciet has described several of these shekels in his Dissertation on the Hebrew Medals. By the way he observes, that the third and fourth parts of a shekel, described by Waferus, de Ant. Numb. Heb. are counterfeits of that author.

The Hebrew shekel, according to F. Merfenne, weighs 268 grains, and is composed of 20 oboli, each obolus weighing 16 grains of wheat. This, he says, is the just weight, as he found by weighing one in the French king's cabinet. He adds, that such as come short of this weight have been filed or clipped. Bishop Cumberland tells us, he has weighed several, and always found them near the weight of a Roman semuncia, or half ounce. Mr. Raper infers from various considerations (see **DRACHM**), that the

mean didrachm, of 133 troy grains, must be very near its just weight, and its half, or  $66\frac{1}{2}$  grains, that of the Attic drachm. The weight of the shekel would therefore be  $66\frac{1}{2} \times 4 = 266$  troy grains.

Some are of opinion, that the Hebrews had two kinds of shekels, the *common*, or *profane* shekel, called *didrachma*; and the shekel of the *sanctuary*; which last they will have to be double the former. By this expedient they think we may get clear of some difficulties occurring in Scripture, where things are mentioned as of incredible weight; particularly that passage where it is said, that every time Abfalom cut off his hair, the weight of which used to incommode him, he cut off the weight of two hundred shekels.

But Villalpandus will not hear of such a distinction; nor do bishop Cumberland, M. Morin, Greaves, &c. take the opinion to have any foundation. The *profane* shekel, or shekel of four drachmas, they agree, was the same with the *sacred* shekel; and it was only called by this last name, because the standard of it was kept in the sanctuary by the priests.

Greaves apprehends, that the *τριξοντα αργυρια*, or 30 pieces of silver, which were given to Judas, as the reward of his treason, were 30 shekels. Some modern writers, he says, imagine they were 30 denaris, and others, that they were *triginta librae*, or *triginta talenta*. Greaves's Works, vol. i. p. 257, note n.

It is maintained by several, that the Jews had also a *gold* shekel, *felus aureus*, of the same weight with the silver one; and valued at 1*l.* 16*s.* 6*d.* sterling.

The shekel is supposed to have been first struck in the Desert, on the footing of 100 to the Attic mina, weighing 160 grains of wheat, and current for 10 geratis, or obols; but that afterwards they were struck of double that weight.

Some will have the shekel to be the oldest piece of money in the world, as being in use in Abraham's time; but this was not coined, or stamped, nor had any other value besides its intrinsic worth.

Xenophon mentions shekels as current in Arabia; and Du-Roi speaks of others struck and current in England.

Pinkerton, in his Essay on Medals, (vol. i. p. 291.) suggests, that the Hebrew shekel, and also the brass coins, with Samaritan characters, were not most of them later than the Christian era, and generally the fabrications of modern Jews. At any rate, the same impression of a sprig on one side, and a vase upon the other, runs through all the coins of that barbarous nation; and the admission of but one of them is rightly esteemed to be almost a disgrace to a cabinet.

SHEKIDJEK, in *Geography*, a town of Grand Bucharja; 60 miles N.W. of Sagarian.

SHEKOABAD, a town of Hindoostan, in Doonab; 60 miles W. of Canoge. N. lat.  $27^{\circ} 9'$ . E. long.  $79^{\circ} 2'$ .

SHELAH, a town of Asiatic Turkey, in Natolia, near the Black sea; 12 miles N. of Himid.

SHELAN, a town of Persia, in the province of Farsistan, near the Persian gulf; 75 miles S.S.W. of Jarom.

SHELBURN, a town of America, in the province of Vermont, and county of Chittenden, on the E. side of lake Champlain, containing 987 inhabitants.

SHELBURN Bay, a bay on the N. coast of New Holland, between Oxfordness and Cape Grenville.

SHELBURNE, sometimes called *Port Roseway*, a seaport town of Nova Scotia, at the head of a bay, in the S.W. part of the province. At the conclusion of the American war, this place was made the seat of royalty, and it was designed to erect many buildings here, and in 1783 it contained above 600 families: but being neglected and unable to defend themselves, many of them afterwards left

the town; 90 miles W. of Halifax. N. lat.  $43^{\circ} 50'$ . W. long.  $63^{\circ} 15'$ .

SHELBURNE, a town of America, in the province of Massachusetts and county of Hampshire, containing 961 inhabitants; 98 miles W. of Boston.—Also, a town of New Hampshire, in the county of Cors, incorporated in 1769, and containing 176 inhabitants.

SHELBY. See SHEBBY.

SHELDAFLE, a name used in several parts of the kingdom for the chaffinch.

SHELDON, GILBERT, in *Biography*, archbishop of Canterbury, was born in 1598, at Stanton, in Staffordshire. His father was a menial servant of Gilbert, earl of Shrewsbury, though descended from an ancient family in Staffordshire. The subject of this article took his name from the earl, who was his god-father. Having laid the foundation of a good education, he was entered of Trinity college, Oxford, in 1613, and after taking the usual degrees was elected fellow of All Souls' college, in 1622. When he had taken orders he became chaplain to lord keeper Coventry, who made use of his services on various important occasions. As a reward for these services he presented him with a prebend of Gloucester, and recommended him to his majesty, as one extremely well versed in political affairs. When he had taken his doctor's degree, in 1634, he was elected warden of All Souls' college. He was also chaplain in ordinary to the king, and clerk of the college, and was in the road to farther preferment when the civil wars broke out, and checked his career. He was a zealous adherent to the royal cause, attended the king on various occasions, and rendered himself obnoxious to the parliament: on which account he was ejected from his wardenship, and imprisoned for six months. On his liberation, he retired to his friends in the country, and from his own purse, and the contributions of others, he sent frequent supplies to Charles II. during his exile. On the restoration he received ample rewards for his sufferings and steady loyalty, being restored to his offices, and promoted to the see of London.

The conference between the episcopal and presbyterian divines in 1661, was held at the Savoy, in bishop Sheldon's lodgings. On this occasion he is accused by the opposite party of want of fairness, and he rejected the proposal of an amicable discussion, and insisted that the Presbyterians should first bring in writing all their objections against the liturgy, and all the additions which they proposed. He did not appear often at the conference, and never entered into disputation, yet he was known to have had the principal share in the determination. To conciliate was not his object; he was resolved to carry his point by power: when it was debated in council in August 1662, whether the act of Uniformity should be punctually executed that month, or be suspended for a time, bishop Sheldon pleaded against the suspension, and carried the council with him. "If," says his biographer, "in these and other instances he appears too much the political churchman, in public spirit and munificence he sustained, after an exemplary manner, the character of a great prelate. He expended large sums upon the episcopal houses of the see of London, and being in 1665 translated to that of Canterbury, he rebuilt the library at Lambeth, and made many additions to its contents."

On the removal of lord Clarendon from the chancellorship of the university of Oxford, he was chosen to succeed him in December 1667, and he immortalized his name in that university by the erection, at his sole expence, of the celebrated theatre at Oxford. Of this act bishop Lowth says, "Munus dignum auctore—quod cum intueor et circumspicio videor mihi in ipsa Roma, vel in medijs Athenis, antiquis

tiquis illis, et cum maxime florentibus versari." This edifice was opened in July 1679, and almost immediately after the archbishop resigned the chancellorship, and retired from all public business: during the latter part of his life he chiefly resided at Croydon. He died at Lambeth, on the 9th of November, 1677, in the 80th year of his age.

This prelate appears to have been more attached to the duties of morality, than to the profession of any particular doctrines of religion: to young men of rank his advice was always this: "Let it be your principal aim to become honest men, and afterwards be as devout and religious as you will. No piety will be of advantage to yourselves or others, unless you are honest and moral men." Burnet says that "he seemed not to have a deep sense of religion, if any at all, and spoke of it commonly as an engine of government, and a matter of policy;" but he allows that he was a very generous and charitable man. From his own books it appears, that from the time of his becoming bishop of London till his death, he expended for public and charitable uses 66,000*l.* He published a sermon at the thanksgiving for the king's restoration. He was intimate with Chillingworth, and found means to overcome his scruples respecting subscription to the articles of the church of England.

SHELDON, formerly *Hungerford*, in *Geography*, a port-town of America, in the state of Vermont, and county of Franklin, containing 883 inhabitants; 14 miles E. of lake Champlain.

SHELE, a river of England, in the county of Northumberland, which runs into the Tyne, near its head.

SHELF, a term used by the miners in many parts of England, to express a distinction of the inner structure of the earth, so little known to philosophers, that they have no word to express it by. These workmen sometimes also express it by the term *fast ground*, or *fast country*. What they mean by this is, that part of the earth, which they find lying even, and in an orderly manner, and evidently having attained its primitive form and situation, unmoved by the waters of the general deluge, while the circumjacent, and upper strata, have plainly been removed, and tossed about.

It is evident to reason, that there must have been a very violent concussion of the superficial part of the earth, in the time of its being covered by the waters of the deluge; and experience as much evinces this as reason. Before this concussion it appears probable, that the uppermost surface of mineral veins, or loads, did in most places lie even with the then surface of the earth. The remains of this surface, found at different depths in digging, the miners express by the word *shelf*.

In this concussion of the waters covering the whole earth, its natural surface, together with the uppermost surface of those mineral veins, were then in many places loosened, and torn off; and the earth, and with it the mineral nodules, called *shoad-stones*, were carried down with the descending waters from hills into the adjacent vallies, and sometimes into the streams of rivers, by which they were washed to yet greater distances from their original place. On this depends the method of training mines. Phil. Trans. N<sup>o</sup> 69. See TRAINING.

SHELFY, or SLATY *Soil*, in *Agriculture*, that sort which is chiefly formed of a kind of thin laminated, brittle, slaty material, or which has it much mixed and incorporated with its other earthy parts. It is a prevailing sort of land in some districts; this sort of rotten slaty matter being largely intermixed with the light loamy mould that constitutes the earthy parts of it.

Where the subsoil or substratum is a schistus, or soft

slate, as is the case in some places in Cornwall, there is great difference, in point of fertility, in the land, according as the disposition of the laminæ is more flat, or the contrary; as when flat, the surface is more retentive of the manure which is employed; but when on the edge, what is called a greedy or hungry sort of land is formed, that permits the manure to be washed down through it in too ready a manner, and be lost. See SOIL.

SHELL, TESTA, in *Natural History*, a hard calcareous crust, serving to cover and inclose a kind of animal, hence called *testaceous*. See CONCHOLOGY and TESTACEOLOGY.

SHELLS, *Collecting and cleaning of*. See CONCHOLOGY.

SHELLS, *Figures and Colours, &c. of*. It is observed, that river-shells have not so agreeable or diversified a colour as the land and sea-shells; but the variety in the figure, colours, and other characters of sea-shells, is almost infinite. The number of distinct species we find in the cabinets of the curious is very great; and doubtless the deep bottoms of the sea, and the yet unsearched shores, contain multitudes more, yet unknown to us. Even the same species differ in some degree in almost every individual, so that it is rare to find any two shells which are alike in all respects. Bonan. Recreat. Ment. et Ocul. p. 49.

This wonderful variety, however, is not all the produce of one sea, or one country; the different parts of the world afford us their different beauties. Bonani observes, that the most beautiful shells we are acquainted with come from the East Indies, and from the Red sea. This is in some degree countenanced by what is found to this day; from the general observations of the curious, it seems that the sun, by the great heat that it gives to the countries near the line, exalts the colours of the shells produced there, and gives them a lustre and brilliancy, that those of colder climates always want; and it may be, that the waters of those vast seas, which are not subject to be weakened by fresh rivers, give a nourishment to the fish, that may add to the brilliancy of their shells.

The shores of Asia furnish us with the pearl oysters and scallops in great perfection. About Amboyna are found the most beautiful specimens of the cabbage-shell, the arrosir, the dual mantle, and the coral oysters, or echinated oysters. Here also are found a great variety of extremely beautiful muscles, tellinæ, and volutæ; some fine buccinums, and the shell called the *Ethiopian crown*, in its greatest perfection.

The dolia, the murices, and the cassandæ, are also found on these coasts in great beauty. Many elegant snails and serew-shells are also brought from thence; and finally the serapion and spider-shells. Hist. Nat. Eclairc. p. 168.

The Maldivæ, and Philippine islands, Bengal, and the coast of Malabar, abound with the most elegant of all the species of snails, and furnish many other kinds of shells in great abundance and perfection.

China abounds in the finest species of porcelain shells, and has also a great variety of beautiful snails.

Japan furnishes us with all the thicker and larger bivalves; and the isle of Cyprus is famous above all other parts of the world, for the beauty and variety of the patella, or limpet, found there.

America affords many very elegant shells, but neither in so great abundance nor beauty as the shores of Asia.

Panama is famous for the cylinders or rhombi, and we have beside, from the same place, some good porcelains, and a very fine species of dolium, or *concha globosa*, called from this place the *Panama purple shell*. One of the most beautiful of the cylinders is also known among our naturalists under the name of the *Panama shell*.

## SHELLS.

About Brazil, and in the gulf of Mexico, there are found murices and dolia of extreme beauty, and also a great variety of porcelains, purpuræ, pectens, neritæ, bucardiæ, or heart-shells, and elegant limpets.

The isle of Cayenne affords one of the most beautiful of the buccinum kind, and the Midas ear is found principally about this place.

Jamaica, and the island of Barbadoes, have their shores covered with porcelains, chamæ, and buccina; and at St. Domingo there are found almost all the same species of shells that we have from the East Indies, though they are less beautiful, and the colours more pale and dead. The pearl oyster is found also on this coast, but smaller than in the Persian gulf. At Martinico there are found in general the same shells as at St. Domingo, but yet less beautiful.

About Canada are found the violet chamæ, and the lakes of that country abound with muscles of very elegant pale blue and pale red colours; some species of these are remarkably light and thin; others are very thick and heavy.

The Great Bank of Newfoundland is very barren in shells: the principal kinds found there are muscles of several species, some of which are of considerable beauty.

About Carthage there are many mother-of-pearl shells, but they are not of so brilliant colours as those of the Persian gulf.

The island of Magellan, at the southern point of America, furnishes us with a very remarkable species of muscle, called by its name; and several very elegant species of limpets are found there, particularly the pyramidal.

In Africa, on the coast of Guinea, there is a prodigious quantity of that small species of porcelain, which is used there as money; and there is another species of porcelain on the same coast, which is all over white: the women make bracelets of these, and the people of the Levant adorn their hair with them.

The coast of Zanguebar is very rich in shells: we find there a vast variety of the large porcelains, many of them of great beauty; and the *nux maris*, or sea-nut, is very frequent there. Beside these, and many other shells, there are found on this coast all the species of nautili, many of which are very beautiful.

The Canary Isles are found to abound with a vast variety of the murices, and some other good shells; and we have from Madeira great variety of the echini, or sea-eggs, different from those of the European seas. Several species of muscles are also common there, and the auris marina is no where more abundant.

The Red sea is beyond all other parts of the world abundant in shells, so that scarcely any kind is wanting there; but those we principally have from thence are the purpuræ, porcelains, and echini marini.

The Mediterranean and Northern ocean contain a great variety of shells, and many of very remarkable elegance and beauty: they are upon the whole, however, greatly inferior to those of the East Indies. The Mediterranean abounds much more in shells than the ocean.

The gulf of Tarentum affords great variety of purpuræ, of porcelains, nautili, and elegant oysters; the coasts of Naples and Sardinia afford also the same, and with them a vast number of the solens of all the known species.

The island of Sicily is famous for a very elegant kind of oyster, which is white all over; pinnæ marinæ and porcelains are also found in great plenty there, with tellinæ and chamæ of many species, and a great variety of other beautiful shells.

Corfica is famous beyond all other places for vast quantities of the pinnæ marinæ, and many other very beautiful shells are found there. Lister, Hist. Conchyl.

About Syracuse are found the gondola shell, the alated murex, and a great variety of elegant snails, with some of the dolia and neritæ.

The Adriatic sea, or gulf of Venice, is less furnished with shells than almost any of the seas thereabout. Muscles and oysters of several species are, however, found there, and some of the cordiformes or heart-shells; there are also some tellinæ. About Ancona there are found vast numbers of the pholades buried in stone, and the aures marinæ are particularly frequent about Puzzoli. Bonani. Recreat. Ment. et Ocul.

The ports of Marseilles, Toulon, and Antibes, are full of pinnæ marinæ, muscles, tellinæ, and chamæ. The coasts of Bretagne afford great numbers of the conchæ anatifæ and ponslepieds; they are found on old rotten boards, on sea substances, and among clusters of sponges. The other ports of France, as Rochelle, Dunkirk, Brest, St. Maloes, and others, furnish oysters, excellent for the table, but of the common kind, and of no beauty in their shells; great numbers of muscles are also found there; and the common tellinæ, the onion-peel oysters, the solens, and conchæ anatifæ, are also frequent there. At Granville, in Lower Normandy, there are found very beautiful pectens, and some of the cordiformes, or heart-shells. Our own English coasts are not the least fruitful in shells, though they do not produce such elegantly painted ones as the Indies.

About Plymouth are found oysters, muscles, and solens, in great abundance; and there, and on most of our other shores, are numbers of the aures marinæ and dentalia, with pectens, which are very excellent food; and many elegant species of the chamæ and tellinæ are fished up in the sea about Scarborough, and other places.

Ireland affords us great numbers of muscles, and some very elegant scallop shells in great abundance, and the pholades are frequent on most of our shores. We have also great variety of the buccina and cochleæ, some volutæ; and on the Guernsey coast a peculiarly beautiful snail, called thence the *Guernsey-snail*.

The coasts of Spain and Portugal afford much the same species of shells with the East Indies, but they are of much fainter colours, and greatly inferior in beauty. Hist. Nat. Eclairc. p. 172.

There are, according to Tavernier and others, some rivers in Bavaria, in which there are found pearls of a fine water. About Cadiz there are found very large pinnæ marinæ, and some fine buccina. The isles of Majorca and Minorca afford a great variety of extremely elegant shells. The pinnæ marinæ are also very numerous there, and their silk is wrought into gloves, stockings, and other things. The Baltic affords a great many beautiful species, but particularly an orange-coloured pecten, or scallop shell, which is not found in any other part of the world.

The fresh-water shells are found much more frequently, and in much greater plenty, than the sea kinds; there is scarcely a pond, a ditch, or a river of fresh water, in any part of the world, in which there are not found vast numbers of these shells with the fish living in them. All these shells are small, and they are of very little beauty, being usually of a plain greyish or brownish colour. Our ditches afford us chamæ, buccina, neritæ, and some patellæ; but the Nile, and some other rivers, furnished the ancients with a species of tellina, which was large and eatable, and so much superior to the common sea tellina in flavour, that it is commonly known by the name of *tellina regia*, the royal tellina.

## SHELLS.

We have a small species of buccinum common in our fresh waters, which is very elegant, and always has its operculum in the manner of the larger buccina; a small kind of muscle is also very common, which is so extremely thin and tender, that it can hardly be handled without breaking to pieces.

The large fresh-water muscle, commonly called in England the *horse muscle*, is too well known to need a description, and the size of this gives it a difference from all other fresh-water shells.

**SHELLS, Polishing of.** (See CONCHOLOGY.) This is an art of no long standing in the world, in its present perfection; and as the love of sea-shells is become so common among us, it may not be disagreeable to the reader to find some instructions in executing so pleasing a method of adding to their natural beauty, the rules for which are at present so little known, though the effect of them be so much esteemed.

Among the immense variety of shells which we are acquainted with, some are taken out of the sea, or found on its shores in all their perfection and beauty; their colours being all spread by nature upon the surface, and their natural polish superior to any thing that art could give. Where nature is in herself thus perfect, it were madness to attempt to add any thing to her charms; but in others, where the beauties are latent and covered with a coarser outer skin, art is to be called in, and the outer veil being taken off, all the internal beauties appear.

Among the shells which are found naturally polished are the porcelains, or cowries, the cassanders, the dolia, or conchæ globosæ or tuns, some buccina, the volutes, and the cylinders, or olives, or, as they are generally though improperly called, the rhombi; excepting only two or three, as the tiara, the plume, and the butter-tub rhombus; where there is an unpromising film on the surface, hiding a very great share of beauty within. Though the generality of the shells of these genera are taken out of the sea in all their beauty, and in their utmost natural polish, there are several other genera, in which all, or most of the species, are taken up naturally rough and foul, and covered with an epidermis, or coarse outer skin, which is in many rough and downy, or hairy. The tellinæ, the muscles, the cochleæ, and many others, are of this kind. The more nice collectors, as naturalists, insist upon having all their shells in their native and genuine appearance, as they are found when living at sea; but the ladies who make collections hate the disagreeable outides, and will have all such polished. It would be very adviseable, however, for both kinds of collectors to have the same shells in different specimens, both rough and polished; the naturalist would, by this means, besides knowing the outside of the shell, be better acquainted with its internal characters than he otherwise could be, and the lady would have a pleasure in comparing the beauties of the shell, in its wrought state, to its coarse appearance as nature gives it. How many elegancies in this part of the creation must be wholly lost to us, if it were not for the assistance of an art of this kind! Many shells in their native state are like rough diamonds, and we can form no just idea of their beauties till they have been polished and wrought into form.

Though the art of polishing shells is a very valuable one, yet it is very dangerous to the shells; for without the utmost care, the means used to polish and beautify a shell often wholly destroy it. When a shell is to be polished, the first thing to be examined is whether it have naturally a smooth surface, or be covered with tubercles or prominences.

A shell which has a smooth surface, and a natural dull

polish, need only be rubbed with the hand, or with a piece of chamoy leather, with some tripoli, or fine rotten stone, and will become of a perfectly bright and fine polish. Emery is not to be used on this occasion, because it wears away too much of the shell. This operation requires the hand of an experienced person, that knows how superficial the work must be, and where he is to stop; for in many of these shells the lines are only on the surface, and the wearing away ever so little of the shell defaces them. A shell that is rough, foul, and crusty, or covered with a tartareous coat, must be left a whole day sleeping in hot water; when it has imbibed a large quantity of this, it is to be rubbed with rough emery on a tick, or with the blade of a knife, in order to get off the coat. After this it may be dipped in diluted aqua fortis, spirit of salt, or any other acid; and after remaining a few moments in it, be again plunged into common water. This will greatly add to the speed of the work. After this it is to be well rubbed with linen cloths impregnated with common soap; and when by these several means it is made perfectly clean, the polishing is to be finished with fine emery and a hair-brush. If after this the shell when dry appears not to have so good a polish as was desired, it must be rubbed over with a solution of gum arabic; and this will add greatly to its gloss, without doing it any sort of injury. The gum water must not be too thick, and then it gives no sensible coat, only heightening the colours. The white of an egg answers this purpose also very well; but it is subject to turn yellow. If the shell has an epidermis, which will by no means admit the polishing of it, it is to be dipped several times in diluted aqua fortis, that this may be eaten off; and then the shell is to be polished in the usual way with putty, fine emery, or tripoli, on the hair of a fine brush. When it is only a pellicle that hides the colours, the shells must be steeped in hot water, and after that the skin worked off by degrees with an old file. This is the case with several of the cylinders, which have not the natural polish of the rest.

When a shell is covered with a thick and fatty epidermis, as is the case with several of the muscles and tellinæ; in this case aqua fortis will do no service, as it will not touch the skin; and a rough brush and coarse emery are to be used; and if this does not succeed, seal-skin, or, as the workmen call it, *fish-skin* and *pumice-stone*, are to be employed.

When a shell has a thick crust, which will not give way to any of these means, the only way left is to plunge it several times into strong aqua fortis, till the stubborn crust is wholly eroded. The limpets, *auris marina*, the helmet-shells, and several other species of this kind, must have this sort of management; but as the design is to shew the hidden beauties under the crust, and not to destroy the natural beauty and polish of the inside of the shell, the method of using the aqua fortis must be this; a long piece of wax must be provided, and one end of it made perfectly to cover the whole mouth of the shell; the other end will then serve as a handle, and the mouth being stopped by the wax, the liquor cannot get in to the inside to spoil it; then there must be placed on a table a vessel full of aqua fortis, and another full of common water.

The shell is to be plunged into the aqua fortis; and after remaining a few minutes in it, is to be taken out, and plunged into the common water. The progress the aqua fortis makes in eroding the surface is thus to be carefully observed every time it is taken out; the point of the shell, and any other tender parts, are to be covered with wax, to prevent the aqua fortis from eating them away; and if there be any worm-holes, they also must be stopped up with wax, otherwise

wife the aqua fortis would soon eat through in those places. When the repeated dippings into the aqua fortis shew that the coat is sufficiently eaten away, then the shell is to be wrought carefully with fine emery and a brush; and when it is polished as high as can be by this means, it must be wiped clean, and rubbed over with gum-water, or the white of an egg. In this sort of work the operator must always have the caution to wear gloves, otherwise the least touch of the aqua fortis will burn the fingers, and turn them yellow; and often, if it be not regarded, will eat off the skin and the nails.

These are the methods to be used with shells, which require but a moderate quantity of the surface to be taken off; but there are others which require to have a larger quantity taken off, and to be uncovered deeper; this is called entirely scaling a shell. This is done by means of an horizontal wheel of lead or tin, impregnated with rough emery; and the shell is wrought down in the same manner in which stones are wrought by the lapidary. Nothing is more difficult, however, than the performing this work with nicety; very often shells are cut down too far by it, and wholly spoiled; and to avoid this, a coarse vein must be often left standing in some place, and taken down afterwards with the file, when the cutting it down at the wheel would have spoiled the adjacent parts.

After the shell is thus cut down to a proper degree, it is to be polished with fine emery, tripoli, or rotten stone, with a wooden wheel turned by the same machine as the leaden one, or by the common method of working with the hand with the same ingredients, when a shell is full of tubercles, or protuberances, which must be preserved. It is then impossible to use the wheel; and if the common way of dipping into aqua fortis be attempted, the tubercles, being harder than the rest of the shell, will be eat through before the rest is sufficiently scaled, and the shell will be spoiled; in this case industry and patience are the only means of effecting a polish. A camel's-hair pencil must be dipped in aqua fortis, and with this the intermediate parts of the shell must be wetted, leaving the protuberances dry; this is to be often repeated, and after a few moments the shell is always to be plunged into water to stop the erosion of the acid, which would otherwise eat too deep, and destroy the beauty of the shell. When this has sufficiently taken off the foulness of the shell, it is to be polished with emery of the finest kind, or with tripoli, by means of a small stick, or the common polishing stone of the goldsmiths may be used.

This is a very tedious and troublesome thing, especially when the echinated oysters and murices, and some other such shells, are to be wrought; and what is worst of all is, that when all this labour has been employed, the business is not well done; for there still remain several places which could not be reached by any instrument; so that the shell must necessarily be rubbed over with gum-water, or the white of an egg afterwards, in order to bring out the colours, and give a gloss: in some cases it is even necessary to give a coat of varnish.

These are the means used by artists to brighten the colours, and add to the beauty of shells; and the changes produced by polishing in this manner are so great, that the shell is often not to be known afterwards for the same it was; and hence we hear of new shells in the cabinets of collectors, which have no real existence as separate species, but are the polished appearance of others well known. To caution the reader against errors of this kind, it may be proper to add the most remarkable species thus usually altered.

The onyx-shell, or volute, called by us the purple or

violet-tip, which in its natural state is of a simple pale brown, when it is wrought slightly, or polished with just the superficies taken off, is of a fine bright yellow; and when it is eat away deeper, it appears of a fine milk-white, with the lower part bluish: it is in this state that it is called the onyx-shell; and it is preserved in many cabinets in its rough state, and in its yellow appearance as different species of shells.

The violet-shell, so common among the curious, is a species of porcelain, or common cowry, which does not appear in that elegance till it has been polished; and the common *auris marina* shews itself in two or three different forms, as it is more or less deeply wrought. In its rough state it is dusky and coarse, of a pale brown on the outside, and pearly within: when it is eaten down a little way below the surface, it shews variegations of black and green; and when still farther eroded, it appears of a fine pearly hue within and without.

The nautilus, when it is polished down, appears all over of a fine pearly colour; but when it is eaten away but to a small depth, it appears of a fine yellowish colour, with dusky hairs. The burgau, when entirely cleared of its coat, is of the most beautiful pearl-colour; but when only slightly eroded, it appears of a variegated mixture of green and red: whence it has been called the parrot-shell. The common helmet-shell, when wrought, is of the colour of the finest agate; and the muscles, in general, though very plain shells, in their common appearance, become very beautiful when polished, and shew large veins of the most elegant colours. The Persian shell, in its natural state, is all over white, and covered with tubercles; but when it has been ground down on a wheel, and polished, it appears of a grey colour, with spots and veins of a very bright and highly polished white. The limpets, in general, become very different when polished, most of them shewing very elegant colours; among these the tortoise-shell limpet is the principal; it does not appear at all of that colour or transparency, till it has been wrought.

That elegant species of shell called the junquil-chama, which has deceived so many judges of these things into an opinion of its being a new species, is only a white chama, with a reticulated surface; but when this is polished, it loses at once its reticular work and its colour, and becomes perfectly smooth, and of a fine bright yellow; and the violet-coloured chama of New England, when worked down and polished, is of a fine milk-white, with a great number of blue veins, disposed like the variegations in agates.

The asses ear-shell, when polished, after working it down with the file, becomes extremely glossy, and obtains a fine rose-colour all about the mouth. There are some of the most frequent among an endless variety of changes wrought on shells by polishing; and we find there are many of the very greatest beauties of this part of the creation which must have been lost, but for this method of searching deep in the substance of the shell for them.

The Dutch are very fond of shells, and are very nice in their manner of working them: they are under no restraint, however, in their works, but use the most violent methods, so as often to destroy all the beauty of the shell. They file them down on all sides, and often take them to the wheel, when it must destroy the very characters of the species. Nor do they stop at this, but, determined to have beauty at any rate, they are for improving upon nature, and frequently add some lines and colours with a pencil, afterwards covering them with a fine coat of varnish; so that they seem the natural lineations of the shell. The Dutch cabinets are by

## SHELLS.

this means made very beautiful, but they are by no means to be regarded as instructors in natural history. There are some artificers of this nation who have a way of covering shells all over with a different tinge from that which nature gives them; and the curious are often deceived by these tricks into the purchasing of them as new species.

There is another kind of work bestowed on certain species of shells, particularly the nautilus; this is the engraving on it lines and circles, and figures of stars, and other things: this is too obvious a work of art to suffer any one to suppose it natural. Bonani has figured several of these wrought shells at the end of his work; but it is miserably throwing away labour to do them: the shells are spoiled as objects of natural history by it, and the engraving is seldom worth any thing. They are principally done in the East Indies.

Shells are subject to several imperfections: some of these are natural, and others accidental; the natural ones are the effect of age, or sickness in the fish. The greatest mischief happens to shells by the fish dying in them. The curious in these things pretend to be always able to distinguish a shell taken up with the fish alive, from one found on the shores: they call the first a living, the second a dead shell, and say that the colours are always much the faintest in the dead shells. When the shells have lain long dead on the shores, they are subject to many injuries, of which the being eaten by sea-worms is not the least: age renders the finest shells livid or dead in their colours.

The finest shells are those which are fished up at sea, not found on the shores. The other natural defects of shells are their having morbid cavities, or protuberances, in parts where there should be none. When the shell is valuable, these faults may be hid, and much added to the beauty of the specimen, without at all injuring it as an object of natural history, which should always be the great end of collecting these things. The cavities may be filled up with mastic, dissolved in spirit of wine, or with isinglass: these substances must be either coloured to the tinge of the shell, or else a pencil dipped in water-colours must finish them up to the resemblance of the rest, and then the whole shell being rubbed over with gum-water, or with the white of an egg, scarcely any eye can perceive the artifice: the same substances may also be used to repair the battered edge of a shell, provided the pieces chipped off be not too large. And when the excrescences of a shell are faulty, they are to be taken down with a fine file. If the lip of a shell be so battered, that it will not admit of repairing by any cement, the whole must be filed down to an evenness, or ground on the wheel.

**SHELLS, Fossil.** See CONCHOLOGY and PETRIFICATIONS.

Shells are frequently found under ground, in places far remote from the sea, in mines, and even on the tops of mountains; but how they should come thither is a thing that naturalists are greatly divided about. The most usual and easy opinion is, that those parts have been formerly sea, or, at least, have been overflowed thereby; and many even go back as far as the grand deluge for this. Others take these to be the natural places of their birth or formation, some of them being found little other than crude clay, others of the same texture with the rock to which they grow, though others seem of as absolute a shelly substance as any in the sea. In effect, they say, these may be only so many different gradations of nature, which can as well produce shells in mines as in the sea, there being no want of saline or earthy particles for the purpose; nor is there any great difference between some sorts of spars and sea-shells.

Dr. Lister judges, that the shells found in stone quarries

were never any part of an animal, and gives this reason for it, that quarries of different stone yield quite different species of shells; different not only from one another, but from any thing in nature besides, which either sea or land does yield. This opinion has been since proved erroneous, and all these bodies to have been really once parts of living animals. See FOSSILS, *Adventitious*, MARINE Remains, and *Formed STONES*.

Of these shells, some are found remaining almost entirely in their native state, but others are variously altered, by being impregnated with particles of stone, and of other fossils; in the place of others there is found mere stone or spar, or other native mineral body, expressing all their lineaments in the greatest nicety, as having been formed wholly from them, the shell having been first deposited in some solid matrix, and thence dissolved by very slow degrees, and this matter left in its place, on the cavities of stone and other solid substances, out of which shells had been dissolved and washed away, being afterwards filled up less slowly with these different substances, whether spar or whatever else: these substances, so filling the cavities, can necessarily be of no other form than that of the shell, to the absence of which the cavity was owing, though all the nicer lineaments may not be so exactly expressed. Beside these, we have also in many places masses of stone formed within various shells; and these having been received into the cavities of the shells, while they were perfectly fluid, and having therefore nicely filled all their cavities, must retain the perfect figures of the internal part of the shell, when the shell itself should be worn away, or perished from their outside. The various species we find of these are in many genera as numerous as the known recent ones; and as we have in our own island not only the shells of our own shores, but those of many other very distant ones, so we have also many species, and those in great numbers, which are in their recent state, the inhabitants of other yet unknown or unsearched seas and shores.

The cockles, muscles, oysters, and the other common bivalves of our own seas, are very abundant; but we have also an amazing number of the nautilus kind, particularly of the nautilus græcorum, which though a shell not found living in our own, or any neighbouring seas, yet is found buried in all our clay-pits about London and elsewhere; and the most frequent of all fossil shells in some of our counties, are the conchæ anomix, which yet we know not of in any part of the world in their recent state. Of this sort also are the cornua ammonis and the gryphitæ, with several of the echinitæ and others.

The exact similitude of the known shells, recent and fossil, in their several kinds, will by no means suffer us to believe, that these, though not yet known to us in their living state, are, as some have idly thought, a sort of lusus naturæ.

It is certain, that of the many known shores, very few, not even those of our own island, have been yet carefully searched for the shell-fish that inhabit them; and as we see in the nautilus græcorum an instance of shells being brought from very distant parts of the world to be buried there, we cannot wonder, that yet unknown shores, or the unknown bottoms of deep seas, should have furnished us with many unknown shell-fish, which may have been brought with the rest; whether that were at the time of the general deluge, or the effect of any other catastrophe of a like kind, or by whatever other means to be left in the yet unhardened matter of our stony and clayey strata. Hill's Hist. of Foss. p. 616.

Fossil shells are found to be of great use in manuring land. See MANURING.

## SHELLS.

They are much used in France for this purpose; and Mr. Reaumur treats of their effects in fertilizing the earth very fully, concluding his useful account of these substances by observing, that it is much more easy to account for the manner of their acting upon land, than for the manner of their coming where they are found. It has been the favourite system of our Dr. Woodward, that all these shells were the remains of the universal deluge, which having overflowed the whole earth, might easily leave them in all places; but Mr. Reaumur has much more rationally accounted for their coming to those parts of France, where they are found at this time in such vast abundance, by carefully tracing the course of the beds of them, so far as known there, and easily proving that all that extent of country, under which they are found, may have been once overflowed by the sea without a deluge; it being the very track that a large body of waters, let in at one part of the kingdom, must have taken, in order to getting out at another. Mem. de l'Acad. Par. 1720.

**SHELL, Arabian**, a name given by some to a species of porcelain shell, not because it is found on the coast of Arabia, but because its lines and variegations are supposed to represent the figures of Arabic characters.

**SHELL, Aurora**, a very remarkable species of shell-fish, found in cabinets of the curious. It is of the figure of a bird, having a head, wings, and tail, and is of a flame-colour; it owes much of its beauty, however, to art and accident; the shell is an oyster of a peculiar variation of figure from the common one; the head of the bird is the cardo or hinge; the wings are the body of the shells; and the tail is a peculiar process, like that of the marteau, only single.

It is naturally of a dusky brown on the outside, and pearly within, but when its rough coat is taken off, it appears of this beautiful flame-colour.

**SHELL, Caterpillar**. See TURBO.

**SHELL, Centre**, a name given to the balanus marinus, a kind of sea-shell of the multivalve kind, with an open mouth, frequently found fixed to the bottoms of ships, and other things covered with sea-water. See BALANUS and CONCHOLOGY.

**SHELL, Chalice**, or *Cup-shell*, a species of the balanus. See BALANUS.

**SHELL, China-letter**, a name given by many to that species of chama, usually called by authors the *chama Arabica*. It is of a pale brownish ground, and is variegated with a great number of black lines, which are as slender as the strokes of a pen, and are of such odd figures, that they represent some of the Arabic, or, as others fancy, Chinese characters. See CHAMA.

**SHELL, Crown Imperial**, a species of the voluta.

**SHELL, Dog-tooth**, a species of dentalis.

**SHELL, Ear**. See AURIS.

**SHELL, Guinea**, the English name for a very beautiful variegated species of voluta, called by the French *la speculation*.

**SHELL, Heart**. See CARDIUM, under CONCHOLOGY.

**SHELL, Helmet**, the name of a kind of murex, of which there are several species. They all approach somewhat towards a triangular figure, and are free from any long spines.

**SHELL, Leopard**, the English name of the pardus, a kind of voluta, so called from its spots resembling those of a leopard. There are three kinds of this, one spotted with black, another with yellow, and another with red.

**SHELL, Leveret**, a name given by many to a species of porcelain-shell, resembling a young hare in colour.

**SHELL, Lightning**, a name given by some authors to a species of murex, with variegations on its body, resembling the pictures we commonly see of flashes of lightning.

**SHELL, Map**, the name given by some to a peculiar species of porcelain-shell, the figures on which represent the lines on a map.

**SHELL, Needle**. See CENTRONIA and NEEDLE.

**SHELL, Noah's Ark**. See NOAH.

**SHELL, Oyster**. See OYSTER.

**SHELL, Old Wife**, the name given by some to that species of chama, which the French also have called *vieille ridée*.

**SHELL, Onion**, a species of oyster.

**SHELL, Pipe**. See ENTALIUM.

**SHELL, Saddle**, the name of a species of oyster, which in some degree represents a saddle in its shape.

**SHELL, St. James's**, a name given by writers on shells to a very beautiful species of variegated pecten.

**SHELL, St. Michael's**, a name given by authors to a species of pecten, or scallop-shell. It is of a bright yellow colour.

**SHELL, Scorpion**, the name of a species of murex, very much approaching to the nature of the spider-shell. This is a common shell in cabinets; it is of a yellow colour, and very deeply ridged, and full of tubercles; there arise from the lip of the shell five large spines, or, as they are usually called, fingers, and two others, which are very much bent, the one from the head, the other from the tail: these are very elegantly radiated with white, and a fine violet colour on the lips.

**SHELL, Screw**. See TURBO.

**SHELL, Small-pox**, a name given to a remarkable kind of concha venerea, or porcelain-shell, the protuberances on the surface of which are supposed to represent the pustules of the small-pox. There are two species of this shell, the one white, with flattish protuberances, the other greenish, with more elevated ones.

**SHELL, Snake**, the name given by many to that beautiful species of porcelain-shell, the spots of which represent those of a snake's skin.

**SHELL, Spider**. See ARANEA.

**SHELL, Strawberry**, a name given by collectors of shells to a very beautiful species of cordiformis, spotted with small round red spots.

**SHELL, Swallow**, a name given by authors to a species of oyster, which in some degree represents the figure of a small bird flying.

**SHELL, Tiger**, the name of a species of porcelain, or concha venerea, supposed to represent the spots on a tiger's skin.

**SHELL, Toe**. See POLLICIPES.

**SHELL, Tortoise**. See TORTOISE.

**SHELL, Trumpet**. See TRUMPET.

**SHELL, Turban**. See TURBAN.

**SHELL, Turnip**. This is a species of sea-shell, by others called the *radish shell*; it is exactly of the shape of a turnip, and is of the dolium, or concha globosa kind. Those who have called it the radish shell, allude to the great black round-rooted radish, not to our common radish.

**SHELL, Turtle**, the name of two species of shells. See MUREX and VOLUTA.

**SHELL, in Agriculture**, a term applied to a hard, and as it were stony covering, with which certain substances and animals are defended, and thence in the latter case called shell-fish. It is observed that the vast beds of fossil shells found at great depths in the earth, as well as those found lying

## SHELLS.

lying on the sea-shore, make an excellent manure for cold clayey lands. See SAND and CLAY.

It is likewise a term applied to the light calcined pieces of calcareous stones, which have been converted into lime; and also to the rind of turnips scooped by sheep, which are mostly applied to the purpose of feeding the store-sheep. See LIME and TURNIPS.

*SHELL-Apple*, in *Ornithology*, an English name for the loxia or crowsbill, given from his manner of splitting an apple, and feeding on the kernels, leaving the shell of the pulp untouched.

*SHELL-Drake*, a common English name for the tadorna.

*SHELL-Fish*, a collective name for fishes naturally inclosed in shells. These animals are in general oviparous, very few instances having been found of such as are viviparous. Among the oviparous kinds, anatomists have found that some species are of different sexes in the different individuals of the same species, but others are hermaphrodites, every one being in itself both male and female: in both cases their increase is very numerous, and scarcely inferior to that of plants, or of the most fruitful of the insect class. The eggs are very small, and are hung together in a sort of clusters by means of a glutinous humour, which is always placed about them, and is of the nature of the jelly of frogs' spawn; by means of this they are not only kept together in the parcel, but the whole cluster is fastened to the rocks, shells, or other solid substances, and thus they are preserved from being driven on shore by the waves, and left where they cannot succeed.

*SHELL-Gall-Insect*, an insect of the gall-insect class, somewhat resembling those which are called the boat-fashioned ones, but differing in this, that as the two ends of that species are not very different in form, in this kind one of the ends is sharp and pointed in comparison with the other.

It has its name of shell-insect from the resemblance it bears to a muscle-shell; as it is, in its whole form, not unlike one of the two shells in which the common sea-muscle is inclosed, but the pointed end of this insect is much more extended in length than the smaller end of this shell.

This species is extremely small, and may be easily mistaken for the minute case out of which some small insect has escaped; or in another state, for the nest in which some small insect had deposited its eggs; but if the assistance of the microscope be called in, they will easily be discovered to be true gall-insects, even as soon as they are hatched from the eggs. This species, at its full growth, is so small, that it requires good eyes to discover it: it is brown, very smooth, and polished on the surface, and much of the colour of the bark of some trees; it has usually an edge of a cottony matter, visible where its sides touch the tree, and its eggs are always deposited on a fine cottony bed; the young ones are white, flat, and have two small horns, and six legs; in this state they are known to be of the gall-insect class, not by their likeness to their parent, but to the young gall-insects of other species. They march about very briskly for some time after they are hatched, and after that fix themselves, and then begin to grow, and by degrees alter their form, till they at length are of the same shape with their parent. Reaumur, Hist. Inf. tom. iv. p. 69, 70.

*SHELL-Marle*, in *Agriculture*, a substance of the marly kind, which is of a flaky or shelly nature. Though Mr. Marshall has not seen this material made use of in any of the southern parts of this country, he supposes it highly probable, that in the more northern counties it may be found in considerable quantity; and that in different parts of Scotland, it is in common use as a manure. And he considers it as usually

found in low moist situations, under what is termed bog-meadow, a sort of half-reclaimed morass; namely, tough, coarse sward, formed upon a depth of black moory earth, which rests on the marle: this being, in some instances, several feet in depth. In respect to appearance, the colour is nearly white. Its consistence, in the pit, is that of soft curd, roughly broken; with the perceptible remains of small shells interspersed among it; and generally with some portion of earthy particles. It was found by analysis, that one hundred grains of a specimen taken in 1793, from the extraordinary pits on the estate of Auchtertyre, belonging to the late sir William Murray, on the southern skirts of the highlands of Perthshire, yielded eighty-two grains of calcareous earth: the residue being brown earthy matter, mostly, it is probable, animal mould, with a slight intermixture of vegetable fibres. One hundred grains, taken from a pit in Strath Tay, within the central highlands, yielded seventy-four grains of chalk; the residue being similar to the above. The search for this species of marle is so obvious and easy, that nothing but unpardonable neglect can suffer a quantity of it to remain within an estate (situated in a country where it is known to abound) unknown to its manager. Wherever, in vallies and dips of surface, level water-formed lands (whether they are already swarded over, or yet remain in a state of morass) are found, there insert the borer: not in one place only, but in various parts of it, that no hollow receptacle of marle may be missed by the farmer.

And with marles of the fossil kind it is remarked, that where, by analysis, the proportion of chalk is found to be small, as not more than one-third of the whole; if the earthy matter with which it is combined appears to be of a rich fertilizing nature, such marle becomes, he thinks, a proper subject of trial in the field. And a good method for making this sort of trial, is to spread the marle, at a leisure time, as in winter, or the early part of summer, upon grass-land; and catching a favourable opportunity, when the soil is in a mellow friable state, between wet and dry, to break down and spread the lumps, with the roller and harrow, to give freedom to the grass, and an opportunity of gathering off the stones and rubbish, which may have been carried on with the marle; and in order that summer showers may wash the finer parts of it down into the soil, while it is open to receive them; repeating the operation as often as it may be required. And he knows no better method than this, by which to apply marles, on a large scale, in practice.

*SHELL-Sand*, a name given by the farmers, in some parts of England, to the fragments of shells found on the sea-shores, and ground to a sort of powder, so that they resemble sand. See MANURING.

There is also another kind, used as this is, in some parts of Cornwall, and composed of fragments of a sort of tender white coral. This is found principally about Falmouth, and is called by the same name of shell-sand, though very improperly. All the kinds are of great use in agriculture, but they are differently esteemed by the farmers, as they are more or less rich, which they know by their colours: the reddish kind is esteemed most of all; next to this the blue is judged the best, and after this the white. Such as is dredged up from under the water, is always found better than such as is found dry on the shores; and such as is entirely composed of shells is to be chosen, rather than such as has fragments of stone among it, which is a very common case. See SAND, and Shelly SAND.

*SHELL-Toothed*, in the *Manege*, an appellation given to a horse that from four years old to old age, naturally, and without

without any artifice, bears mark in all his fore-teeth, and there still keeps that hollow place with the black mark, which is called in French *germe de seve*, i. e. *the eye of a bean*, inasmuch, that at twelve or fifteen he appears with the mark of a horse that is not yet six; for in the nippers of other horses, the hollow place is filled, and the mark disappears towards the sixth year, by reason of the wearing of the tooth. About the same age it is half worn out in the middling teeth, and towards the eighth year it disappears in the corner teeth: but after a shell-toothed horse has marked, he marks still equally in the nippers, the middling, and the corner teeth; which proceeds from this, that having harder teeth than other horses, his teeth do not wear, and so he does not lose the black spot.

Among the Polish, Hungarian, and Croatian horses, we find a great many of them hollow-toothed, and generally the mares are more apt to be so than the horses.

**SHELL**, in *Artillery*. See BOMB and MORTAR.

**SHELLS**, *Message*, are howitz-shells, within which are inclosed a letter, or other papers; the fuze-hole is stopped up with wood or cork, and the shells are fired into a garrison or camp.

**SHELL of a Block**, in *Mechanics*, is the outer frame or case, in which the sheave or wheel is contained, and traverses about its axis.

**SHELL-Room**, in *Ship-Building*, a compartment in a bomb-veffel, fitted up with strong shelves, excavated so as to receive the bomb-shells when charged; it is therefore built as secure as possible, to prevent accident from fire.

**SHELLS**, *Littoral*. See LITTORAL.

**SHELL-Gold**. See GOLD.

**SHELL-Silver**. See SILVER.

**SHELL Island**, in *Geography*, a small island near the coast of Carolina, in Pamlico sound. N. lat.  $34^{\circ} 50'$ . W. long.  $76^{\circ} 30'$ .

**SHELL Key**, a small island, or rather rock, in the gulf of Mexico. N. lat.  $29^{\circ} 48'$ . W. long.  $89^{\circ} 15'$ .

**SHELLA**, a walled town of Morocco, on the eastern side of Rabat, in N. lat.  $34^{\circ} 3'$ . This is sacred ground, and contains many Moorish tombs, that are held in great veneration; and the town is a sacred asylum, entered only by Mahometans. Shella was probably the Carthaginian metropolis on the coast of the ocean. Various Roman and ancient African coins were frequently dug up here, but their high price induced the Jews to imitate them, and thus to deceive amateurs, and hence has arisen a suspicion even of the antiques themselves. The place is now in a state of decay; 4 miles E. of Salee.

**SHELLACK POINT**, a cape of the Isle of Man, forming the N. part of Ramsey bay.

**SHELLDRAKE RIVER**, a river of Canada, which runs into the river St. Lawrence, N. lat.  $50^{\circ} 20'$ . W. long.  $64^{\circ} 50'$ .

**SHELLENBERG**, a mountain of Bavaria, occupied by the Swedes, and strongly fortified in the 30 years' war; 3 miles N.E. of Donawert.

**SHELLIFF**, the *Ghinala* of antiquity, a river of Africa, and the most considerable in the kingdom of Algiers, which rises in the northern side of the Atlas, and runs into the Mediterranean, N. lat.  $36^{\circ} 10'$ . E. long.  $0^{\circ} 24'$ .

**SHELLNESS**, a cape at the E. end of the island of Shepey. N. lat.  $51^{\circ} 22'$ . E. long.  $0^{\circ} 50'$ .

**SHELLUHS**, a class of the inhabitants in the dominions of the emperor of Morocco: they occupy the Atlas mountains, and the various branches of them S. of Morocco; living generally in towns, and, for the most part, occupied in husbandry like the Berberbers, though differing from them in

their language, dress, and manners. They subsist almost wholly on Affoua (barley meal made into gruel), and barley roasted or granulated, which they mix with cold water when travelling, and they call it "Zimata." They occasionally indulge in the use of "Cuscufoe," a nutritive farinaceous food, made of granulated flour, and afterwards boiled by steam, and mixed with butter, mutton, fowls, and vegetables. Many families among them are said to be descended from the Portuguese, who formerly possessed all the ports on the coast, but who, after the discovery of America, gradually withdrew thither. East of Morocco, near Dimenet, on the Atlas mountains, there is still remaining a church, having inscriptions in Latin over the entrance, supposed to have been built by them, which, being superstitiously reported to be haunted, has escaped destruction. Their language is called Amazirk.

**SHELOPGUR**, a town of Hindoostan, in the Carnatic; 18 miles N.W. of Tricolor.

**SHELTER**, in *Agriculture*, a term applied to the means of affording warmth, and procuring protection for lands and live-stock in situations which are too much exposed to storms, and inclement seasons. This is mostly accomplished by the use of trees, which should be chosen of the most proper shapes and kinds for effecting the purpose, as those which are the most branchy from the ground, and the most permanent and close in their foliage. The fir tribe, the holly, and the beech, are probably the most suited to this intention, though there are great numbers that may be made use of in this way.

Proper shelter has the effect of producing much improvement in land, trees, plants, and live-stock. See SHELTERING *Plantations*.

**SHELTER Island**, in *Geography*, a small island at the E. end of Long island, in Suffolk county, New York, about five miles from E. to W., and seven from N. to S. It is fertile, and contains about 8000 acres; it was incorporated in 1788, and is said to contain 201 inhabitants. It furnishes cattle, sheep, and poultry.

**SHELTERING PLANTATIONS**, in *Agriculture*, the means of guarding and protecting them, so as to promote the growth and advancement of the young trees. This is frequently necessary, and of very great utility. In some very exposed situations, trees cannot indeed be raised to any advantage without it. The business is performed in different manners, according to their nature and circumstances. See PLANTATION.

**SHELTERS**, *HORIZONTAL*. See HORIZONTAL.

**SHELTIE**, the name of a small, but strong kind of horse, found in the island of Zeland, commonly called *Sherland*. In the country, the price of one of these horses was formerly about a guinea.

**SHELVES**, in *Sea Language*, a general name given to any dangerous shallows, sand banks, or rocks; lying immediately under the surface of the water, so as to intercept any ship in her passage, and endanger her destruction.

**SHELVING-ROADS**, in *Rural Economy*, are such as are formed in a somewhat shelving manner, either on both sides from the middle part, or in the whole from side to side. It is a mode that forms a great improvement in making roads in different situations; as a greater travelling breadth is gained without ruts being formed. And it is particularly applicable in making the side long roads on the declivity of hill, &c. See ROAD.

**SHELVINGS**, in *Agriculture*, a name applied to the moveable side-rails of a waggon or cart, which are occasionally put on for top loads.

SIEMEN,

**SHEMEN**, in *Geography*, a town of Curdistan; 44 miles N.W. of Kerkuk.

**SHEMIUM**, a town of Persia, in the province of Khorassan; 10 miles N.W. of Herat.

**SHENANDOAH**, a county of Virginia, bounded N. by Frederick, and S. by Rockingham. It contains 13,646 inhabitants, of whom 1038 are slaves. Its chief town is Woodstock.

**SHENANDOAH**, or *Shenando*, a river of Virginia, which rises in Augusta county, and after running a N.E. course of about 200 miles, joins the Patowmack in about N. lat. 38° 4', just before the latter bursts through Blue Ridge. This river is composed of four branches, S. river, Middle river, N. river, and Shenandoah, which, though the smallest branch, gives name to the united streams. It is navigable about 100 miles, and might be rendered so through its whole course, at a small expence. When this is done, it will convey the produce of the richest part of the state to Washington.

**SHENANDOAH Valley**, a valley which extends from Winchester in Virginia, to Carlisle and the Susquehanna in Pennsylvania, chiefly inhabited by Germans and Dutch.

**SHENANGO**, a town of Pennsylvania, in Crawford county, containing 727 inhabitants.

**SHENAW**, a town of Austria; 4 miles S. of Kirch Schlag.

**SHENCOTTY**, a town of Hindoostan; 45 miles N.E. of Travancore.

**SHENECTADY**. See SCHENECTADY.

**SHENGANA**, a town of Hindoostan, in the Carnatic; 25 miles S.S.W. of Madura.

**SHENKAFELD**, a town of Austria; 5 miles W. of Freystadt.

**SHEN-SEE**. See CHIENSI.

**SHENSEN**, in *Rural Economy*, a term applied, in some districts, as Devonshire, to dried cow and horse-dung, which is laid up and used as fuel for the winter season.

**SHENSHIL**, in *Geography*, a town of Egypt, on the right bank of the Nile; 2 miles N. of Achmim.

**SHENSTONE**, WILLIAM, in *Biography*, a poet of celebrity, was born at Hales Owen, in Shropshire, in the year 1714. His father was an uneducated gentleman farmer, who cultivated an estate of his own called the Leafowes, which the son afterwards rendered celebrated. William received the elements of instruction from a village dame, whom he has finely described in one of his poems. After this he was sent to the grammar-school at Hales Owen, whence he was removed to that of a clergyman at Solihull, from whom he not only acquired solid learning in classical knowledge, but a cultivated taste. In 1732 he was entered of Pembroke college, Oxford, where he did not make a large acquaintance, but he was one of a few who met at each other's rooms to read and examine the best works in English literature. Here it was he discovered his poetical genius, and produced some compositions of considerable merit, and he had thoughts of taking his degrees, and proceeding to study for a profession, but coming, by the death of his father, into the full possession of his paternal property, he gave himself up to literary ease, and rural retirement, abandoning at once all intentions of active pursuits; hence his biographer justly remarks, "that nothing is more unfavourable to the exertion of those energies which lead to a useful and honourable station in society, than the early possession of a fortune just sufficient to gratify present wishes, and preclude the necessity of immediate entrance into any vigorous course of action." An acquaintance which Shenstone formed with Mr. Graves of Mickleton, in Gloucestershire,

inspired him with an affection for that gentleman's sister; but the passion of love, which, in some minds, operates as a stimulus to enterprize, seems to him to have wasted its force on plaintive elegies, and other effusions of sentimental poetry. To one species of employment, indeed, he was probably animated by his visit to Mr. Graves,—that of rural embellishment,—which he afterwards belov'd on his favourite place of the Leafowes, with a taste that conduced more to his celebrity than his comfort.

In 1737 he printed, but without his name, a small volume of juvenile poems, which obtained scarcely any notice. In 1740 he came to London, and was introduced to Doddsley, who printed his poem of "The Judgment of Hercules," dedicated to lord Littleton. This was followed by "The School-mistress," of which the heroine was the village dame already referred to. This is thought, by some very respectable critics, to stand at the head of Shenstone's compositions.

Shenstone, from this time, devoted himself to improving the picturesque beauties of the Leafowes, and sometimes exercising his pen in effusions of verse and prose. The celebrity of this place led him into expences which his fortune was unequal to, and he was perpetually under the pressure of poverty; which, with the deficiency of regular employment, and the perpetual desire of doing more, and appearing better off, than his means admitted, preyed on his spirits, and rendered him the miserable inhabitant of the Eden which his taste and genius had created. Grey has described him in the following sentence, which may in some respects be rather a caricature likeness. "Poor man! he was always wishing for money, for fame, and for other distinctions; and his whole philosophy consisted in living against his will in retirement, and in a place which his taste had adorned, but which he only enjoyed when people of note came to see and commend it." It has been thought a matter of surprize, considering his connections, that nothing was done to place him in easier circumstances. Application was said to have been made to lord Bute to procure him a pension from the privy purse, but before the wishes of his friends could be realized he died. This event took place in February 1763, when he was in the 50th year of his age: he was interred in the church-yard of Hales Owen.

Of his poetical compositions many were inserted in Doddsley's collection of original pieces; and after his death, his "Works in Verse and Prose" were published in two vols. 8vo. in 1764, and a third volume, consisting of "Letters," was published in 1769. "Of his poetry," says the critic, "the general opinion was almost uniform; it is regarded as commonly elegant, melodious, tender, and correct in sentiment, and often pleasing and natural in description, but verging to the languid and feeble, and never exhibiting either the powers of the imagination, or the energy and splendour of diction, that characterize compositions of the higher order. His prose writings display good sense and a cultivated taste, and contain just and sometimes new and acute observations on mankind."

**SHENUZAN**, in *Geography*, a town of Candahar; 42 miles E. of Ghizni.

**SHEPEY**, *Isle of*, an island within the liberty of the same, lathe of Sway, and county of Kent, England, is situated near the mouth of the river Thames, and is separated from the mainland by a narrow arm of the sea, called the Swale, which bounds it on the south, while the estuary of the Medway, and the German ocean, bound it on the west, north, and east. It is uncertain by what name this island was known to the Romans; for though Ptolemy, in his *Geography*, mentions two islands in this part of Britain by the

the appellations Toliapis and Counus, he does not describe either of them so precisely as to identify it with Shepey. Hence this subject is a matter of dispute among our most eminent antiquaries; Camden and Batteley contending for Toliapis; and Lambarde, Leland, and others, for Counus. In Saxon times it was called Sceapige, or the island of sheep, from the great numbers of that animal which were then pastured upon it, whence originated, by corruption, the name by which it is now distinguished. Baxter, in his Glossary, under the word Malata, remarks, "Vervecum Patria, or the isle of sheep, now named Shepey. This is corruptly called by the book of Ravennas, Malaca, by the Britons Vervex;" but these observations are rather conjectural than well authenticated.

The Isle of Shepey, including the small adjoining isles of Elmley and Hart, which lie at the south-east side of it, measures about 32 miles in circumference, being about 11 miles long and six broad. On the southern side the lands are flat and marshy, but the interior is diversified by hills, and the northern shore presents a range of cliffs, extending six miles in direct length. These cliffs are chiefly composed of a loose friable marl, abounding in pyrites, and in some places rising perpendicularly to the height of 90 feet. They belong principally to the three manors of Minster, Shurland, and Warden, the owners of which let them to the copperas makers, who employ the poor inhabitants to collect the pyrites, or copperas stones, which are continually washed out of the cliffs by the force of the waves, and are of various forms, as globular, oblong, &c. Their external covering is a ferruginous coat; and within they are of a striated texture, commonly radiated from a centre. The ludi Helmontii also abound in these cliffs. They are in general of a compressed form, from twelve inches to two feet and a half long, and covered with a thick crust of indurated clay. Where the clay is most tenacious, selenites are found of several varieties. Large nodules of petrified wood, retaining the appearance and grain of oak, are likewise met with in these cliffs and on the shores; also a vast number of fruits; but as these are always saturated with pyritical matter, they soon fall to pieces. Animal remains have likewise been found here of many different kinds; as the thigh-bones, tusks, and grinders of elephants; two species of tortoises; the heads, tails, and palates of fish; the teeth and vertebræ of sharks; crabs, lobsters, shells, &c.

The greatest part of this island is of an exceeding stiff clay soil, and consists chiefly of upland pastures and marsh lands. Towards the north side, however, in the parishes of Minster and Eastchurch, it is very fertile in corn, the inclosures of which are small, and surrounded with thick hedge-rows of elm. The roads throughout the island are very good during the whole year, owing to the great plenty of fine gravel found in the beach-pits, and the prospects from them are very pleasing and extensive on every side. Fresh water is very scarce, and the greatest part of it brackish, though between Eastchurch and Minster there are a few springs, which, notwithstanding they rise near the sea, the waters of them are perfectly good and fresh. The air is generally thick, and much subject to noxious vapours, arising from the large quantity of marshes in and near it. Hence, and from the badness of the water, few people of substance live in it, the inhabitants consisting in general of lookers, bailiffs, farmers, and servants. The garrison and dock of Sheerness and its environs, the reader will however of course except from this observation, where there are many gentlemen employed in the government service constantly resident. See SHEERNESS.

The water which flows between this island and the main  
VOL. XXXII.

land is called the Swale, and the two extremities of it the East and West Swale. It reaches about twelve miles in length, and is navigable for ships of two hundred tons burthen. This water seems formerly to have been accounted a part of the river Thames, and to have been the usual, as being the safest, passage for the shipping between London and the North Foreland. Accordingly Sandwich is frequently stiled by our ancient historians *Lundenwic*, or the Thames mouth, being the name given to it by the Saxons, and the town of Milton is said by them to stand on the south bank of the Thames. Leland in particular says, in his Itinerary, "that towne stands on an arm of the Tamise;" and he speaks of the point against "Quinborough entering into the mayne Tamys."

The usual passage to this island is by a ferry, called King's Ferry, for carriages, horses, cattle, and passengers. The ferry-boat is moved forward by a long cable, of about one hundred and forty fathoms, or more, which being fastened at each end across the Swale, serves to move it forward by hand. On the side opposite to the island there is a small house of stone, in the room of one formerly erected by one George Fox, who having staid a long while in the cold waiting for the boat, and being much affected by it, built it to shelter others from the like inconvenience.

The very convenient situation of the Isle of Shepey for the devastating pursuits of the Danes, occasioned it to be made their accustomed rendezvous; and they sometimes wintered here during the course of the ninth century. The inhabitants were then but few, and chiefly congregated in the neighbourhood of Minster, where Sexburga, widow of Ercombert, king of Kent, had founded a nunnery, which, after being several times plundered by the invaders, was at length, in a great measure, destroyed, and the nuns dispersed. The large tumuli in the lower or southern part of the isle, and which are termed coterets by the country people, are supposed to cover the remains of different Danish chiefs, who were slain in battle during their piratical incursions. The years which have been particularly recorded as those wherein these marauders were most active here, are 832, 849, 851, and 854; in the year 1016, king Canute is said to have collected the scattered remains of his army in this isle, after his defeat in the vicinity of Otford, by Edmund Ironside. Hasted's History and Antiquities of Kent, 8vo. 1798. Beauties of England and Wales, vol. iii. by E. W. Brayley and John Britton, 8vo. 1806.

SHEPHERD, in *Agriculture*, a labourer or other person who has the care and management of a flock of sheep. It is a business that requires much care, attention, and knowledge of the various methods of treating animals of this kind. Mr. Bannister thinks, that it is necessary to have for this employment a person who is well skilled in the nature and management of sheep, and hath been brought up in that employment from his infancy; who is sober, diligent, and good-natured; qualities essentially necessary in a shepherd, who, although he may seem to live a life of indolence, when contralled with the more laborious servants of the farm, need rarely to have a minute's time hang heavily on his hands, if he will be attentive to his business, which will furnish him with sufficient employment throughout the day, particularly in the lambing season, or where there are two flocks at work; nor will he want opportunity for the exercise of his patience and good temper in his attendance on the sheep, which are by nature animals of great obstinacy and perverseness, and which have often paid the forfeit of their lives to these innate qualities, where the shepherd was a man of morose and surly disposition. It is said that on the continent they have schools wherein young shepherds are instructed in the ne-

cessary knowledge of their business, as well as the anatomy and physiology of sheep, the food and treatment proper for them in different seasons, and the nature of their diseases, and the common operations respecting them, especially regarding the parturition of the ewes, &c. And in the General Treatise on Cattle, it is remarked, that the method of encouragement, adopted in some districts, of allowing the shepherd to possess a small flock, or as many ewes as his means will allow, is probably one of the most powerful. It gives him that steadiness appertaining to property, and is an additional and strong incentive to the attainment of knowledge in his business. A shepherd should be naturally active, both in body and mind, clear-headed and clear-sighted; such an one, for instance, as can distinguish the individual countenances of a numerous flock, and running over them with his bodily and mental eye, instantly give the exact number and condition; or perceive at a glance, a bird's nest in the thickest quickset. Fond of animals and attractive to them, the latter quality of which is well known to inhere in some persons; possessing a musical voice and shrill whistle; hardy, patient, watchful; satisfied with little sleep, and temperate in drink. It is conceived that he ought never to be suffered, if he professes, to practise physic, nor any but the most easy and common operations, a farce that too often ends in a tragedy; for if of two evils we ought to choose the least, the office of medical practice had better devolve on the malter. And for his comfort in the severe weather, in some situations, the moveable wooden house on wheels may be of use. Also that he ought to be clad during winter, with substantial woollen next his skin, from his feet upwards, as the best defence against those rheumatic ails to which he must be necessarily subject; and he should always go provided with the instruments proper to his profession, ready for immediate occasions, namely, scissors, knife, steel, sheam, false-box, &c. And in folding, as the shepherd will have the flock perpetually under his eye, the first writer thinks, he will be capable of judging with certainty and precision respecting the state of every individual, so that the earliest remedy may be applied to every disorder, and such sheep may be turned out of the fold which are found not to be able to go through their work without manifest injury to their health; and if a sheep or lamb be seized with a dangerous and incurable malady, to kill and dress it immediately; for it is one part of the business of a shepherd to be so far skilled in the butcher's trade, as to be able to slaughter, flea, and dress a sheep on occasion. Farther, that a good shepherd will be careful that his flock be driven late to fold of an evening, and released early in the morning from their confinement, in order that they may enjoy the coolest parts of the day on the food. He will be cautious that they are allowed a sufficient time to graze in the uplands previous to their being driven into the fold, that they may retire to rest with full bellies, by which the quantity of the dung and urine will be considerably augmented. He will likewise be careful in reviewing the hurdles, and providing that these are fixed in the ground, lest by any accident they should be thrown down during the night, and the flock by these means get into mischief, or intermix with other sheep; he will count his sheep regularly every evening when he drives them to the fold, and take a fresh tale in the morning, when he turns them on their feed; he will, previous to dismissing them from the fold, worry them gently round the same, in order to cause them to dung and stale plentifully, that the manure may be left in the field, otherwise the greatest part of the trundles will be dropt on the road, or carried on to the marsh, where lying thin, this dressing can do but little service, and where in truth it is not wanted; he will bestow

a particular attention on every individual in his flock, and for those which shew any appearance of being stung by the fly, he will be prepared with a pair of sheers to clip away the wool from the part, and having taken out the maggots, will anoint the place with a mixture of train-oil and brimstone; but if slightly attacked, he will destroy the maggots by strewing on them powder of white lead; and if any of the flock should haply break with the scab, a disorder to which folding sheep are continually subject, and which seldom fails to shew itself in the spring and fall, he will be provided with a proper remedy to keep it under, and prevent the contagion from spreading. See SCAB.

It is likewise thought, that one shepherd will be able to look after three hundred sheep.

In respect to the necessity of a dog, as an assistant to the shepherd, Mr. Lawrence thinks, that it has of late very rationally become a question among the most intelligent sheep-masters: it may probably be thus settled,—there can be no occasion for such aid, nor any necessity for incurring the danger of it, amidst convenient inclosures, or where quiet breeds of sheep are kept, and where it is made an object to render them tame and docile: and if upon extensive wastes and mountain districts, the service of dogs cannot well be dispensed with, it ought to be made a main point, that they be trained early to a kindness for the sheep, and to view them rather as their companions, than their prey; a thing which he knows by experience to be most easy; and he also knows that such dogs are infinitely of the greater use, as the sheep, far from dreading or shunning, will run to them, in case of need, for protection; and he has often witnessed the caresses and gambols of these and the lambs, with a delight which he never experienced in the combats of animals.

SHEPHERDS of Egypt, *Shepherd kings*, or *royal Shepherds*, in *Ancient History*, the denomination of a class of inhabitants of a part of Egypt, concerning whose origin, place of abode, and migration, ancient and modern writers have entertained different opinions. Some sketches of their history will be found under the articles AURITÆ, CUSH, DISPERSION of Mankind, and EGYPT. The learned Bryant has published, besides several notices that occur in his "Analysis of Ancient Mythology," an elaborate "Dissertation" on this subject. Differing from others concerning the situation of the land of Goshen, (see GOSHEN,) he conceives it to have been the Nome called the Arabian, from the Arabian shepherds who had formerly settled in those parts, and held them for many years, and denominated by the LXX, Γεσημ της Αραβιας. The province of Arabia, says this author, was one of the three most remarkable nomes, the other two being those of Bubaitus and Heliopolis. These three nomes were contiguous to each other, and towards the summit of Lower Egypt. The nome of Heliopolis, according to his statement, was a Mediterranean district; and consequently the two provinces, or that of Phacusa (*i. e.* the Arabian nome), and that of Bubaitus, that are always mentioned with the former, were so likewise. Phacusa, mentioned by Strabo only as a village, was the province at whose summit the Nile was first divided, where stood the city of Cercasora. It was called the Arabian nome for the reason above-mentioned, and had for its metropolis Phacusa, and the places situated upon its borders were Babylon, Heliopolis, and Heroum. From Syncellus we learn, that Egypt had been in subjection to a three-fold race of kings, who are termed the Auritæ, the Meitæi, and the Egyptian. The Auritæ were the Arabian shepherds and their kings, who reigned here a considerable time, maintaining themselves by force; till, after many struggles, they

they were finally expelled by the natives. According to Manetho, the whole body of this people bore the appellation of Hukfos, that is, royal shepherds; the first syllable, in the sacred dialect, signifying a king, and the latter, in the popular language, signifying a shepherd; and by a composition of these two was formed the word Hukfos. These people are said to have been Arabians. Josephus further informs us from Manetho, that the shepherds maintained themselves in Egypt 511 years. At last the people of Upper Egypt rose in opposition to them, and after some time expelled them the country. However, on their departure, they were afraid of going towards Assyria, and therefore resorted to the country called afterwards Judea, and built Jerusalem. We learn also, from the same authority, that another class of people sojourned in Egypt in the reign of Amenophis; and that they were treated as slaves by the prince of the country, because they were infected with the leprosy. As their number very much increased, he employed them in the stone quarries that lay on the east side of the Nile, in company with some of the Egyptians. Upon a remonstrance afterwards made to him, he granted them for a retreat the city of Abaris, where the former shepherds had resided, that now lay desolate. The people belonging to each of the two classes now mentioned were esteemed shepherds: the first shepherds were lords and conquerors; the others were servants, to whom was assigned the city which the former had evacuated. The latter were Israelites, as appears from the name of their leader and lawgiver, Moses; and the former were Arabians, who are said to have come from the East: and they are, without doubt, the Auritæ, who founded the city Auris or Abaris, which is no other than the city אור, Ur or Aur, signifying light and fire, of which element the Auritæ must have been worshippers, as all the Arabians were. Their chief god was Alorus, (Al Orus,) the god of fire. Accordingly the shepherds were called Auritæ from the chief object of their worship, and their kings were styled priests of Alorus, or, according to the Greeks, priests of Vulcan. Hence it has been inferred that they came from Babylonia, a country that lay due east from Egypt, which country was the original seat of the genuine Arabians, and the true source whence their religion flowed. The two principal cities of that country were Ur or Aur, and Babylon: in memory of which they built two of the same name in Egypt. Wherever they resided, they introduced the Tzeba Schanain, or Zabian worship, together with the worship of fire. Hence we are informed by Herodotus, that Vulcan was particularly honoured at Heliopolis and Memphis, which places they are said to have built. The true name of these people, says Bryant, who were called by the Greeks and Romans Arabians, was Cushan or Cusæans, the same that they gave to the province where they settled. (See CUSH.) These strangers, therefore, who settled in Egypt, were no other than the Cusæans; and they have been styled Arabian shepherds, because all the primitive Arabians were Nomades, or shepherds. These people becoming lords of the country, undoubtedly chose that part which was the most eligible, and their profession would lead them to the best land for pasturage; in respect of which Goshen had not its equal. For it was part of the πῶλον Αιγυπτῆς, the rich champaign of Egypt; so that this circumstance among others would induce one to think that they settled here. This is confirmed by the worship which they settled in these parts; the cities they built; and the names which they bequeathed to the province. According to the Mosaic account, the land of Goshen is repeatedly said to be in the land of Egypt, "in the best of the land;" and yet the LXX call it

Γῆσιμα τῆς Αρβίαις, which could be owing to no other reason besides its being the land of Cushan, (Goshen,) which was interpreted Arabian; for in Arabia it was not situated. Hence it has been concluded, that the place where the children of Israel resided in Egypt was the principal Arabian nome, at the extreme and highest part of Lower Egypt, called Cushan.

This was the land to which the children of Israel succeeded, after it had been abandoned by its former inhabitants; but it is uncertain at what interval. It appears to have been an unoccupied district; and as it was the best of the land, there is no accounting for its being unoccupied but by the secession of the Cusæans, whose property it had lately been. Accordingly Manetho expressly affirms, that the second shepherds succeeded to the places which had been deserted by the former; and he moreover says, that the city Abaris, which had been built by the first shepherd king, was given to those of their body who were employed in the quarries.

Bryant suggests, that the migration of the shepherds was about the time of Serug or Nahor: and this is the time when archbishop Usher supposes it to have happened, who refers it to the year of the world 1920, according to the Hebrew computation, in the 101st year of the life of Serug, the 7th from Noah, and in the 42d year of Terah, 88 years before the birth of Abraham. Bishop Cumberland supposes that the shepherds invaded Egypt A. M. 1937, in the time of the same patriarchs, according to the Hebrew chronology. Our author has alleged several arguments to prove, that the Arabian shepherds were distinct from the Israelites, and prior to them. When the Arabians came into Egypt, they are said to have been 240,000 in number, whereas the Israelites were but 70 persons. The former took possession by force, the latter were invited, and had a grant of all that they possessed. The one held the people in slavery; the others were themselves enslaved. The Arabians were driven out of the land; the Israelites were not suffered to depart. See Bryant's Observations and Inquiries, &c. Cont. 1767.

SHEPHERD'S ISLANDS, in Geography. See *NEW HERRIDES*.

SHEPHERD'S DOG, a variety of the common dog, used in guarding flocks, or driving herds of cattle. See *DOG*.

SHEPHERD'S NEEDLE, or *Venus's Comb*, in Botany. See *SCANDIX*.

SHEPHERD'S POUCH, *Bursa pastoris*, a common weed in most parts of England, which propagates itself so fast by seeds, as not to be easily cleared where they are permitted to shed; for so fast do the seed ripen, and the plants come up, that there are commonly four or five generations of them in a year; they cannot, therefore, be too carefully rooted out of a garden or field. It is early, and lasts most part of the year. It may be destroyed by frequent ploughing, and preventing its going to seed. In the Linnæan system, this is a species of the *thlaspi*.

This is an officinal plant; its juice has been reputed astringent and vulnerary, and as such is used against hæmorrhages, dysenteries, diarrhœas, &c.

The country people apply it to cuts and fresh wounds, and some hold it of great virtue when made up into a cataplasm, and applied to the wrists against tertians and quartans; but Dr. Lewis observes, that he could perceive no pungency or astringency, either in the leaves of this plant, or in the extracts made by water and rectified spirit, and that a decoction of them strikes no degree of blackness with solution of chalybeate vitriol. Hence he infers, that there seems to be no foundation for the strong styptic virtues, for which this herb has been generally recommended by writers

in the materia medica, or for the acrid inflammatory power which some (probably misled by its botanic affinity with mustard, and some other acrid vegetables) have ascribed to it. Lewis's Mat. Med.

SHEPHERD'S *Staff*, or *Shepherd's Rod*. See TEAZLE.

SHEPHERDSTOWN, in *Geography*, a post-town of America, in the state of Virginia, and county of Jefferson, on the S. side of Patowmack river. Its situation is agreeable and healthy, and the neighbouring country fertile and well cultivated. It is said to contain 1033 inhabitants, chiefly of German extraction.

SHEPHERDSVILLE, a post-town in Bullet county, Kentucky; 640 miles from Washington.

SHEPPECK, in *Agriculture*, the provincial name of a prong or sort of hay-fork, employed in some places.

SHEPPEY, in *Geography*. See SHEPEY.

SHEPREVE, JOHN, in *Biography*, an English poet, was born in Berkshire, and educated at Corpus Christi college, Oxford, where he took his degrees in arts, and became Hebrew professor about the year 1538. He had a most surprising memory, and was one of the most learned men in his time. He died in the year 1542. His works are "Summa et Synopsis Novi Test." &c.; "Hippolytus Ovidianæ Phædræ respondens," &c. Wood.

SHEPTONMALLETT, in *Geography*, a market-town in the hundred of Whitestone and county of Somerset, England, is situated about five miles E. from the city of Wells, and 115 W. by S. from London. This town has been long celebrated for its manufacture of woollen cloths and knit stockings, which affords employment to upwards of 2000 persons resident in the town or its vicinity. Edward II. granted a charter for a market to be held here on Monday, weekly; but it is now kept on Friday; besides which there is an annual fair, called Silver-street fair, which takes place on the 8th of August. The market-place is remarkable for a very curious stone cross, which appears, from an inscription upon it, to have been erected in the year 1500, by "Walter Bucklond and Agnes his wyff." It consists of five arches, supported by pentagonal pillars, with an hexagonal column in the centre. From the roof, which is perfectly flat, rises a lofty pyramidal spire, adorned with Gothic niches, and crowned with an oblong entablature, on which are represented figures of our Saviour on the cross between the two malefactors; also those of several faints. Lands of considerable value are appropriated for the repair of this singular structure. The church here is a large and handsome edifice in the pointed style of architecture, and composed of a nave, chancel, north and south side aisles, and transept, with a tower at the west end, ornamented with effigies in niches of the Virgin Mary, St. Peter, and St. Paul. The pulpit and font are each cut out of one solid stone, and from the rudeness of their workmanship would seem to be of very great antiquity. In two of the windows are some remains of painted glass, displaying the mutilated effigies of knights Templars, said to represent the two Williams Mallet, who had commands in an expedition to the Holy Land during the reign of king Henry II. The monuments in this church are numerous, but none of them are particularly remarkable, either for their style of execution, or for the character of the persons they commemorate.

Shepton Mallet, in ancient times, formed part of the manor of Pilton, which king Ina gave to the abbey of Glastonbury, A.D. 705. At the time of the Conquest it was held from the abbot by Roger de Curcelle; but soon afterwards passed into the possession of the barons Mallet, from whom it derived the latter part of its name. After a

variety of changes, this manor was divided into two moieties, one of which came to the crown, and was annexed to the duchy of Cornwall, to which it still belongs. The other moiety became the property of the family of Sherston.

Shepton Mallet is noted as the birth-place of three men of distinguished talents and learning; viz. Hugh Inge, D.D. archbishop of Dublin, and chancellor of Ireland, who died in 1528; Dr. Walter Charleton, an eminent physician, and author of *Chorea Gigantum*, or an account of Stonehenge, who died in 1707; and Simon Browne, a learned dissenting minister, celebrated for his controversial writings against Woolton and Tindal, who died in 1732.

The parish of Shepton Mallet is of small extent, but populous, containing, according to the parliamentary returns of 1811, 1129 houses, and 4638 inhabitants. Within its bounds are situated the county Bridewell, and a large parish workhouse. The History and Antiquities of the County of Somerset; by the Rev. J. Collinson, F.S.A. 4to. vol. iii. Bath, 1791.

SHERARD, WILLIAM, in *Biography*, a very learned and munificent botanist, on whom the titles of prince and Mæcenas of botany have been, more justly than usual, bestowed, was the son of George Sherwood, (for so it seems the name was written by the father,) of Bulby, in Leicestershire. He was born in 1659; educated first at Merchant Taylors' school, and then at St. John's college, Oxford, where he entered in 1677. He subsequently became a fellow of this college, and took the degree of Bachelor of Law, December 11, 1683. Being appointed travelling tutor, successively, to Charles, afterwards the second viscount Townshend, and to Wriothesley lord Howland, son of the murdered lord Ruffel, who in 1700 became the second duke of Bedford, Sherard made two successive tours through Holland, France, Italy, &c. returning from the last, as we presume, not much before the year 1700, when his last-mentioned pupil was twenty years old. Dr. Pulteney supposes him to have come back in 1693, led perhaps by the date of Ray's *Sylloge Stirpium Europæarum*, printed in 1694, to which Sherard communicated a catalogue of plants gathered on mount Jura, Saleve, and the neighbourhood of Geneva. These were probably collected in his first journey; for it should seem by Collins's Peerage, that the lord Howland, so created on account of his union with the heiress of the Howland family, was married to her in May 1695, when he was little more than fourteen years of age. He was made a peer June 13, 1695; "after which," says Collins, "he travelled into France and Italy." So youthful a bridegroom was, doubtless, best in the hands of his tutor, in a distant country from his, still more youthful, spouse. The subject of our memoir is said to have fulfilled his trust to the satisfaction of both the noble families who confided in him. His visit to his friend sir Arthur Rawdon, at Moira, in Ireland, was apparently made in the interval of these two foreign journies. Long before either of them, he had travelled over various parts of England, and proceeded to Jersey, for the purpose of botanical investigation; and the fruits of his discoveries enriched the publications of the illustrious RAY; see that article.

Botany was ever the prominent pursuit of Sherard in all his journies. He cultivated the friendship and correspondence of the most able men on the continent, such as Boerhaave, Hermann, Tournefort, Vaillant, Micheli, &c. He is universally believed to have been the author of a 12mo. volume, entitled *Schola Botanica*, published at Amsterdam in 1689, and reprinted in 1691 and 1699. This is a systematic catalogue of the Paris garden. Its preface, dated London, Nov. 1688, is signed S.W.A., which the French

French writers have interpreted Samuel Wharton, *Anglus*, under which name the book occurs in Haller's *Bibliotheca Botanica*, v. 1. 643. But as no one ever heard of such a botanist as Wharton; and the preface in question displays the objects and acquisitions of one of the first rank, who could certainly not long remain in obscurity, the above initials are presumed to mean William Sherard, to whom alone indeed, with or without a signature, that preface could belong. Its writer is described as having attended three courses of Tournefort's botanical lectures, in 1686, 87, and 88, all which years, he says, he spent at Paris. In the summer of 1688 he describes himself as having passed some time in Holland, collecting specimens of plants from the rich gardens of that country and getting them named by professor Hermann himself, who allowed him to peruse the manuscript rudiments of his *Paradisus Batavus*, to examine his herbarium, and to compose a *Prodrômus* of that work, which is subjoined to the little volume now under our consideration. All this can apply to Sherard only, who became the editor of Hermann's book itself, and who in its preface, dated from Geneva in 1697, appears under his own name, and speaks of himself as having long enjoyed the friendship and the communications of that eminent man, whose judgment and talents he justly commemorates, and of whose various literary performances, as well as of his botanical principles, he gives an account. Dr. Pulteney conceives this preface to have been written during a third tour of its author to the continent; but we presume him to have then been with the young lord Howland, and consequently on his second tour only.

Sherard communicated to the Royal Society, in 1700, a paper relative to the making of Chinese or Japan varnishes, which is printed in the Philosophical Transactions, v. 22. The information which it contains was sent by the Jesuits to the grand duke of Tuscany, and probably obtained by our author at Florence.

He now entered on a more public walk of life, becoming one of the commissioners for sick and wounded seamen at Portsmouth, and about the year 1702, or soon after, was sent out as British consul to Smyrna. Here his botanical taste met with fresh gratification; nor was he neglectful of other curiosities of science or literature. He visited the seven churches of Asia, copied several ancient inscriptions, and communicated to the Royal Society an account of the new volcanic island, near Santorini, which rose out of the sea May 12, 1707.

Botany, however, continued to be his leading object. He had a villa at Sedekio, near Smyrna, where he could with the more ease resign himself to the contemplation of plants, and where he began that great herbarium of which we shall speak hereafter. Hasselquist visited this spot, with the devotion of a pilgrim, in the spring of 1750. He saw the house, with a small garden laid out by Sherard, but not enriched at any great expence, nor stored with extensive collections of exotics. Many of the latter indeed might, in the course of thirty-two years, have disappeared. Whatever specimens Sherard could obtain from Greece, and the neighbouring countries, he here carefully preserved; and being well aware of the insufficiency of Bauhin's *Pinax*, as a clue to the botanical knowledge then in the world, he is said to have here formed the project of continuing it, and even to have made some progress in that arduous undertaking, before he returned to his native country in 1718. Soon after his return he received at Oxford the degree of L.L.D.

In 1721 Dr. Sherard revisited the continent. Vaillant was now in a declining state of health, and died in May

1722. Previous to his decease he concluded, through the mediation of Sherard, the sale of his manuscripts and drawings of Persian plants to Boerhaave, who published in 1727 the splendid *Botanicon Parisiense*. This work, though not free from imperfections in the distribution of its materials, would doubtless have been far less correct, but for the superintendance of Sherard, who passed a summer with Boerhaave in revising the manuscript. Our great botanist had already rendered a more important service to his favourite science by bringing with him from Germany, in August 1721, the celebrated DILLENIUS (see that article). By a comparison of dates, it appears that Sherard made several visits to the continent. He went from Paris to Holland in 1721, and thence with Dillenius, the same year, to England. He stayed some time with Boerhaave again in 1724, or perhaps 1725. We know not precisely when or where it happened that he was, like Linnæus in Norway, in danger of being shot for a wolf, or a thief, by some half-humanized rustic, akin to the thief-takers and Oxfordshire justice, who seized upon another illustrious botanist, of our time, as a highway-man.

What principally attached Sherard to Dillenius, was the similarity of their tastes respecting those intricate tribes of vegetables, now termed cryptogamic. To these the attention of both had long been directed, and hence originated the cultivation, which this line of botanical study has received, from that period, in England and Germany. This taste, however, was not exclusive; for these friends and fellow labourers left no department of botany unimproved. James Sherard, seven years younger than his brother, who had acquired opulence by medical practice, first as an apothecary, and then as a physician, in London, had a great fondness for the same pursuit, and reared at his country seat at Eltham, a number of exotic plants, from every climate. Hither the more learned subject of our present article frequently resorted. He had acquired affluence by his public appointments, but his style of living was simple and private. Devoted to the cultivation of knowledge in himself, and to the diffusion of that of others, he lent his aid to all who required it, without coming forward conspicuously as an author. He assisted Cateby with information and with money, to bring out his *Natural History of Carolina*, though neither that work, nor the *Hortus Elthamensis* of Dillenius, appeared till some time after his decease, which happened on the 12th of August, 1728, when he was 69 years of age. Of the place of his interment we find no mention. His brother died Feb. 12, 1737, aged 72, and is buried in Evington church, near Leicester, with his wife, whose maiden name was Loekwood, by whom he had no children.

The most ostensible and splendid service to botany, though it for a long time yielded but little fruit, was rendered by the will of Dr. William Sherard, who left 3000*l.* to found and support a botanical professorship at Oxford, of which we have spoken under the biographical article DILLENIUS. He bequeathed to this establishment his choice botanical library, his ample herbarium, and the manuscript of his *Pinax*, the completion of which he intended should be one of the objects and duties of the new professor. We have already expressed our doubts whether the failure of the latter, in this point, were any great loss to science. Nevertheless, the manuscript, as Sherard left it, would probably have been a great acquisition to the world, and might still be worthy of publication. Dillenius accomplished more appropriate, and perhaps more difficult designs; but every scientific object slept with his successor for forty years. Sherard has sometimes been blamed for excluding clergymen from

from his professorship, and it is usual to hear a complaint at Oxford, that this order of men has no *interest* therein. If by interest is meant the acquisition of a very moderate stipend, which only one can enjoy, the complaint is just: but surely the more important interest of a whole university consists in having this, or any other, science taught in the best manner. Sherard therefore would have done much more wisely, instead of limiting the appointment at all, to have left it open, like the Cambridge professorship and garden, to all the world; and to have placed the choice in the hands of those who would perceive their own advantage, and probably feel some sense of duty, in not making any professorship a sinecure or a job.

The herbarium of Sherard is perhaps, except that of Linnæus, the most ample, authentic, and valuable botanical record in the world. In it may be seen original specimens from Tournefort, and all the writers of that day, named by themselves, accompanied by remarks, or by queries scarcely less instructive. He collected also copies of original drawings, from botanists whose specimens were not to be had, such as Plumier. The most rare, and even unique, books are to be found in his library, as the first volume of Rudbeck's *Campi Elyfii*. (See RUDBECK.) All these precious collections are still in good preservation, though the noble stone building, originally constructed to receive them, was sacrificed a few years since to public convenience, that the adjoining street might be widened.

The name of Sherard has been commemorated by Vaillant, in some plants referred by Linnæus to *Verbena*. Dillenius established a *Sherardia*, which has remained; see the next article. Paltenev's Sketches of Botany. Haller's Letters, and Bibl. Bot. Aikin's Gen. Biog. S.

SHERARDIA, in *Botany*, so named by Dillenius, in honour of his munificent and learned patron William Sherard. (See the last article)—Dill. Giff. append. 96. t. 3. Linn. Gen. Pl. 50. Schreb. 67. Willd. Sp. Pl. v. 1. 574. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 171. Prodr. Fl. Græc. Sibth. 86. Ait. Hort. Kew. v. 1. 234. Juss. 196. Lamarck Illustr. t. 61. Gärtn. t. 24.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Stellate*, Linn. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, small, with six teeth, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrical, various in length; limb flat, in four acute deep segments. *Stam.* Filaments four, inserted into the top of the tube, between the segments of the limb; anthers roundish, two-lobed. *Pist.* Germen inferior, oblong, two-grained; style thread-shaped, divided at the upper part; stigmas blunt. *Peric.* none. Fruit oblong, crowned, separating lengthwise into two parts. *Seeds* two, oblong, convex at the outside, flat on the other, each crowned with three points.

Ess. Ch. Corolla of one petal, funnel-shaped, superior. Seeds two, naked, each crowned with three teeth.

1. *S. arvensis*. Blue Sherardia, or Little Field Madder. Linn. Sp. Pl. 149. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 891. Curt. Lond. fasc. 5. t. 13. Fl. Dan. t. 439. (*Asperula flore carneo, acuto folio*; Barrel. Ic. t. 541.)—All the leaves whorled. Flowers terminal.—Native of cultivated or fallow fields, throughout Europe, from Sweden to Greece, flowering all summer long. The root is annual, fibrous, small. *Herb* generally hairy. *Stems* several, branched, leafy, angular, spreading in every direction, from three to five inches long; most slender at the base. *Leaves* spreading, mostly six in each whorl, elliptical or obovate, pointed, entire, roughest at the edges and keel. *Flowers* from four to six or eight, in a little ter-

minal umbel, enveloped in the uppermost whorl, which consists of more leaves than the rest. *Calyx* of two three-cleft acute leaves, afterwards enlarged, and forming a crest, or crown, to each seed. *Corolla* purplish-blue, with a slender tube, much exceeding the calyx.

2. *S. muralis*. Wall Sherardia. Linn. Sp. Pl. 149. Willd. n. 2. Sm. Fl. Græc. Sibth. v. 2. 13. t. 115. (*Galium murale*; Allion. Pedem. v. 1. 8. t. 77. f. 1. *G. minimum, seminibus oblongis*; Buxb. Cent. 31. t. 30. f. 2.)—Stems diffuse. Leaves four in a whorl, or in pairs, spreading. Whorls two-flowered. Stalks of the fruit reflexed.—Native of old walls, and rocks, in Italy and the Levant. Found in Crete by Dr. Sibthorp. Annual, about the size of the former, decumbent, and rough, but the leaves are smaller, sometimes six, sometimes but two, usually four, in a whorl. *Flowers* axillary, opposite, minute, shorter than the leaves, stalked. *Corolla* yellow, with a short tube. *Fruit* reflexed, of two hispid, oblong seeds, starting from each other in the middle, meeting at top and bottom, their crown, or *calyx*, hardly discoverable.

3. *S. erecta*. Upright Sherardia. Sm. Fl. Græc. Sibth. v. 2. 14. t. 116. (*Asperula muralis verticillata minima*; Column. Ecphr. 302. t. 300. *A. verticillata luteola*; Bauh. Pin. 334.)—Stems erect. Leaves four in a whorl, or in pairs, deflexed. Whorls many-flowered. Fruit nearly erect. Native of rocks and walls, in Italy and the Archipelago. Annual, erect, and more slender than the last, a span high. The shorter deflexed leaves, numerous flowers, and erect fruit, distinguish this species clearly, though Linnæus confounded its synonyms with his *muralis*. The crown of the seeds is equally obscure in both, and the habit of the plants answers better to that of the genuine *Valantia*, though the fructification differs. They but ill agree with *Sherardia*; yet their fruit will not allow them to be referred to *Galium*.

4. *S. fruticosa*. Shrubby Sherardia. Linn. Sp. Pl. 149. Willd. n. 3. Swartz. Obf. 46.—Leaves four in a whorl, linear-lanceolate, revolute. Stem shrubby.—Gathered by Oibeck in the island of Ascension. The stem is woody, branched, leafy, straggling or prostrate, and the whole plant has the aspect of *Ernodea montana* (see ERNODEA); but is distinct. Leaves an inch long, rather downy. *Calyx* of only four teeth. *Corolla* white, as long as the germen. Swartz justly observes, that this species but ill accords with *Sherardia*, being intermediate, as it were, between *Diodia* and *Spermacoce*.

SHERARDIA is also a name given by Pontedera to the genus of plants, called by Linnæus *galenia*.

SHERARIB, in *Geography*, a town of Africa, in Bergoo; 115 miles S.W. of Wara.

SHERAVEND, a town of Persia, in the province of Ghilan, on the Caspian sea; 20 miles S. of Altara.

SHERBET, or SHERBIT, a compound drink, first brought into England from Turkey and Persia, consisting of fair water, lemon-juice, sugar, amber, and other ingredients.

Another kind of it is made of violets, honey, juice of raisins, &c.

The word *sherbet*, in the Persian language, signifies *pleasant liquor*.

SHERBORNE, or SHERBOURNE, anciently called *Sareburn*, in *Geography*, a market-town and parish in the hundred of that name, county of Dorset, England, is situated in the vale of Blakemore, near the borders of Somersetshire, at the distance of 16 miles W. from Shaftesbury, 18 N. by W. from Dorchester, and 117 W.S.W. from

from London. It is a town of very high antiquity, but its origin is not precisely ascertained. Baxter contends that it was the Arianus, or Aranus of Ravennas, deriving its name from "Arian Uife, Argentus Fluxus Aquæ," or "Fons Clarus." This opinion, however, is rendered extremely doubtful, by the total absence of all those appearances which almost invariably characterize the cities of British or Roman towns. It seems, therefore, more probable that it had its commencement in Saxon times, and germinated from a religious house, founded here soon after the conversion of the Saxons to Christianity. This monastery was richly endowed by several of the kings of Wessex, particularly by Cenwalch, and the great Alfred. After the Conquest, it was raised to the rank of an abbey, and the abbots were esteemed spiritual barons, and in consequence were frequently summoned to assist in the parliament or great council of the nation. At the dissolution, its revenues were rated, according to Speed and Dugdale, at 61*l.* 1*4s.* 7*½d.* *per annum.*

Sherborne was further distinguished, in ancient times, as the seat of an episcopal see, having been constituted such by king Ina, on the division of the bishopric of Winchester, A.D. 704. The first bishop of this diocese was Aldhelm, nephew to Ina, who is reported to have been a man of extraordinary talents, and a great benefactor to the see. His successors have been differently named by different writers, so that much uncertainty prevails respecting them. The most probable view of the subject, however, is, that they were twenty-five in number, and conjointly presided a period of 366 years. The most celebrated among them was Aelf Menevensis, who wrote the life of Alfred the Great, and assisted him in his literary pursuits. In his time the see of Sherborne comprehended the counties of Dorset, Bucks, Wilts, Somerset, Devon, and Cornwall; but in 904, shortly after his death, the three latter counties were separated from it, and united to other bishoprics, by a bull of pope Sergius III. Herman, the 26th bishop, attempted to remove the seat of the bishopric to Malmesbury, but his intentions were thwarted by Godwin, earl of Kent, and the monks of that abbey. He succeeded, however, in effecting its removal some years afterwards, *viz.* in 1075, to Old Sarum, in consequence of the edict of the council at London, which directed that all bishops' sees should be transferred from obscure places to the most important town in each diocese. See SALISBURY.

From the great eagerness of Herman to quit Sherborne, it might reasonably be inferred that it was become a town of much less extent and importance than it was under his predecessors. Accordingly such is the fact, and the circumstance is easily accounted for; it being stated by historians, that it was laid in ashes by the Danes, under king Sweyn, during one of his vindictive excursions through this part of the kingdom. Besides, both Matthew of Westminster and William of Malmesbury describe it "as a small street, in which was nothing agreeable in number of inhabitants, or pleasantness of situation; and that it was matter of reproach and wonder that an episcopal seat had continued there so long." In this situation it appears to have remained for several centuries; but in the time of Leland it had recovered itself very considerably, as we find Sherborne mentioned in his Itinerary as the most frequented town in the county, and that in which the woollen trade was turned to the best account. After his time, however, this branch of business very much decreased; and the manufacture of buttons, haberdashery wares, and bone-lace, introduced in its stead. These trades have also decreased, and

now the silk and linen manufactures constitute the principal employment of the inhabitants.

Sherborne, though neither a borough by charter nor prescription, on one occasion sent members to parliament, in the reign of Edward III. At that time the assizes were regularly held here; but since the reign of his successor, that practice has only been occasional, as in case of epidemical disorders, or otherwise. The general quarter sessions for the peace, however, are still held here once a year, on Tuesday after the close of L. ter. The market-day here is Saturday, weekly; and there are fairs annually on Wednesday before Holy Thursday, 16th and 18th July, and the first Monday after 10th October.

The church of Sherborne, which is the only public building within the town of any importance, is a large and magnificent structure. It is built in the form of a cross, and entirely of free-stone. The original edifice was the work of bishop Aldhelm. But no part of that building probably now remains, as it has undergone frequent alterations, and in the time of king Henry VI. was almost wholly rebuilt. Hence, though displaying various styles of architecture, the greater part of it is in the pointed style of that age. The most material exceptions to this remark are the pillars supporting the tower, the south porch, and the chapel of our Lady, all of which are of early Norman origin, and the large lancet window at the eastern end of the chapel north of the chancel, which, with some smaller fragments in other parts, seem to be of the same date with Salisbury cathedral, *viz.* about the year 1220. All the later parts of the church are richly ornamented with tracery work, vine leaves, and flowers. The piers between the windows on each side are supported by light flying buttresses stretching over the side aisles. The roof is of stone, and supported by numerous groins springing from the side aisles; and between the tracery work is a number of shields bearing different arms, with roses, portcullises, and cut devices. This church was made parochial after the dissolution of the abbey, to which it previously belonged. It contains the ashes of many persons of distinction, and among others those of Ethelbold, king of Wessex, and his brother Ethelbert. The only modern monuments of note are those of John, earl of Bristol, who died in 1698, and of a son and daughter of William, lord Digby. On the latter are inscribed the following beautiful lines by Pope.

"Go, fair example of untainted youth,  
Of modest reason, and pacific truth;  
Compeld in suffering, and in joy sedate,  
Good without noise, without pretension great.  
Go, just of word, in every thought sincere,  
Who knew no wish but what the world might hear.  
Of gentlest manners, unaffected mind;  
Lover of peace, and friend of human-kind.  
Go, live, for heaven's eternal year is thine;  
Go, and exalt thy mortal to divine.  
And thou, too close attendant on his doom,  
Blest maid, has hasten'd to the silent tomb,  
Steer'd the same courte to the same quiet shore;  
Not parted long, and now to part no more;  
Go, then, where only bliss sincere is known,  
Go, where to love and to enjoy is one.  
Yet take these tears, mortality's relief,  
And, till we share your joys, forgive our grief.  
These little rites, a stone and verse, receive;  
"Tis all a father, all a friend can give."

These lines, as printed in the different editions of Pope's works, vary very materially from the original

Besides

Besides the established church, there were formerly in Sherborne two meeting-houses for dissenters; but at present there is only one, situated in Long-street. The other public structures here are the market-house, the work-house, an alms-house, and a free grammar-school. The alms-house was formerly a religious hospital dedicated to St. Augustine, and has a chapel attached to it, which appears to have been erected in the fifteenth century, and contains a very curious ancient painting upon oak in high preservation. This picture consists of three pieces, representing three of our Saviour's most remarkable miracles, and is characterized by Mr. Hutchins, in his History of Dorsetshire, as "very beautiful, and evidently executed by a masterly hand." The free grammar-school was founded and endowed by king Edward VI., and the government of it vested, by charter, in twenty principal inhabitants of Sherborne. At present, there are two masters attached to this school, who must be clergymen, and graduates of one or other of the universities. The buildings occupy the site of part of the ancient abbey, some considerable portions of which are still standing. The plan of education adopted here is similar to that of Eton. There are likewise in Sherborne two charity-schools on a contracted scale, three benefit societies, two for men, and one for women; and an institution of rather an uncommon kind, called the Green Girls' Society, which, from its excellent tendency, deserves to be more generally adopted. It was established in 1771. The members pay into it a small sum weekly, and wear, till they arrive at a certain age, green gowns and straw hats. When a girl attains the age of eighteen, she is at liberty to leave it, and if married before she is twenty-five, is entitled to 1*l.* on her wedding-day, and 1*l.* on the birth of her first child. If unmarried till twenty-five, she is then entitled to the first sum, provided she has lived a sober and virtuous life, otherwise her claims are forfeited to the society. The founder of this institution was the late Mr. John Toogood.

The parish of Sherborne extends about three miles and a half in length, and two miles and a half in breadth, and contains, according to the population census of 1811, 597 houses, and 3370 inhabitants, of whom above 2000 reside in the town. The late eminent Dr. Joseph Towers is generally stated to have been born at Sherborne, but we know from authority that he was not even a native of the county.

In a hamlet, or suburb called Cattleton, about half a mile eastward from the town, stood the ancient castle of Sherborne. This fortress was built by Roger, third bishop of Salisbury, and occupied a rocky eminence on the north bank of the river Ise. The area contained within the deep fosse, which inclosed the whole works, measured about four acres in extent. Few castles surpassed this in strength and magnificence of structure. It was one of the three, erected by the same bishop, which William of Malmesbury mentions among the wonders of the world. It was of an octagonal form, and had seven courts, with strong battlements surrounding it, and was built after the plan of a spider's web. It had also a tower at each angle, there being sixteen in all without the citadel, and appears to have been in every respect admirably calculated for security and defence; for if any one of the courts were scaled or taken, the soldiers in the gallery above would so annoy the assailants with their arrows and other missile weapons, as to render it impossible for them to retain possession of it. But notwithstanding the strength and importance of this castle, it does not appear to have been the scene of any events of interest in the history of the kingdom, till the reign of Charles I., when it was one of the first besieged by the parliament, and one of the last which abandoned the cause of the king. Since that time it has been gradually

falling into ruin, so that only a few fragments of it now remain.

The manor of Sherborne was very early granted to the see, and continued attached to it, during its successive removals, till the reign of king Henry VIII., who compelled bishop Piers to alienate it to the crown. Queen Elizabeth granted it to sir Walter Raleigh, on whose unjust execution by king James I. it was seized and given to the favourite Carr, notwithstanding the intercession of various distinguished individuals to obtain it for the family of its great, though unfortunate possessor. It afterwards became the property of sir John Digby, whose descendants still continue to enjoy it. The History and Antiquities of the County of Dorset, by John Hutchins, M.A., 2d edition, corrected and improved by Richard Gough, esq. and John Bowyer Nichols, esq. vol. iv. fol. 1815.

SHERBURN, a market-town in a parish of the same name, partly within the liberty of St. Peter of York, and partly in the upper division of the wapentake of Barkiton Ash, West Riding of Yorkshire, England, is situated at the distance of 14 miles S.W. from the city of York, and 181 miles W. by N. from London. The market is held on Friday weekly, but is little frequented, and there is only one annual fair, on the 25th of September. This place was formerly, however, much more important, and was distinguished by a palace belonging to the archbishops of York, of which not a vestige now remains. It is only at present, therefore, remarkable for a particular species of plum called the Winefour, which grows in the vicinity. Sherburn township, according to the parliamentary returns of 1811, contains 188 houses, and 958 inhabitants. Beauties of England and Wales, vol. xvi. by John Bigland, 1812.

SHERBURNE, EDWARD, in *Biography*, an ingenious writer, was born in London in 1618, and educated under Farnaby; after which he went abroad, but returned in 1641, and succeeded, on the death of his father, to the office of clerk of the ordnance. He was imprisoned for some time by the parliament, and, on his recovering his liberty, joined the king, whom he served with fidelity and great bravery, by which he suffered considerably in his estate. After the battle of Edgehill he went to Oxford, where he was created master of arts. At the restoration he recovered his situation under government, was knighted, and made commissary-general of the artillery. He died in 1702. He translated Seneca's tragedies, the Sphere of Marcus Manilius, and other works, into the English language, and was author of a volume of poems.

SHERBURNE, in *Geography*, a post-town of America, in Chenango county, New York; containing 1282 inhabitants.—Also, a town in the state of Massachusetts, and island of Nantucket. The island contains 6807 inhabitants. (See NANTUCKET.)—Also, a town in Middlesex county, Massachusetts, containing 770 inhabitants; 18 miles S.W. of Boston.—Also, a town of Herkemer county, New York; containing, by the census in 1796, 483 inhabitants.—Also, a town of Rutland county, Vermont; containing 116 inhabitants.

SHERBATOF, PRINCE, in *Biography*, a learned Russian nobleman, who published several works in his own language, the chief of which is "The History of Russia from the earliest Times," which is said to be well arranged, and faithfully drawn up. Mr. Coxe, in speaking of this writer, says, several persons have published collections of state-papers and other documents, but the honour of composing a complete history of Russia is probably reserved for prince Sherebatof; who, if we except Mr. Muller, has contributed

contributed more than any other person towards illustrating the Russian annals. This learned nobleman is editor of "A Journal of Peter the Great," in 2 vols. 4to., which he found in the archives, and published by order of the empress; of "The Russian History, by an ancient Annalist, from the Beginning of the Reign of Vladimir Monomacha in 1114 to 1472;" "The Life of Peter the Great," in the Russian language, first published at Venice, which the prince reprinted in 1774, and, according to his usual custom, enriched with many historical observations. Of his History, already referred to, our author says, "I have read the German translation of this performance, which appears to me a most valuable addition to the history of the North. The author has had access to the imperial archives; he draws his information from the most ancient and unquestionable sources, is particularly exact in quoting his authorities, and ranges the events in a chronological series with great perspicuity." Coxe's Travels, vol. iii.

SHERËT, in *Geography*, a town of Asiatic Turkey, in the government of Trebifond; 30 miles S.W. of Trebifond.

SHEREZUR, or SHERZOUR, or *Scherezur*, a town of Curdistan, the capital of a government, and residence of a Turkish pacha; 150 miles N. of Bagdad. N. lat. 35° 46'. E. long. 44° 25'.

SHERIBON. See CHERIBON.

SHERIDAN, THOMAS, in *Biography*, was born probably about the year 1684, in the county of Cavan, where his parents lived in such a state of indigence, as not to be able to afford him the advantages of a liberal education; but being observed to give early indications of genius, he attracted the notice of a friend to his family, who sent him to the college of Dublin, and contributed towards his support, while he remained there. Afterwards he proceeded to a doctor's degree, and took orders, and set up a school in Dublin, which long maintained a very high degree of reputation, as well for the attention bestowed on the morals of the scholars, as for their proficiency in literature. He does not appear to have had any considerable preferment; but his intimacy with Swift procured for him, in 1725, a living in the south of Ireland, worth about 150*l. per annum*, which he went to take possession of; and, by an act of inadvertence, it is said, destroyed all his future expectations of rising in the church: for being at Cork on the 1st of August, the anniversary of the king's birth-day, he preached from the text "Sufficient for the day is the evil thereof." The report of the fact was spread abroad: he was struck out of the list of chaplains to the lord-lieutenant, and forbidden the castle. He afterwards changed his living for that of Dunboyne, which by the knavery of the farmers, and power of the gentlemen in the neighbourhood, fell in value to 80*l. per annum*. He willingly resigned it for the free-school of Cavan, where he might have lived well; but the air being moist, and as he thought unhealthy, and being disgusted with some of his parishioners, he sold the school for about 400*l.*; and having spent the money, he fell into ill health, and died September 10th, 1758, in the 55th year of his age. He is thus characterized by lord Corke: "Dr. Sheridan was a schoolmaster, and in many instances perfectly adapted to that station. He was deeply versed in the Greek and Roman languages, and in their customs and antiquities. He had that kind of good nature, which absence of mind, indolence of body, and carelessness of fortune, produce; and though not over-strict in his own conduct, yet he took care of the morals of his scholars, whom he sent to the university remarkably well grounded in all kinds of classical learning, and not ill instructed in the social duties of life. He was slovenly, indigent, and cheerful.

VOL. XXXII.

He knew books much better than men, but he knew the value of money less of all. In this situation, and with this disposition, Swift fastened upon him as upon a prey, with which he intended to regale himself, whenever his appetite should prompt him." Dr. Sheridan published a profane translation of Perflus, to which he added the best notes of former editors, together with some very judicious ones of his own. He also translated the *Philoctetes* of Sophocles.

SHERIDAN, THOMAS, son of the preceding, was born at Quilca, in the county of Cavan, in Ireland; and he had for his god-father dean Swift. The early part of his education he received from his father, who afterwards sent him to Westminster school, and at a time when he could very ill afford it. Here, upon examination, he attracted notice; and although a mere stranger, he was elected a king's scholar, on account of his merit. But their maintenance sometimes running short, the doctor was so poor that he could not add fourteen pounds, to enable his son to finish the year; which if he had been able to have done, he would have been removed to a higher class, and in another year would have been sent off to a fellowship at college. Being thus recalled to Dublin, he was sent to the university, where he obtained an exhibition, and in 1738 he took his degree of M.A. Having no interest in the church, nor the means of preparing himself for one of the liberal professions, he resolved to seek a support on the stage. He was received with great applause, and in a short time became manager of the Dublin theatre; in which capacity he successfully undertook the curbing of that licentiousness, which had long reigned with an almost unlimited empire behind the scenes, and the putting a stop to the liberties daily taken by the young men with the female actresses. During eight years Mr. Sheridan possessed this important office of manager of the Dublin theatre with all the success, both with respect to fame and fortune, that could well be expected, when an unfortunate circumstance led him to oppose the wishes of the public, which obliged him to withdraw from the management of the theatre, and even to quit the country. He continued in England till the year 1756, when he returned to Dublin, and was again received on the stage with the highest applause; but he did not continue long in that situation, being opposed and ruined by rival actors.

In 1757 he published a plan, in which he proposed to the Irish the establishment of an academy, for the accomplishment of youth in every qualification necessary for a gentleman. In the formation of this design he included oratory, as one of the essentials; and in order to give a stronger idea of the utility of that art, he opened his plan to the public in some orations, which were so well written, and so admirably delivered, as to give the highest proofs of the ability of the proposer, and his fitness for the office of superintendent of such an institution, for which post he had offered himself. Nevertheless, though the plan was, in a measure, carried into execution, Mr. Sheridan was excluded from any share in the conduct of it. He now came again to England, and delivered lectures on elocution and oratory in the theatres of Oxford and Cambridge, to very numerous audiences, and with the highest reputation. From thence he again came to London, where he was engaged as an actor and a lecturer. In 1778 he published "A pronouncing Dictionary of the English Language;" and after this he became a manager of the Drury-lane theatre, under his son, the present Mr. Sheridan, who was then one of the patentees. He died in August, 1788. His works are as follow: 1. "A Dictionary of the English Language." 2. "Lectures on the Art of Reading." 3. "British Education, or the Source of the Disorders of Great Britain." 4. "A Dissertation on the Causes of the Difficulties

which occur in learning the English Tongue." 5. "A Course of Lectures on Elocution." 6. "The Life of Swift," prefixed to an edition of his works, edited by Mr. Sheridan. 7. "Elements of English." His wife Frances, whose maiden name was Chamberlaine, was a very ingenious woman, and was author of a novel, entitled "Sidney Biddulph;" a moral romance, entitled "Nourjahad;" "The Discovery," a comedy; and another, entitled "The Dupe." She died at Blois, in 1767.

SHERIDAN, the late *Mrs.*, was daughter of the excellent musician, Mr. Linley, so well known at Bath, by his professional merit as a master, by the beauty and talents of his family, and by his vocal compositions, particularly his Elegies. If this were a place to celebrate the beauty and fascinating manners of Mrs. Sheridan, we could dwell upon them as long as on her voice and musical talents; but to these we must confine ourselves. There was a brilliancy, a spirit, and a mellifluous sweetness in the tone of her voice, which instantly penetrated the hearts of her hearers, as much as her angelic looks delighted their eyes. Her shake was perfect, her intonation truth itself, and the agility of her throat equal to any difficulty and rapidity that was pleasing. But in Handel's pathetic songs, in Purcell's "Mad Bells," in the upper part of serious glees, or whatever vocal music had impassioned words to express, she was sure to make them felt by every hearer possessed of intelligence and sensibility.

She knew music so well, that she was sure to do justice to every kind of Italian composition, as much as a foreigner ever did to a language not her own; though the energy and accent given by the natives of Italy, particularly in recitative, is ever comparatively deficient in the best singers of all other countries; as nothing but a long residence, early in life, in a foreign country, can acquire the correct pronunciation of its music, any more than of its language. It was observed by Sacchini, who heard Miss Linley sing at Oxford for the last time, that if she had happened to have been born in Italy, she would have been as much superior to all Italian singers, as she was then to those of her own country.

SHERIF, in the *Egyptian Orders*, the relations of Mahomet, the same tribe of persons called emir by the Turks.

The word is Persian, and signifies *great* or *noble*; and these persons have the privilege of being exempt from appearing before any judge but their own head; and if any of the military orders are obliged to punish them for any misdemeanor, they first take off their green turban, in respect to their character; and the same is done even when they are punished by their own magistrate.

The sheriff, sherriffe, or seherif of Mecca, is the title of the descendants of Mahomet by Hassan ibn Ali. Although this branch of the posterity of Mahomet has never attained to the dignities of calph or imam, it appears to have always enjoyed the sovereignty over most of the cities in the Arabian province of Hedsjas. The family of Ali-Bunemi, being one branch of the descendants of Hassan ibn Ali, and consisting of at least 300 individuals, enjoys the sole right to the throne of Mecca. This family is likewise subdivided into two subordinate branches, of which sometimes the one, sometimes the other, has given sovereigns to Mecca and Medina, when these were separate states; but the Turkish sultan is indifferent about the order of succession in the family, rather wishing to favour the strongest, that he may weaken them all. As the order of succession is not absolutely fixed, and the sherriffes may all aspire alike to the sovereign power, this uncertainty of right, aided by the intrigues of the Turkish officers, occasion frequent revolu-

tions. The grand sherriffe is seldom able to maintain himself on the throne; and it still seldomer happens, that his reign is not disturbed by the revolt of his nearest relations. The dominions of the sherriffe comprehend the cities of Mecca, Medina, Jambo, Taaf, Sadie, Ghunfude, Hali, and thirteen other less considerable, all situated in Hedsjas. As these dominions are neither extensive nor opulent, the revenue of their sovereign cannot be considerable. He finds a rich resource, however, in the imposts levied on pilgrims, and in the gratuities offered him by Mussulman monarchs. Every pilgrim pays a tax of from 10 to 100 crowns, in proportion to his ability. The Grand Mogul remits annually 60,000 rupees to the sherriffe, by an assignment on the government of Surat; but since the English have made themselves masters of this city, and the territory belonging to it, the nabob of Surat has no longer been able to pay the sum. The power of the sherriffe extends not to spiritual matters: these are entirely managed by the heads of the clergy of different sects, who are resident at Mecca. Rigid Mussulmans, such as the Turks, are not very favourable in their sentiments of the sherriffes, but suspect their orthodoxy, and look upon them as tacitly attached to the tolerant sect of the Zeidi. See SCHERIF.

SHERIFF, or SHIRE-REVE, an officer in each county of England, of very great antiquity; his name being derived from the two Saxon words *scire*, province or shire; or rather from *sciran*, to divide, and *gerefa*, grave, reve, or presēt; the sheriff being denominated from the first division of the kingdom into counties.

He is called in Latin *vice-comes*, as being the deputy of the earl or comes, to whom the custody of the shire is said to have been committed at the first division of this kingdom into counties: but the earls being afterwards unable, by reason of their high employments, and attendance on the king's person, to transact the business of the county, the labour was committed to the sheriff; who now performs all the king's business in the county; and though he be still called *vice-comes*, yet he is entirely independent of, and not subject to, the earl: the king, by his letters patent, committing *custodiam comitatus* to the sheriff.

Sheriffs were formerly chosen by the inhabitants of the several counties; in confirmation of which, it was ordained by 28 Edw. I. c. 8. that the people should have election of sheriffs in every shire, where the sheriffalty is not of inheritance; for anciently in some counties the sheriffs were hereditary, as judge Blackstone apprehends they were in Scotland, till the statute 20 Geo. II. c. 43. and still continue in the county of Westmoreland to this day: the city of London having also the inheritance of the sheriffalty of Middlesex vested in their body by charter. This election, says the same author, was, in all probability, not absolutely vested in the commons, but required the royal approbation. For in the Gothic constitution, the judges of their county-courts (which office is executed by our sheriff) were elected by the people, but confirmed by the king; and the form of their election was thus managed: the people, or *incolæ territorii*, chose twelve electors, and they nominated three persons, *ex quibus rex unum confirmabat*. But with us in England, these popular elections growing tumultuous, were put an end to by the statute 9 Edw. II. st. 2. which enacted, that the sheriffs should from thenceforth be assigned by the chancellor, treasurer, and the judges, as being persons in whom the same trust might with confidence be reposed. By statutes 14 Edw. III. c. 7, 23 Hen. VI. c. 8, and 21 Hen. VIII. c. 20, the chancellor, treasurer, president of the king's council, chief justices, and chief baron, are to make this election on the morrow of All-Souls in the exchequer: and the king's letters patent, appointing the new sheriffs,

used commonly to bear date the sixth day of November. 12 Edw. IV. c. 1.

And the custom now is, which has obtained since the time of Henry VI. that all the judges, together with the other great officers, meet in the exchequer chamber on the morrow of All-Souls yearly (which day is now altered to the morrow of St. Martin, by the last act for abbreviating Michaelmas term), and then and there propose three persons to the king, who afterwards appoints one of them to be sheriff.

This custom of the twelve judges proposing three persons, seems borrowed from the Gothic constitution before-mentioned; with this difference, that among the Goths the twelve nominees were first elected by the people themselves: which usage of our's was probably founded upon some statute, though not now to be found among our printed laws. But notwithstanding an unanimous resolution of all the judges of England to this purpose, entered in the council-book of 3 March, 34 Hen. VI. and the statute 34 & 35 Hen. VIII. cap. 26. sect. 61. which expressly recognizes this to be the law of the land; some of our writers have affirmed, that the king, by his prerogative, may name whom he pleases to be sheriff, whether chosen by the judges or not. This is grounded on a very particular case in the fifth year of queen Elizabeth, when, by reason of the plague, there was no Michaelmas term kept at Westminster, so that the judges could not meet there in *crasino animarum*, to nominate the sheriffs; upon which the queen named them herself, without such previous assembly, appointing for the most part one of the two remaining in the last year's list. And this case, so circumstanced, is the only authority in our books for making these extraordinary sheriffs.

However, it must be acknowledged, that the practice of occasionally naming what are called pocket-sheriffs, by the sole authority of the crown, hath uniformly continued to the reign of his present majesty, George III. in which, says Blackstone, few, if any, instances have occurred.

By four several statutes it is enacted, that no one shall be sheriff, except he have sufficient land within the shire to answer the king and the people in any manner of complaint. 9 Edw. II. st. 2. 4 Edw. III. c. 9. 5 Edw. III. c. 4. 13 & 14 Car. II. c. 21.

It has been judged, that an attorney is exempted from the office of sheriff, by reason of his attendance on the courts of Westminster.

By 2 Geo. III. c. 20. no person, during the time he is acting as a militia-officer, shall be obliged to serve the office of sheriff.

Protestant dissenters, who are exempted by the Toleration act from the obligation of complying with the requisition of the Corporation act, and who can plead their non-compliance as a reasonable and sufficient excuse, are not compellable to serve this office, nor of course to pay any fine for refusal. See Furneaux's Letters to Blackstone, ed. 2, and particularly the Appendix, containing lord Mansfield's speech in the house of Lords 1767, on the cause between the city of London and the dissenters, when the house affirmed the unanimous judgment of the commissioners' delegates, who delivered their opinions *seriatim* on the 5th of July, 1762, after hearing counsel several days.

By a by-law of the city of London, passed in a common-council June 11th, 1799, amending an act of April the 7th, 1748, no freeman chosen sheriff, &c. shall be excused, unless he voluntarily swears he is not worth 20,000*l.* &c. which oath shall be attested by the oaths of six other freemen; and if he refuses to take the office, he incurs a forfeiture of 400*l.* and twenty marks towards the maintenance of the ministers of the several prisons within the city, together with the usual fines. If, however, he shall afterwards take upon

him the office of an alderman of the city, he shall be eligible to the said office of sheriffalty, notwithstanding the fore-mentioned payment.

The sheriff, before he exercises any part of his office, and before his patent is made out, is to give security in the king's remembrancer's office in the exchequer, under penalty of 100*l.*, for the payment of his proffers, and all other profits of the sheriffwick; he must also take the oaths of allegiance and abjuration, and all, except the sheriffs of Wales and Chester, an oath appointed by 3 Geo. I. cap. 15. sect. 18. for the due execution of their office. This oath may be administered in pursuance of a writ of *dedimus potestatem*.

Sheriffs, by virtue of several old statutes, are to continue in their office no longer than one year; and yet it hath been said, that a sheriff may be appointed *durante bene placito*, or during the king's pleasure, and so is the form of the royal writ; therefore, till a new sheriff be named, his office cannot be determined, unless by his own death, or the demise of the king.

And by 1 Ann. st. 1. c. 8. all officers appointed by the preceding king may hold their offices for six months after the king's demise, unless sooner displaced by the successor.

We may farther observe, that by 1 Rich. II. c. 11. no man, that has served the office of sheriff for one year, can be compelled to serve the same again within three years after.

The power and duty of a sheriff are those that belong to him as a judge, as a keeper of the king's peace, as a ministerial officer of the superior courts of justice, or as the king's bailiff.

In his judicial capacity he is to hear and determine all causes of forty shillings value and under, in his county-court; and he has also a judicial power in divers other civil cases. He is likewise to decide the elections of knights of the shire (subject to the controul of the house of commons), of coroners, and of verderors; to judge of the qualification of voters; and to return such as he shall determine to be duly elected, but incapable of being elected himself for the county, &c. of which he is returning officer.

As the keeper of the king's peace, both by common law and special commission, he is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend and commit to prison all persons who break the peace, or attempt to break it; and may bind any one in a recognizance to keep the peace. He may, and is bound, *ex officio*, to pursue and take all traitors, murderers, felons, and other misdoers, and commit them to gaol for safe custody. He is also to defend his county against any of the king's enemies when they come into the land; and, for this purpose, as well as for keeping the peace and pursuing felons, he may raise the *posse comitatus*.

However, by the express directions of the great charter, the sheriff, together with the constable, coroner, and certain other officers of the king, are forbidden to hold any pleas of the crown, or, in other words, to try any criminal offence; for it would be highly unbecoming, that the executors of justice should be also the judges; should impose as well as levy fines and amercements; should one day condemn a man to death, and personally execute him the next.

Neither may he act as an ordinary justice of the peace during the time of his office, for this would be equally inconsistent, he being in many respects the servant of the justices.

In his ministerial capacity, the sheriff is bound to execute all process issuing from the king's courts of justice. In the commencement of civil causes, he is to serve the writ, to arrest, and to take bail: when the cause comes to trial, he must

must summon, and return the jury; when it is determined, he must see the judgment of the court carried into execution. In criminal matters, he also arrests and imprisons; he returns the jury; he has the custody of the delinquent; and he executes the sentence of the court, though it extend to death itself.

As the king's bailiff, it is the sheriff's business to preserve the rights of the king within his bailiwick; for so his county is frequently called in the writs. He must seize, to the king's use, all lands devolved to the crown by attainder or escheat; must levy all fines and forfeitures; must seize and keep all waifs, wrecks, estrays, and the like, unless they be granted to some subject; and must also collect the king's rents within his bailiwick, if commanded by process from the exchequer.

To execute these various offices, the sheriff has under him many inferior officers, an under-sheriff, bailiffs, and gaolers, who must neither buy, sell, nor farm their offices, on forfeiture of 50*l.* 3 Geo. I. c. 15.

The under-sheriff usually performs all the duties of office, few excepted, with regard to which the personal presence of the high sheriff is necessary. But no under-sheriff shall abide in his office above one year by 42 Edw. III. c. 9. and if he does, by 23 Hen. VI. c. 8. he forfeits 200*l.*; and no under-sheriff, or sheriff's officer, shall practise as an attorney during the time he continues in such office, by 1 Hen. V. c. 4. But these regulations are evaded, by practising in the names of other attorneys, and putting in them deputies by way of nominal under-sheriffs.

The under-sheriff, before he enters upon his office, is to be sworn, by 27 Eliz. c. 12. And by 3 Geo. I. c. 15. sect. 19. it is enacted, that all under-sheriffs of any counties in South Britain, except the counties in Wales, and the county palatine of Chester, shall take an oath for the due execution of their office. Blackit. Com. b. i.

**SHERIFF'S COURT.** See *COUNTY COURT*, and *MAYOR'S COURTS*.

**SHERIFF'S Tourn, or Turn.** See *TURN*.

**SHERIFF, Apposal of.** See *APPASAL*.

**SHERIFFS, Issues on.** See *ISSUES*.

**SHERIFF, in Commerce.** See *XERIFF*.

**SHERIL**, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir, on the Euphrates; 20 miles E. of Anah.

**SHERILLA**, a town of Africa, in Kaarta. N. lat. 14° 29'. W. long. 6° 25'.

**SHERLING, or SHIRLING Lambs**, in *Rural Economy*, the practice of cutting or shearing the short woolly coats or coverings of these young animals in the summer season, about the time at which the old sheep are clipped. Both the term and the custom are common in the northern districts, though they are scarcely known in the more southern parts of the island. Probably the greatest part of the lambs which are brought to Smithfield market, as well as of those which are bought by the butchers of the metropolis, are never *shered* or freed from their coats, by which a very great individual as well as national loss is sustained. Perhaps the lambs are more saleable when kept in their full coats. The practice is, however, worthy of being more attended to in all situations.

The clipping or shirling of the lambs in some districts has, however, been considered as injurious, by the operation's hurting the growth of them; though no such effect has been discovered to take place in the South Down sheep tract of the county of Suffex, or those of many other parts of the north. The profit in the above district is, however, thought to be trifling, or such as only to repay the expences, and a little more; but it has a tendency to improve

the wool, and cause it to throw out a more luxuriant staple. See *WOOL*.

**SHERLOCK, WILLIAM**, in *Biography*, an eminent divine in the English church, was born in London in 1641. He was educated at Eton, and thence he went to Peter-House, Cambridge, where he applied himself with much assiduity to his studies, obtained a good reputation, took orders, and officiated as a curate till the year 1669, when he was presented to the rectory of St. George's, Botolph Lane, London. He stood high in character among the London clergy, when he published "A Discourse concerning the Knowledge of Christ, and our Communion with Him," being intended as a confutation of the Antinomian doctrine, which brought upon him several antagonists, against whom he vindicated himself with judgment and zeal. In 1680 he took the degree of D.D. and in the following year he obtained a prebend in the cathedral of St. Paul's. The discovery of what was called the Rye-house plot, having called forth the spirit of loyalty, Dr. Sherlock appeared as an assertor of the doctrine of non-resistance, in a work entitled "The Case of Resistance to the supreme Powers stated and resolved according to the Doctrines of the Holy Scriptures." In this piece he maintained that the authority of the sovereign was in his *person*, and not in the *law*:—that he does not receive his authority from the laws, but that the laws receive their power from him;—and that it does not become a man who can reason at all to talk of the authority of the laws in derogation to the authority of the sovereign power. From these slavish principles he did not in the least swerve, even after the accession of James II. had still more endangered the public liberties and religion of the country. His notion of passive obedience did not, however, prevent him from opposing Popery, for he was among the first who, in those times, engaged in controversy with the Papists, in which he wrote a great number of tracts.

After the revolution, Dr. Sherlock for some time remained firm in his high monarchical principles; and refusing to take the oaths to the new government, was suspended from all his preferments, among which was the mastership of the Temple. It was during this suspension from his labours as a preacher, that he published the treatise on "Death," to which he is chiefly indebted for celebrity as an author. It was entitled "A Practical Discourse concerning Death," and few works have been more popular among all classes. It went through thirty editions in a short space of time, has been printed in all sizes and forms, and has been applauded by the most able critics.

Not long after the publication of this work, Dr. Sherlock's scruples with respect to government gave way; he took the oaths, and was reinstated in all his preferments. This step of course exposed him to the censure of the party with whom he had long acted, and to vindicate himself he published a piece, entitled "The Case of the Allegiance due to sovereign Powers stated and resolved." In 1692 he published his "Vindication of the Doctrine of the Holy and Ever-blessed Trinity." In this he maintained that there were three eternal minds, which exposed him to the charge of tritheism; it did not, however, prevent his promotion to the deanery of St. Paul's, on the recommendation of Dr. Tillotson, who was raised to the archbishopric of Canterbury.

This rise in the church exasperated still more those who were already indisposed against him for his desertion of his former principles, and Dr. South published in 1693, "Animadversions upon Dr. Sherlock's Book, &c." An eager controversy followed, in which the university of Oxford took part, by censuring in a public decree the hypothesis of Dr. Sherlock, as maintained by a preacher at that place. The contest being carried on with great acrimony, the king, at the

the desire of the bishops, interposed with a prohibition of the use of new terms in the explication of the doctrine of the Trinity.

In 1704 Dr. Sherlock published "A Discourse on the Immortality of the Soul," in which he made an attack on Locke's opinion concerning innate ideas. He died in 1707, in the 67th year of his age. After his decease, his sermons, which had been printed during his life, were collected, and with others printed in two volumes, 8vo.

SHERLOCK, THOMAS, a distinguished prelate, and son of the preceding, was born in London in 1678. He received his classical education at Eton, and from thence he removed to Catharine-hall, Cambridge, about the year 1693. In process of time he became a fellow of that society, entered into holy orders, and upon the resignation of his father in 1704, he succeeded to the office of master of the Temple. In the duties of this office he exerted himself with so much success, that few English divines have acquired so high a reputation for pulpit oratory, in the qualities of strength and solidity of reasoning, and forcible and manly eloquence.

He commenced doctor of divinity in 1707, and in 1714 was elected master of Catharine-hall. Being promoted to the deanery of Chichester in 1726, he soon after made his first appearance in print, as a champion of the establishment, in "A Vindication of the Corporation and Test Acts, in answer to the Bishop of Bangor's Reasons for the Repeal of them." This was replied to by the worthy prelate, and supported in a rejoinder by the dean.

Dr. Sherlock's next work was entitled "The Use and Intent of Prophecy in the several Ages of the World," which was the substance of some sermons preached in the Temple church, occasioned by the controversy between Collins and several divines on the subject of prophecy. In 1728 he was promoted to the see of Bangor, in which he succeeded his antagonist Hoadly, as he did, in 1738, in that of Salisbury. As a member of the upper house, he took an active part in its debates, and was always a supporter of the interests of the crown and the church. He was considered, in parliament, as a great authority in ecclesiastical law, and frequently led the judgment of the house; and such at length was the reputation which he had in the episcopal character, that upon the death of archbishop Potter, in 1747, he was offered to succeed him in the see of Canterbury, which he declined on account of ill health, but afterwards recovering, he accepted the see of London in 1749. In 1753 he resigned the mastership of the Temple, and was very soon after incapacitated for any very active service: he nearly lost the use of his limbs and speech, but still retained the vigour of his understanding, and was capable of revising and correcting a volume of sermons: this was followed by four others, which are in high estimation. The bishop died in 1761, in the 84th year of his age.

SHERMA, or CHERMA, in *Geography*, a province of the kingdom of Morocco, which lies between the province of Hea and that of Morocco, and has been dismembered from that of Hea. See SHEDMA.

SHERMAN, a town of America, in the state of Connecticut and county of Fairfield, containing 949 inhabitants.

SHERMANSLI, a town of Asiatic Turkey, in Natolia; 48 miles W. of Bursa.

SHERONA, a town of Egypt, on the right bank of the Nile; 8 miles N. of Abu Girgê.

SHERRINGHAM, in *Biography*, a composer of songs in parts during the reign of Henry VII. which have been preserved with those of other contemporary composers in the Fairfax MS. the most ancient book of the kind that we have ever been able to discover. See FAIRFAX.

SHERSHELL, in *Geography*, a town of Africa, in the kingdom of Algiers, generally supposed to be the city called *Jol*, and by the younger Juba named *Casarea*, in compliment to Augustus. This town, when Dr. Shaw saw it, in the year 1730, was in great reputation for making steel, earthen vessels, and such iron tools as are wanted in the neighbourhood: but a few years afterwards (1738) it was entirely thrown down by an earthquake. The ruins upon which this town was situated, are not inferior in extent to those of Carthage; and we may likewise conceive no small opinion of its former magnificence, from the fine pillars, capitals, spacious cisterns, and beautiful Mosaic pavements, that are every where remaining. They have a tradition, that the ancient city was destroyed, as the new one was lately, by an earthquake; and that the port, formerly very large and commodious, was destroyed by the shock, and other adjacent buildings being thrown into it by the shock. The cothon, or artificial harbour, that had a communication with the western part of the port, is the best proof of this tradition: for when the sea is calm, and the water low, (as frequently happens after strong south or east winds,) all over the area of it so many masonry pillars and pieces of great walls may be seen, that it cannot well be conceived how they should come there without such a concussion. The port is nearly of a circular form, of 200 yards in diameter; but the securest part of it, which, till of late was towards the cothon, is now filled up with a bank of sand, that daily increases. However, there still lies in the mouth of it a small rocky island, which at present is the main shelter and defence against the northern tempest. N. lat. 36° 35'. E. long. 2° 30'.

SHERVEND, a town of Persia, in the province of Irak; 32 miles N. of Confar.

SHERWOOD FOREST. See SHIREWOOD *Forest*.

SHERZOUR. See SHEREZUR.

SHESBEQUIN, a post-town of America, in Luzerne county, Pennsylvania; 80 miles N.N.W. of Philadelphia.

SHESHME-BAND, a town of Persia, in the province of Segellan; 50 miles W.S.W. of Ferah.

SHESHMESHA, a town of Persia, in the province of Khoratan; 35 miles W. of Tabas-Kuleki.

SHETABAVA, a town of Hindoostan, in the Carnatic; 40 miles S. of Tanjore.

SHETERU, a town of Hindoostan, in Coimbatore; 5 miles N.W. of Erroad.

SHETLAND ISLANDS. See ZETLAND *Islands*.

SHERLAND *Sheep*, in *Agriculture*, a breed of fine-woolled sheep peculiar to the Shetland islands. See SHURP.

SHEPUCKET, in *Geography*, a river of America, in Connecticut, formed by the junction of Willomantic and Mount Hope rivers, which after running E. a few miles pursues a southern course, and uniting with Quinnabang river discharges itself into the Thames in the southern part of the township of Norwich.

SHEVADY, a town of Hindoostan; 8 miles W.N.W. of Pullumware.

SHEVAGUNGA, a town of Hindoostan, in Myfore; 25 miles N.W. of Bangalore. N. lat. 13° 6'. E. long. 77° 13'.

SHEVAGURY, a town of Hindoostan, in Madura; 15 miles N.W. of Colpetta.

SHEVALORE, a town of Hindoostan, in Marawar; 8 miles N.W. of Trumian.

SHEVALPETTORE, a town of Hindoostan, in Marawar; 32 miles N.N.W. of Ramnadporum.—Also, a town of Hindoostan, in the province of Madura; 35 miles S.S.W. of Madura.

SHEVA-

**SHEVAPORUM**, a town of Hindoostan, in the country of the Nays; 15 miles E. of Tellicherry.

**SHEVGUNGA**, a town of Hindoostan, in Marawar; 20 miles S. of Tripattore.

**SHEVITON INDIANS**, Indians of North America. N. lat. 47° 30'. W. long. 104° 45'.

**SHEW-BOX** for Prints. See **CAMERA**.

**SHEWAGE**. See **SCAVAGE**.

**SHEW-BREAD**, in the *Jewish Economy*. The Hebrew (Exod. xxv. 30.) לֶחֶם פָּנִים, לֶחֶם פָּנִים, signifies literally "bread of faces, or of the faces." This denomination was given to the loaves of bread, which the priest of the week placed every Sabbath-day on the golden table in the sanctuary, before the Lord. These loaves were of a square form, with four faces, as the rabbins say, and were twelve in number, representing the twelve tribes of Israel. They supplied the place of those which had been exposed the whole week, and none could lawfully eat them but the priests. This offering was accompanied with frankincense and salt. Of the first fruits and tenths presented by the Israelites to the priests, the latter took that which was necessary for making the shew-bread, and for supplying the service of the temple with any thing else which it was their duty to furnish.

**SHEWIN**, or **SEWIN**, in *Ichthyology*. See **GREY**.

**SHGIGATCHEE**, in *Geography*. See **SGIGATCHEE**.

**SHIAB**, a town of Arabia, in the province of Hedjas; 84 miles S.E. of Calaat al Moilah.

**SHIANDAMANGALY**, a town of Hindoostan, in the province of Tinevelly; 10 miles S. of Tutacoron.

**SHIANSHIA**, a town of Egypt; 25 miles S. of Manfara.

**SHIANT ISLANDS**. See **SHIAINT**.

**SHIBBOLETH**, or **SIBBOLETH**, a Hebrew word which signified spica, or an ear of corn. It was used by way of distinguishing the Ephraimites from the men of Gilead. For the latter having killed a great number of the former, set guards at all the passes of Jordan; and when an Ephraimite, who had escaped, came to the water-side, and desired to pass over, they asked him if he was not an Ephraimite? If he said no, they bade him pronounce Shibboleth. But he pronouncing it Sibboleth, according to the manner of the Ephraimites, and thus not enunciating the first letter, was killed on the spot: on this occasion, 42,000 Ephraimites were killed. By thus not distinguishing between the ש and the ס, the schin and the sin, they exposed themselves to this massacre: hence the terms have been used to denote the trivial grounds on which contending parties, particularly in theological disputes, often differ, and proceed to think ill of, and actually to persecute, one another.

**SHIBKAH**, in *Geography*, an extensive salt-plain of Algiers, overflowed in winter, but dry in summer; 10 miles S. of Oran.

**SHICARAN**, a town of Asiatic Turkey, in the province of Diarbekir; 18 miles W.S.W. of Hazou.

**SHIDES**. See **SHINGLES**.

**SHIEL**, **LOCH**, in *Geography*, a lake in the parish of Ardnamurchan, and county of Inverness, Scotland; extending ten miles in length, and two in breadth. Near its centre rises an islet, called Island Fiman, which contains the ruins of a chapel dedicated to the faint of that name. This lake discharges its waters into the Western ocean at Cattle Tioram, by the river Shiel. Statistical Account of Scotland, by Sir John Sinclair, vol. ii. 1792.

**SHIELD**, an ancient weapon of defence, in form of a light buckler, borne on the arm to fend off lances, darts, &c.

The form of the shield is represented by the escutcheon in coats of arms.

The shield was that part of the ancient armour on which the persons of distinction in the field of battle always had their arms painted; and most of the words used at this time to express the space that holds the arms of families, are derived from the Latin name for a shield, *scutum*. The French *escu*, and *escussion*, and the English word, *escutcheon*, or, as we commonly speak it, *scutcheon*, is evidently from this origin; and the Italian *scudo* signifies both the shield of arms, and that used in war.

The Latin name *clypeus*, for the same thing, seems also to be derived from the Greek word *κλυπεω*, *to engrave*; and it had this name from the several figures engraved on it, as marks of distinction of the person who wore it.

The shield in war, among the Greeks and Romans, was not only useful in the defence of the body, but it was also a token or badge of honour to the wearer, and he who returned from battle without it, was always treated with infamy afterwards.

People have at all times thought this honourable piece of the armour the properest place to engrave or figure on the signs of dignity of the possessor of it; and hence, when arms came to be painted for families in after-times, the heralds always chose to represent them upon the figure of a shield, but with several exterior additions and ornaments, as the helmet, supporters, and the rest.

The form of the shield has not only been found different in various nations, but even the people of the same nation, at different times, have varied its form extremely; and among several people there have been shields of several forms and sizes in use, at the same period of time, and suited to different occasions.

The most ancient and universal form of shields, in the earlier ages, seems to have been the triangular, vulgarly called the heater shield, from its resemblance to that instrument of housewifery. This we see instances of in all the monuments and gems of antiquity: our own most early monuments shew it to have been the most antique shape also with us, and the heralds have found it the most convenient for their purposes, when they had any odd number of figures to represent; as if three, then two in the broad bottom part, and one in the narrow upper end, it held them very well; or if five, they stood as conveniently, as three below, and two above. Most of the monumental figures of cross-legged knights are armed with triangular shields, which are generally a little convex, or curved in their breadth; their upper extremity terminated by a line parallel to the horizon, and their sides formed by the intersection of the segments of two circles. Such are generally represented on ancient seals and windows: sometimes, though not often, their surfaces are flat. On the inside of the Norman shields were two or more loops of leather, or wooden handles, through which the arm and hand were passed, when the shield was braced, and prepared for use; at other times it was carried by a leathern thong worn round the neck. The other form of a shield, now universally used, is square, rounded, and pointed at the bottom: this is taken from the figure of the Samnitic shield used by the Romans, and since copied very generally by the English, French, and Germans. See **TARGET**.

The shield, though it was not entirely relinquished so long as the use of the long and cross bows continued, seems to have undergone some alteration in its form; the triangular, or heater shield, gradually giving place to those of a circular or rectangular figure. Shields were first left off by the cavalry; they were, however, used in the army of king Edward I., at the siege of Karlaverok, in the year 1300.

A fort

A sort of shields was worn by the Scots at the battle of Musselborough, in the first year of Edward VI. Shields or bucklers seem to have been used in affrays and private quarrels, by persons in the civil line, as late as the reigns of Elizabeth and king James I. The common appellation for a quarrelling or fighting fellow about that period was a swash-buckler, that is, a breaker or clasher of bucklers. Maurice, prince of Orange, was a great advocate for the shield, and even attempted to revive the use of it. His company of Dutch guards was armed with targets and roundels, and he formed a regular plan of exercise for them. The target and broad sword were the favourite arms of the Scotch Highlanders as late as the year 1746, and even after. Swords and bucklers were anciently borne before great military officers, as insignia of their dignity: those carried before king Edward III. in France, are shewn in Westminster Abbey. The shield borne before the commandant of the forces on board the Spanish Armada, is preserved in the Tower, and a sword was borne before the bishop of Norwich, as commander of the troops with which he intended to serve king Richard II. Most of the ornamented metal shields, and many of the very large swords, were designed for this use.

The Spaniards and Portuguese have the like general form of shields, but they are round at the bottom, without the point; and the Germans, beside the Samnite shield, have two others pretty much in use: these are, 1. The bulging shield, distinguished by its swelling or bulging out at the flanks; and, 2. The indented shield, or shield chancree, which has a number of notches and indentings all round its sides. The use of the ancient shield of this form was, that the notches served to rest the lance upon, that it might be firm while it gave the thrust; but this form being less proper for the receiving armorial figures, the two former have been much more used in the heraldry of that nation.

Another form of shield derived its name roundel, or rondacha, from its circular figure; it was made of osiers, boards of light wood, sinews or ropes, covered with leather, plates of metal, or stuck full of nails, in concentric circles, or other figures. The shields and roundels of metal, particularly those richly engraved or embossed, seem rather to have been insignia of dignity, anciently borne before generals or great officers, than calculated for war; most of them being either too heavy for convenient use, or too slight to resist the violence of a stroke either from a sword or battle-axe. Although most roundels are convex, we meet with many that are concave; but these have commonly an umbo. The handles are placed as in the shield and target. The roundel seems, in many instances, to resemble the Roman parma. For another form of shield, see PAVAIS.

Besides this different form of the shields in heraldry, we find them also often distinguished by their different positions, some of them standing erect, and others standing various ways, and in different degrees; this the heralds express by the word *pendant*, *hanging*, they seeming to be hung up, not by the centre, but by the right or left corner. The French call these *ecu pendant*, and the common antique triangular ones *ecu ancien*. The Italians call this *scuto pendente*; and the reason given for exhibiting the shield in these figures in heraldry is, that in the ancient tilts and tournaments, they who were to fight at these military exercises, were obliged to hang up their shields, with their armories or coats of arms on them, out at the windows and balconies of the houses near the place; or upon trees, pavilions, or the barriers of the ground, if the exercise was to be performed in the field. Those who were to fight on foot, according to Columbiere, had their shields hung up by the right corner, and those who were to fight on horse-back, had theirs hung up by the left.

This position of the shields in heraldry is called *couche* by some writers, though by the generality *pendant*.

It was very frequent in all parts of Europe, in arms given between the eleventh and fourteenth centuries; but it is to be observed, that the hanging by the left corner, as it was the token of the owner's being to fight on horse-back, so it was esteemed the most honourable and noble situation; and all the pendant shields of the sons of the royal family of Scotland and England, and of our nobility, at that time, are thus hanging from the left corner. The hanging from this corner was a token of the owner's being of noble birth, and having fought in the tournaments before; but no sovereign ever had a shield pendant any way, but always erect, as they never formally entered the lists of the tournament.

The Italians generally have their shields of arms of an oval form; this seems to be done in imitation of those of the popes, and other dignified clergy; but their herald, Petro Sancto, seems to regret the use of this figure of the shield, as an innovation brought in by the painters and engravers, as most convenient for holding the figures, but derogatory to the honour of the possessor, as not representing either antiquity, or honours won in war, but rather the honours of some citizen, or person of learning. Some have carried it so far, as to say that those, who either have no ancient title to nobility, or have sullied it by any unworthy action, cannot any longer wear their arms in shields properly figured, but were obliged to have them painted in an oval or round shield.

In Flanders, where this author lived, the round and oval shields are in the disrepute he speaks of; but in Italy, besides the popes and dignified prelates, many of the first families of the laity have them.

The secular princes, in many other countries, also retain this form of the shield, as the most ancient, and truly expressive of the Roman clypeus. Nisbet's Heraldry, p. 12. Comonille, Herald.

**SHIELD**, in *Heraldry*, denotes the escutcheon, or field whereon the bearings of the armoury are placed. See ESCUTCHEON.

**SHIELDRAKE**. See TADORNA.

**SHIELDS, WILLIAM**, in *Biography*. Though this musical professor, for the happiness of his acquaintance, still ranks with the living, and we can tell our contemporaries nothing concerning his worth and talents which is not already well known, yet as his name has penetrated into Germany, and has furnished an article in Gerber's Continuation of Walther's Musical Lexicon, we cannot resist confirming the account given of his compositions in that work.

**SHIELDS, North**, in *Geography*, a market-town and feaport in Castle ward, county of Northumberland, England, is situated near the entrance of the river Tyne, on its northern bank, at the distance of half a mile W.S.W. from the town of Tynemouth, and 279 miles N. by W. from London. This town is indebted for its origin to the monks of Tynemouth priory, who erected a number of houses here, and encouraged the settlement of ship-owners and tradesmen, early in the reign of Edward I. They at the same time formed a harbour here for lading and unlading of ships, and established a weekly market and fairs; but the exercise of these privileges having been disputed by the corporation of Newcastle, they were inhibited by a decret of the itinerant judges. From that period it continued to be a mere fishing village till the middle of the seventeenth century, when new efforts were made to render it an important sea-port, for which purpose its situation is admirably adapted. Cromwell, who then held the reins of government, with the consent of parliament

parliament passed an act, in which it was ordered, "that sufficient and well-fenced ballast-shores, quays, and steaths, be built at Shields," and "that North Shields be made a market-town two days in the week, for the relief of the country and garrison of Tynemouth, and for all the great confluence of people and fleets of ships."

In consequence of this act, North Shields would soon have become a place of great commercial importance; but on the restoration, the rights claimed by the corporation of Newcastle were resumed; and North Shields was deprived of its markets and fairs. From that time every mean which a narrow and illiberal policy could devise, was employed to retard the growing prosperity of this port; but towards the conclusion of last century, many of the unjust restrictions which formerly subsisted were removed, and the different trades permitted to be followed without molestation. It was only, however, in the year 1804, that North Shields obtained the privilege of holding a weekly market and fairs, by petition of the inhabitants to the duke of Northumberland, as lord of the manor of Tynemouth, in which the site of North Shields is included. The day of the first opening of the market was ushered in with great rejoicings, and at noon a salute of cannon announced the completion of the long wished-for event. The market-day is Friday, and the fairs are held on the last Friday in April, and the first Friday in November.

North Shields, from these circumstances, and the patriotic exertions of the duke of Northumberland, is become, in the course of a few years, a large and populous town. It contains many handsome streets, and two elegant squares, besides the market-place, lately formed, which may rival any provincial market-place in the kingdom. On one side is a spacious quay, with a crane for the delivery of goods, where ships of 300 tons burthen may discharge or take in cargoes with perfect safety. Another side is adorned with a noble stone building, which is now used as an inn, and is surmounted with the Percy arms. North Shields, forming part of the parish of Tynemouth, has no parish church, but it possesses several chapels of ease, and meeting-houses for almost every class of dissenters. The other public structures and establishments here are a theatre, a dispensary, and a large school-house, erected by subscription, in commemoration of the royal jubilee, where a great number of boys and girls are educated on the Lancastrian plan. Here are likewise many well-conducted and flourishing benefit societies, an asylum for sick and friendless seamen, and a lying-in-hospital. A subscription library has also been opened in North Shields, and is said to contain an extensive collection of valuable books.

The harbour of North Shields is calculated to accommodate 2500 sail of ships; and in spring tides, vessels of 500 tons burthen can pass the bar without danger. The vessels belonging to this port, exclusive of small coasters, are stated in the "Historical View of Northumberland," to amount to 1000; but this number, we presume, includes the shipping of Newcastle and South Shields also, of which North Shields may justly claim one half. One great inconvenience complained of by the commercial interest here and at South Shields, is the want of an independent custom-house; which obliges the captains of all vessels sailing from this port to clear their ships at Newcastle, a distance of ten miles up the river.

The principal trade of North Shields, as of the river Tyne generally, consists in the exportation of coals to London, and other parts of the eastern coast of England; but some vessels are likewise employed in the Baltic and American trade; and during the late wars, a great number was

hired to government for the transport service. The manufactures established here are chiefly such as depend upon the shipping interest, as ship and boat-building, rope and sail-cloth making, brewing, baking, &c.; but there are likewise in North Shields a foundry for cast iron, an extensive tannery, one skinners, a tobacco manufactory, a glove manufactory, and five hat manufactories.

The seamen of this port are frequently very riotous and turbulent, when they want a rise of wages, or are in any way dissatisfied with the conduct of the ship-owners. In these instances they have generally acted upon a regular plan; forcing every sailor to remain on shore, and preventing any vessel from proceeding to sea until their demands were complied with. An alarming combination of this kind was formed in the months of September and October last, (1815), and threatened such serious consequences, as to render government interference necessary, when order was happily restored without bloodshed.

North Shields, according to the parliamentary returns of 1811, contains 804 houses, and a population of 7699 persons.

For some further account of this port and the adjoining country, see the articles NEWCASTLE, TYNE, TYNEMOUTH, and South SHIELDS. A Historical and Descriptive View of the County of Northumberland, &c. two vols. 8vo. Newcastle, 1812.

SHIELDS, *South*, a market-town and sea-port in the parish of Jarrow, east division of Chester ward, and county palatine of Durham, situated directly opposite to North Shields, at the distance of 21 miles N.N.E. from the city of Durham, and 27.8 N.N.E. from London. Like North Shields, it owes its importance chiefly to the coal trade and shipping interest, but the proportion of manufactures carried on here is greater than at the former town. About fifty years ago this place possessed upwards of two hundred salt-pans, but that branch of business has greatly declined, and others of higher importance are substituted in its stead, as ship-building, and the manufacture of glass, soap, &c. South Shields was constituted a market-town by bishop Trevor, in the year 1770. The market-day is Wednesday, and there are two annual fairs, on the 24th of June and the 4th of September. The vessels belonging to this port amount to about 300 in number. The church, which is a chapel of ease under Jarrow, is evidently a structure of great antiquity; the style of its architecture being that of the Anglo-Norman era. Some antiquaries are of opinion that there was a Roman station at the point of land near South Shields, which forms the southern entrance into the Tyne, and the conjecture is certainly probable, though by no means authenticated as a fact.

South Shields, like North Shields, has of late years greatly increased in population and extent; but it is destitute of many of the advantages possessed by the other. Here are, besides the established church, several dissenting meeting-houses; also several benefit societies and charity-schools. The petty sessions for the east division of Chester ward are held in the town-house here, which is a respectable building, situated in the centre of the market-place. Most of the streets of this town, however, are narrow, and the houses very indifferently built. According to the parliamentary returns of 1811, it contains 528 houses, and a population of 9001 persons.

About two miles to the westward of South Shields is the village of Jarrow, celebrated for its monastery, which was originally founded about the year 685; but has since been frequently rebuilt. This religious house was dedicated to St. Paul, and appropriated to the reception of Benedictine monks.

monks. Its remains, together with the church of Jarrow, occupy the summit of an elevated ridge, but display little worthy of notice. The History and Antiquities of the County Palatine of Durham, by W. Hutchinson, 4to. 1778. Beauties of England and Wales, vol. vi. by E. W. Brayley, and John Britton.

**SHIFFNAL**, a market-town in the parish of Shiffnal, hundred of Brimstrey, and county of Salop, England, is situated at the distance of 19 miles E. by S. from Shrewsbury, and 143 miles N.W. from London. The market-day here is Friday weekly, and there are fairs on the 5th of August and the 22d of November. The petty sessions for Shiffnal division of the hundred are held here; but in other respects this town is a trifling place, the whole parish, which is extensive, and includes four townships, containing, according to the parliamentary returns of 1811, only 808 houses, and 4061 inhabitants.

**SHIFT**, a term in *Music*, used for conducting the hand on the finger-board of the violin, and instruments with a neck.

By moving the left hand a little towards the bridge, and placing the first finger where the second was, on the second string of the violin, in the natural position of the hand, it will produce C instead of B, and the little finger will then produce C on the first string, its octave: and this is called the *half shift*. The first, or *whole shift*, is placing the first finger where the third was, in the natural position of the hand, which will produce D on the second string, and the little finger its octave on the first. The next movement of the hand towards the bridge is placing the first finger on E of the second string, when the little finger will give its octave on the first string, and this is termed the *double shift*; each shift commanding all the intermediate notes of an octave to the first finger. By this means a half, a whole note, or any number of notes, may be gained upwards upon each string, to the end of the finger-board. A readiness at these shifts, on short notice, in all keys, and in true intonation, is said to be *knowing the finger-board well*. At present (1809) high solo parts for the violoncello are written in the treble clef.

**SHIFT**, in *Ship-Building*, a term applied to disposing the butts of the planks, &c. so that they may over-launch each other, without reducing the length, and so as to gain the most strength. The planks of the bottom, in British-built ships of war, have a six-foot shift, with three planks between each butt, so that the planks run twenty-four feet long. In the bottoms of merchant-ships, they have a six-foot shift, with only two planks between each butt, making but eighteen-foot planks in length. The shift of the timbers is from three feet to ten feet six inches in length, according to the size of the ship.

**SHIFTED**, in *Sea Language*, denotes the state of a ship's ballast or cargo, when it is shaken from one side to the other, either by the violence of her rolling in a turbulent sea, or by an extraordinary inclination to one side, when under a great pressure of sail. This circumstance rarely happens, unless to those cargoes which are stowed in bulk, as corn, salt, and such materials.

**SHIFTED**, as expressed of the wind, implies *altered*.

**SHIFTER**, a person appointed to assist the ship's cook, particularly in washing, sleeping, and shifting the salt provisions.

**SHIFTING**, in *Ship-Building*, the act of setting off the length of the planks, &c. of a ship, so that the butts may over-launch each other, as to produce a good shift. (See **SHIFT**.) Replacing old stuff with new is also called shifting.

VOL. XXXII.

**SHIFTING a Tackle**, in *Sea Language*, the act of removing the blocks of a tackle to a greater distance from each other, on the object to which they are applied, in order to give a greater scope or extent to their purchase. This operation is otherwise called *flecting*.

**SHIFTING the Helm**, is altering its position from one side to the other, or from one side to midships.

**SHIFTING the Voyal**, or *Messenger*, changing its position on the capstern, so as to heave in the cable from the starboard or larboard side.

**SHIFTING of Plants**, in *Gardening*, the business of removing plants in pots, from smaller into larger ones, &c. to give them fresh earth or mould. It is necessary occasionally, in all plants in pots, to assist them with larger ones, according as the advanced growth of the particular sorts renders it proper; and at the same time to supply an additional proportion of fresh earth about the root-fibres of the plants, to promote their growth: and sometimes, for the application of fresh compost, either in part or wholly, from the plants having remained long unremoved, and the old earth in the pots being much decayed, or on account of some defect of growth in the particular plants.

In regard to the necessity of shifting, it is, in some degree, according to the advancing growth of the different sorts of plants: some sorts of a strong free growth require shifting once every year or two: others, more moderate growers, or of more settled growths, once in two or three years; and some large growing kinds, which are advanced to a considerable size, having been occasionally shifted, in their increasing growth, from smaller into larger pots of different proportionable sizes, and some from large pots into tubs of still larger dimensions, as large plants of the American aloe, orange, and lemon-tree kinds, &c. in that advanced state, sometimes only need occasional shifting once in three or several years, especially when the pots or tubs are capacious, containing a large supply of earth, and are occasionally refreshed with some new compost at top, and a little way down, round the sides about the extreme roots. And in some small slow-growing plants, as in many of the succulent tribe, shifting them once in two or three years may be sufficient; other sorts want shifting annually into larger pots, according as they advance in a free growth, as the hardy and tender kinds of herbaecous and shrubby plants, &c. And some of the tender annual flower-plants, cultivated in pots, and forwarded in hot-bed, being planted first in small pots, want shifting, in their increasing growth, into larger sizes, once or twice the same season, as from April to the beginning of June, when being shifted finally into the requisite full-sized pots, they remain during their existence. But though large-grown plants, either of the shrub or tree kind, as well as other plants of large growth, after being finally stationed in the fullest-sized large pots and tubs, succeed several years without shifting, they should in the interval have the top earth loosened, and down round the sides to some little depth, removing the loosened old soil, and filling up the pots, tubs, &c. with fresh earth, setting it close by a moderate watering.

The usual season for occasional shifting such plants as require it, is principally the spring and autumn, as from March to May for the spring shifting; and from August to the end of September for the autumn; though in plants that can be removed with the full ball of earth about the roots, it may be occasionally performed almost at any time; however, for any general shifting, the spring and autumn are the most successful seasons, as the plants then take fresh root; and many sorts preferably in the spring, by having the benefit of the same growing season, and that of sum-

mer. In performing the business, it is mostly proper to remove the plants from the smaller to the larger pots, with the balls of earth about the roots, either wholly, or some of the outward old earth, the dry or matted radical fibres only being carefully trimmed away, so as not to disturb the principal roots in the bodies of them, as by this means the plants receive but little check in their growth by the removal. Sometimes, when any particular plants, shrubs, or trees, &c. in their pots, discover by their tops that they are in a declining state, as probably the defect may be either in the root, or the old balls of earth, it may be proper to shake all the earth entirely away, in order to examine the roots, and to trim and dress them as the case may require, replanting them in entire fresh compost or mould.

And in preparing for this sort of work, where necessary to give larger pots, &c. it is proper to provide them of suitable sizes, in some regular gradation larger than the old ones, according to the nature and growth of the plants, the whole being placed ready, with a proper quantity of fresh compost earth, in proportion to the number and size of the plants intended to be shifted: then let those plants intended to be removed with balls, be taken out of their old pots separately, with the whole balls or clumps of earth about the roots as entire as possible; and when large, or tolerably full, with a knife trim off some of the outward loosest earth, and the extreme fibres of the roots; but when small, and adhering together compactly, the whole may be preserved entire; and in either case, where there are very matted, dry, or decayed fibres surrounding the balls, they should be trimmed as it may seem necessary: in those of a fresh lively growth, the loose straggling parts only should be cut away. The requisite pruning, trimming, or dressing in the heads or tops, should also be given where it may seem proper, according to the state of growth, and the natural habit of the different plants; but many sorts require little or none of this sort of attention.

Then having prepared the intended pots for the reception of the plants, by placing some pieces of tile or oyster-shell, &c. loosely over the holes at bottom, and laid in a little fresh earth, two, three, or four inches deep, or more, according to the size of the pot, the plant should be set in with its ball of earth, as above, filling up around it with more fresh mould, raising it an inch or two over the top of the ball; and giving directly a moderate watering, to settle the earth close about the ball and roots regularly in every part, in a proper manner: in such cases where the ball in particular plants appears very compactly hard and binding, it may be proper to loosen it a little, by thrusting a sharp-pointed stick down into the earth in different parts, giving it a gentle wrench, to open the earth moderately; or sometimes it may also be proper to trim away some of the old earth on the top and sides, then planting it as above, and filling up round and over the ball with fresh earth, and watering it afterwards.

Also, in shifting hardy or tender, shrubby, succulent, or herbaceous plants, when any appear of a sickly, weak, or unhealthy growth, it may be advisable to clear off a considerable part of the outward old earth from the balls about the roots, or, in some cases, to shake it wholly away, that the defects in the growths, occasioned either by faults in the roots or in the earth, may be removed by pruning out any decayed or bad parts of the roots, and replanting them wholly in fresh earth.

And sometimes particular sorts of plants in pots require shifting, more for the advantage of having fresh earth, than for want of new, or larger pots; and as in this case some of the same pots may be still of an eligible size to repot them in, these pots should be well cleaned from all the adhering parts

of the old earth, and be replenished with entire new, at the time of repotting the plants; which being removed out of their pots, either with the entire balls about the roots, and part of the old mould cleared off all round, to admit of a larger portion of fresh earth in the pot at replanting; or in some, appearing of an infirm or declining habit, the whole balls of old earth displaced clean to the roots; then having furnished the pots with fresh earth, the plants should be replaced in them, filling up the pots regularly with a sufficiency of the same fresh mould, and finishing with a moderate watering to settle the whole close about their roots.

Likewise after shifting, when the plants are not watered at the time, a moderate watering, both to the earth in the pots to settle it close about the roots, and in most sorts highly over the tops or heads of the plants, should be given, in order to wash off any foulness; then the pots of plants should be set in their respective stations in the garden, &c.: the hardy kinds, if warm sunny weather, may be placed in a shady border for two or three weeks, till they have struck fresh root in the new earth: the tender sorts should be disposed in their places among the green-house and stove-plants, or to have the benefit of shade in the middle of hot sunny days, till fresh struck, or probably some of the more tender particular sorts may require to be plunged in a hot-bed or bark-bed, especially some of the stove kinds: some principal sorts of the more curious or tender green-house plants, in order to expedite their fresh-rooting more effectually; and sometimes tender annuals in hot-beds, potted in their early young growth, may require to be replunged in the hot-bed to fresh strike, and forward them till June; but generally all the full ground or open air plants only require a little occasional shade in hot dry weather the first two or three weeks, and some shifted with full balls about the roots, only need occasional watering; afterwards, on the whole, both the hardy and tender kinds should have repeated moderate waterings given them, according to their kinds.

SHIFTS, such parts of a farm as are allotted for the reception of either stock or crops. It is also a term applied to the rotations of cropping lands: thus we have three, four, five, and six-course shifts. See *Course of CROPS*.

SHIJASCHKOTAN, in *Geography*. See SYASKUTAN.

SHIITES, in the *History of Mahometan Sects*, were the opponents of the *Kharejites*; see that article. This name properly signifies *sectaries* or *adherents* in general, but is peculiarly used to denote those of Ali Ebn Abi Taleb; who maintain him to be lawful caliph and imam, and that the supreme authority, both in spirituals and temporals, of right belongs to his descendants, notwithstanding they may be deprived of it by the injustice of others, or their own fear. They also teach, that the office of imam is not a common thing, depending on the will of the vulgar, so that they may set up whom they please; but a fundamental affair of religion, and an article which the prophet could not have neglected, or left to the fancy of the common people; nay some, thence called Imamians, go so far as to assert, that religion consists solely in the knowledge of the true imam. The principal sects of the Shiites are five, which are subdivided into an almost incredible number; so that some understand Mohammed's prophecy of the seventy odd sects, of the Shiites only. Their general opinions are, 1. That the peculiar designation of the imam, and the testimonies of the Koran and Mohammed concerning him, are necessary points. 2. That the imams ought necessarily to keep themselves free from light sins as well as more grievous. 3. That every one ought publicly to declare who it is that he adheres

heres to, and from whom he separates himself, by word, deed, and engagement, and that herein there should be no dissimulation. But in this last point some of the Zeidians, a sect so named from Zeid, the son of Ali, furnished Zein al Abedin, and great grandson of Ali, dissented from the rest of the Shiites. As to other articles, wherein they agreed not, some of them came pretty near to the notions of the Motazalites, others to those of the Mofhabbebités, and others to those of the Sonnites. Among the latter of these, Mahommed al Baker, another son of Zein al Abedin's, seems to claim a place: for his opinion as to the will of God was, that God willeth something *in* us, and something *from* us; and that he willeth *from* us he hath *revealed* to us; for which reason he thought it propolterous that we should employ our thoughts about those things which God willeth *in* us, and neglect those which he willeth *from* us: and as to God's decree, he held that the way lay in the *middle*, and that there was neither compulsion nor free liberty. A tenet of the Khattabians, or disciples of one Abu'l Khattáb, is too peculiar to be omitted. These maintained paradise to be no other than the *pleasures of this world*, and *hell-fire* to be the *pains* thereof, and that the world will never decay: which proposition being first laid down, it is no wonder they went farther, and declared it lawful to indulge themselves in drinking wine and whoring, and to do other things forbidden by the law, and also to omit doing the things commanded by the law.

Many of the Shiites carried their veneration for Ali and his descendants so far, that they transgressed all bounds of reason and decency; though some of them were less extravagant than others. The Gholaites, who had their name from their *excessive* zeal for their imams, were so highly transported therewith, that they raised them above the degree of created beings, and attributed divine properties to them; transgressing on either hand, by deifying of mortal men, and by making God corporal: for one while they liken one of their imams to God, and another while they liken God to a creature. The sects of these are various, and have various appellations in different countries. Abd'allah Ebn Saba, (who had been a Jew, and had asserted the same thing of Joshua the son of Nun,) was the ring-leader of one of them. This man gave the following salutation to Ali, *viz. Thou art Thou, i. e. thou art God*: and hereupon the Gholaites became divided into several species; some maintaining the same thing, or something like it, of Ali, and others of some of one of his descendants; affirming that he was not dead, but would return again in the clouds, and fill the earth with justice. But howmuchsoever they disagreed in other things, they unanimously held a *metempsychosis*, and what they call *al Holul*, or *the descent of God on his creatures*; meaning thereby that God is present in every place, and speaks with every tongue, and appears in some individual persons; and hence some of them asserted their imams to be *prophets*, and at length *gods*. The Nofairians and the Ishakians taught that spiritual substances appear in grosser bodies; and that the angels and the devil have appeared in this manner. They also assert that God hath appeared in the form of certain men; and since, after Mohammed, there hath been no man more excellent than Ali, and, after him, his sons have excelled all other men, that God hath appeared in their form, spoken with their tongue, and made use of their hands, for which reason, say they, *we attribute divinity to them*. And to support these blasphemies, they tell several miraculous things of Ali, as his moving the gates of Khaibar, which they urge as a plain proof that he was endued with a particle of divinity, and with sovereign power, and that he was the person in whose

form God appeared, with whose hands he created all things, and with whose tongue he published his commands; and therefore they say he was in being before the creation of heaven and earth. In so impious a manner do they seem to wrest those things which are said in scripture of Christ, by applying them to Ali. These extravagant fancies of the Shiites, however, in making their imams partakers of the divine nature, and the impiety of some of those imams in laying claim thereto, are so far from being peculiar to this sect, that most of the other Mohammedan sects are tainted with the same madness; there being many found among them, and among the Sufis especially, who pretend to be nearly related to heaven, and who boast of strange revelations before the credulous people. To this account of the Shiites of the first ages we shall subjoin a brief mention of the great schism at this day subsisting between the Sonnites and the Shiites, or partisans of Ali, and maintained on either side with implacable hatred and furious zeal. Though the difference arose at first on a political occasion, it has, notwithstanding, been so well improved by additional circumstances, and the spirit of contradiction, that each party detest and anathematize the other as abominable heretics, and farther from the truth than either the Christians or the Jews. The chief points wherein they differ are, 1. That the Shiites reject Abu Beer, Omar, and Othman, the three first caliphs as usurpers and intruders; whereas the Sonnites acknowledge and respect them as rightful imams. 2. The Shiites prefer Ali to Mohammed, or, at least, esteem them both equal; but the Sonnites admit neither Ali, nor any of the prophets, to be equal to Mohammed. 3. The Sonnites charge the Shiites with corrupting the Koran, and neglecting its precepts; and the Shiites retort the same charge on the Sonnites. 4. The Sonnites receive the *Sonna*, or book of traditions of their prophet, as of canonical authority; whereas the Shiites reject it as apocryphal and unworthy of credit. And to these disputes, and some others of less moment, is principally owing the antipathy which has long reigned between the Turks, who are Sonnites, and the Persians, who are of the sect of Ali. Sale's Koran, Introd.

SHILACON, in *Geography*, a town of Egypt, on the E. side of the Nile; 8 miles N. of Cairo.

SHILL, in *Agriculture*, provincially to separate the rind, husk, or skin, as of oats, or other crops. It also signifies the turning a small portion of milk into curd.

SHILLAY, in *Geography*, a small island near the W. coast of the island of Lewis; 5 miles W.S.W. of Toe Head. N. lat.  $54^{\circ} 48'$ . W. long.  $7^{\circ} 14'$ .

SHILLELAH, a town of Algiers, anciently *Turaphilum*; 10 miles S.W. of Burg Hamza.

SHILLER-STONE, or SHILLER-Spar, in *Minerology*, the diallage metalloide of Haiy, a mineral nearly allied to serpentine. (See SERPENTINE.) It is considered by some mineralogists as a crystalline variety of that rock; in which it generally occurs, either in beds or disseminated. Its colour is commonly olive-green, with a shining lustre, which is sometimes semi-metallic. The structure is lamellar, with joints in one direction: it yields to the knife. In the vicinity of New Radnor, in Wales, there is a rock of this mineral intermixed with steatite.

SHILLING, an English silver coin, equal to twelve pence, or the twentieth part of a pound.

Froherus derives the Saxon *scilling*, whence our *scilling*, from a corruption of *siliqua*; proving the derivation by several texts of law, and among others, by the twenty-sixth law, *De annuis legatis*. Skinner deduces it from the Saxon *scild*, *shield*, by reason of the escutcheon of arms upon it.

Bishop Hooper derives it from the Arabic *sheele*, signifying

## SHILLING.

fyng a *weight*; but others, with greater probability, deduce it from the Latin *scillicus*, which signified in that language, a *quarter of an ounce*, or the forty-eighth part of a Roman pound. In confirmation of this etymology, it is alleged, that the shilling kept its original signification, and bore the same proportion to the Saxon pound, as *scillicus* did to the Roman and the Greek, being exactly the forty-eighth part of the Saxon pound; a discovery which we owe to Mr. Lambarde. *Explicatio Rerum et Verborum* in Legg. Sax. voc. *Libra*.

Others say, that the shilling was at first a German appellation, *schilling*; coins of which name had been struck at Hamburgh in 1407.

However, the Saxon laws reckon the pound in the round number at fifty shillings, but they really coined out of it only forty-eight; the value of the shilling was five-pence; but it was reduced to four-pence above a century before the Conquest; for several of the Saxon laws made in Athelstan's reign, oblige us to take this estimate. Thus it continued to the Norman times, as one of the Conqueror's laws (Legg. Sax. p. 221.) sufficiently ascertains; and it seems to have been the common coin by which the English payments were adjusted. After the Conquest, the French *solidus* of twelve-pence, which was in use among the Normans, was called by the English name of shilling; and the Saxon shilling of four-pence took a Norman name, and was called the *groat*, or great coin, because it was the largest English coin then known in England.

The groat, from the French *gros*, a large piece, was introduced by Edward III. in 1354, and continues, though not in common circulation, to this day. The half-groat, or two-pence, is of the same date and continuance. In Scotland, about the year 1553, were first coined testoons, or shillings, bearing the bust of the queen, and the arms of France and Scotland on the reverse: they being of the same intrinsic value as those of England, were then worth four shillings, and the half-testoon two, Scottish money.

It has been the opinion of bishops Fleetwood and Gibson, and of the antiquaries in general, that though the method of reckoning by pounds, marks, and shillings, as well as by pence and farthings, had been in constant use even from the Saxon times, long before the Norman conquest, there never was such a coin in England as either a pound or a mark, nor any shilling or testoon, till the year 1503, 1504, or 1505; but in the twentieth year of king Henry VII. (A.D. 1505,) a few silver shillings, or twelve-pences, were coined, being about one-half the size of the modern shillings, or forty out of a pound weight of silver, which were fair and broad pieces. These, however, it is said, have long since been solely confined to the cabinets of collectors.

Mr. Clarke combats this opinion, alleging, that some coins mentioned by Mr. Folkes, under Edward I. were probably Saxon shillings new minted, and that archbishop Aelfric (Gram. Saxon. p. 52, at the end of Somner's Saxon Diction,) expressly says, that the Saxons had three names for their money, *viz.* mancuses, shillings, and pennies. He also urges the different value of the Saxon shilling at different times, and its uniform proportion to the pound, as an argument, that their shilling was a coin; and the testimony of the Saxon gospels, in which the word we have translated *pieces of silver*, is rendered shillings, which, he says, they would hardly have done, if there had been no such coin as a shilling then in use. Accordingly, the Saxons expressed their shilling in Latin by *scelus* and *argenteus*.

He farther adds, that the Saxon shilling was never ex-

pressed by *solidus*, till after the Norman settlements in England: and howsoever it altered during the long period that elapsed from the Conquest to the time of Henry VII. it was the most constant denomination of money in all payments, though it was then only a species of account, or the twentieth part of the pound sterling: and when it was again revived as a coin, it lessened gradually as the pound sterling lessened, from the twenty-eighth of Edward III. to the forty-third of Elizabeth. Clarke on Coins, &c. p. 120. 152. 155. 200. 376.

Silver farthings ceased with Edward VI., but the silver half-pence continued the sole coins till Charles II. The silver penny was much used to the end of the reign of George I., and so far from being no where to be found, as Hume asserts (Hist. vol. vi.), is superabundant of every reign since that period, not excepting even the present reign of George III.

In the year 1560, there was a peculiar sort of shilling struck in Ireland, of the value of nine-pence English, which passed in Ireland for twelve-pence. The motto on the reverse of these is, *POSUI DEUM ADJUTOREM MEUM*.

Eighty-two of these shillings, according to Malynes, went to the pound, they therefore weighed twenty grains one-fourth each, which is somewhat heavier in proportion than the English shilling of that time, sixty-two of which went to the pound, each weighing ninety-two grains seven-eighths; and the Irish shilling being valued at the Tower at nine-pence English, that is, one-fourth part less than the English shilling, it should, therefore, proportionably weigh one-fourth part less, and its full weight be somewhat more than sixty-two grains; but some of them found at this time, though much worn, weighed sixty-nine grains. In the year 1598, five different pieces of money of this kind were struck in England for the service of the kingdom of Ireland.

These were shillings to be current in Ireland at twelve-pence each; half shillings to be current at six-pence; and quarter shillings at three-pence.

Pennies and halfpennies were also struck of the same kind, and sent over for the payment of the army in Ireland. The money thus coined was of a very base mixture of copper and silver; and two years after there were more pieces of the same kinds struck for the same service, which were still worse; the former being three ounces of silver to nine ounces of copper; and these latter only two ounces eighteen pennyweights, to nine ounces two pennyweights of the alloy. Simon's Irish Coins.

The Dutch, Flemish, and Germans, have likewise their shilling, called *schelin*, *schilling*, *scalin*, &c.; but these, not being of the same weight or fineness with the English shilling, are not current at the same value. See *SCHILLING* and *SKILLING*.

The pound Flemish in accounts is divided into twenty shillings, and subdivided into twelve groots or pence Flemish. The coins in Holland are good shillings, or *escalins*, and half ditto, at six and three stivers; unstamped or base shillings reckoned at five and a half stivers, and called *schalks*. At Hamburgh, accounts are kept in shillings, sixteen of which are equal to a mark, and each containing twelve pfenings; and sometimes in pounds, shillings and pence Flemish; the pound being equal to twenty shillings, and the shilling equal to twelve-pence or grotes.

The English shilling is worth about twenty-three French sols; those of Holland and Germany about eleven sols and a half; those of Flanders about nine. The Dutch shillings are also called *sols de gros*, because equal to twelve gros.

The Danes have copper shillings, worth about one-fourth of a farthing sterling. See COIN.

SHILLUK, in *Geography*, a town of Africa, in the kingdom of Sennaar, on the E. side of the river Bahr-el-Abiad, and not far removed from it. This town is built of clay, and its inhabitants are idolaters. They have no other clothing than bands of long grafs, which they pass round the waist and between the thighs. They are all black, and those of both sexes shave their heads. The people of Shilluk have the dominion of the river, and take toll of all passengers, in such articles of traffic as pass among them. These people, who assume importance from their command of the river, are represented as hospitable to those who come among them in a peaceable manner, and as never betraying those to whom they have once avowed friendship; 50 miles W. of Sennaar.

SHILOH, in *Scripture Criticism*, a term that occurs in Jacob's celebrated prophecy concerning the Messiah (Gen. xlix. 10.); concerning the etymology and application of which, biblical commentators have differed in opinion. "The sceptre shall not depart from Judah, and a law-giver from between his feet; till *Shiloh* come; and to him shall the gathering of the people be." The word Shiloh, says one writer (Mr. Mann), is a modern reading; unknown in any other part of the scripture, or any of the old commentators; coined by the Jewish correctors of the bible into שִׁילֹה, a word of no signification; whereas the LXX read שִׁשְׁרִי, that is, שִׁשְׁרִי לֵי, he, to whom it is; he, to whom it, viz. the sceptre, belongs; ὁ ἀρχαῖος; he for whom it is reserved, as it is in the original best edition of the LXX version, as Justin Martyr long ago affirmed, (Dial. cum Tryph.), and as it now stands in the Alexandrian MS. And if this be the true meaning, it plainly refers to the king of the Jews; for whom the sceptre was reserved, and to whom the people were to be gathered. Mr. Ainsworth and some others render Shiloh the prosperor or safe-maker; others the peace-maker, from שִׁלְוָה; all which agree to the same person. But the most probable interpretation, as the author of Mordecai's Letters, (Mr. Taylor,) apprehends, is given us by the very learned and judicious Dr. Hunt, professor of Arabic at Oxford. He understands the true etymology of the word *Shiloh* to remain in the Arabic שִׁלְוָה, *shela*, liberavit, subduxit ab angustia et exitio. According to this etymology, *Shiloh* will be the deliverer from distress and destruction; a title, which justly belongs to Jesus Christ, the Lord of life, and Saviour of the world. If it should be objected to this etymology, that the *jod* (י) is wanting between the *shin* and the *lamed*, he observes, that in the Samaritan copy of Genesis, xlix. 10. the word is written without the *jod*, as it is likewise in one of the most ancient Hebrew MSS. which Dr. Kennicot has consulted on this text. Some moderns have pretended, in order to evade the prophetic force of this text, that the sceptre departed from Judah before the advent of Christ, by its falling into the hands of foreigners, which objection is sufficiently answered by Cuneus (De Republ. Heb. l. 50. c. 9.) and others: who have shewn, that the text only regards the continuance of the Jewish state; and that Judea, as separated from Israel, should remain a kingdom till the coming of the Messiah. On the other hand, Abrahamael and others suppose, that the sceptre is not yet departed from Israel; and Menasseh Ben Israel alleges, that it is still in the hands of the tribe of Judah. The ancients undoubtedly understood this text of the Messiah. The Chaldee Paraphrast says, "He that hath dominion shall not be taken away from Judah, nor a scribe from his children's children, until the

time when Christ shall come, whose the dominion is; and him shall the people (or nations) obey." And the Jerusalem Targum says, "Kings shall not cease from the house of Judah, nor doctors that teach the law from his children's children, until the time that Christ do come, whose kingdom is; and all the kings of the earth shall be subject unto him;" so that both the Targums confine the sense to this; that the peoples (*i. e.* both Jews and Gentiles) should gather unto and obey Christ: or, in other words, that the person here spoken of should be the prince that should reign over all; *πρωτοκρονατος*, as the LXX say in this place; and that this should happen before Judah should cease to be a kingdom: which is verified by fact. Ben Mordecai's Letters, Letter iv.

SHILOH, or *Silo*, in *Ancient Geography*, a famous city of Ephraim (Josh. xviii. xix. xxi.), 12 miles distant from Shechem or Siehem, according to Eusebius, or 10 miles according to Jerom, and situated, according to both, in Aerababene. In Jerom's time this city was ruined, nothing remaining but the foundation of the altar of burnt offerings, which had been erected when the tabernacle was there. At Shiloh, Joshua assembled the people to make the second distribution of the land of promise. (Josh. xviii. 1, 2, 3.) Here the tabernacle of the Lord was set up, when the people were settled in the country. (Josh. xix. 51.) The ark and the tabernacle of the Lord continued at Shiloh, from A.M. 2560, when it was set up by Joshua, to A.M. 2888, B.C. 1116, when it was taken by the Philistines, under the administration of the high-priest Eli. At Shiloh Samuel began to prophesy. (1 Sam. iv. 4.) Here the prophet Abijah dwelt. (1 Kings, xiv. 2.) Jeremiah foretold that the temple of Jerusalem should be reduced to the same condition as Shiloh was. (Jer. vii. 12. 14. xxxi. 6. 9.) After the return of the ark out of the country of the Philistines, instead of returning it to Shiloh, it was taken to Kirjath-jearim. (1 Sam. vi. 21.) Mr. Roland conjectures, that from the name Shiloh, Pausanias (l. vi. c. 24.) took occasion to say, that Sileus, the companion of Bacchus, was buried in Palestine. Benjamin of Tudela affirms, that the tomb of Samuel was to be seen here.

SHIM, in *Agriculture*, a tool of the tillage kind, used in breaking down and reducing the more stiff and heavy sorts of land, as well as cutting up and clearing them from weeds. They are made in different forms and constructions, to suit different purposes. In the Hertford Agricultural Survey by the Board of Agriculture, the writer remarks, that a tool of this kind is in use by Mr. Calvert, of Albury, which differs from those usually employed, in which the cutting-iron or plate, which for the work it is adapted for, as that of cutting up weeds on two-bout or four-furrow Elix ridges, or of cleaning land without ploughing or burying the soil, is a small segment of a large circle. It dispatches a ridge at a time, and is an implement that performs its business well, and which deserves the notice of the tillage-farmer in other places. It is readily altered for flat work, and is said to be had recourse to by other farmers with success in the same district.

And an useful tool of this sort has also been recommended by Mr. Young, in his Annals, the hant of which he took from the Berkshire one, and to which the beam and block is capable of being applied. In a wide interval, the three shares may be worked on a level. Between the rows of cabbage, after earthing up, the two external share may be set to cut the weeds that are apt to rise on the sides of the ridges, without disturbing too much earth, and the centre share sunk to scrape the bottom of the furrow. The centre one may also be worked alone, between narrow rows. In forging the shares of all thums, he has well observed, that

the blacksmith should be careful to give them tendency enough *into* the ground, by bending them downwards: for want of this caution, he has found many of them to work badly. The wheel in the beam counteracts this tendency sufficiently when at work.

These tools should be upon all tillage farms, in all their different and best constructions.

**SHIM** *Potatoe*, a tool of the shim kind, used for cleaning potatoe crops.

**SHIN, LOCH**, in *Geography*, an extensive lake in the county of Sutherland, Scotland. This lake extends above 20 miles in length, but no where exceeds two miles in breadth, and seldom above a mile and a half. The banks are finely covered with natural wood, particularly the southern bank. It is connected with the Northern ocean, at Dornoch Frith, by the river Shin, which abounds with salmon, and forms several falls in the short course of eight miles. Sinclair's Statistical Account of Scotland, vol. xi. 1794.

**SHINAAS**, a small town of Persia, in the province of Laristan. This and Bostana lie between Linga and Cape Bostana; but though they are small towns, they afford some refreshment. Linga, the chief town of the piratical tribe of Joasms in the Persian shore, is situated close to the sea, in N. lat.  $26^{\circ} 33'$ , about eight leagues from Kishm. It has a secure road, where ships may ride out a north-west gale in five fathoms water. Cape Bostana forms to the eastward the roadstead of the town of Mogoo, which is one of the most secure in the gulf; and this roadstead has to the westward the point improperly called Cortes. This roadstead is capable of holding the largest fleets.

**SHINDAN**, a mountain of Persia, between the provinces of Adirbeitzan or Azerbaijan and Ghilan.

**SHINGARIN**, a town of Africa, in the country of Sahara, where salt is found; 9 miles N. of Walet.

**SHINGEIAT**, a town of Africa, in the country of Bergoo; 90 miles W. of Wara.

**SHINGLE**, in *Agriculture*, a term sometimes applied to the thinings of fir and other timber trees, in the northern districts, and which are of much use for various purposes in farming, as the making of fences, &c.

**SHINGLE**, a substance found and collected on the sea-beach, or shore, which is used for several purposes, as ballasting of ships, filling surface hollow drains, protecting the foundations of embankments, and other similar uses. See *SURFACE Drain*, and *SURFACE Draining*.

It is said to be a very valuable substance for the use of filling drains, as being particularly durable in its nature. In the county of Suffex, as well as in Essex, much of it is made use of in this way; in the former, under the denomination of sea-beach, or beach.

**SHINGLE Shoal**, in *Geography*, a shoal in the English Channel, near the coast of Hampshire. N. lat.  $50^{\circ} 38'$ . W. long.  $1^{\circ} 26'$ .

**SHINGLES**. See **SHAMBLES**.

**SHINGLES**, or *Shides*, in *Building*, small pieces of wood, or quartered oaken boards, sawed to a certain scantling, or more usually cleft to about an inch thick at one end, and made like wedges, four or five inches broad, and eight or nine inches long. They are used in covering, especially for churches and steeples, instead of tiles or slates.

This covering is dear; yet where tiles, &c. are very scarce, and a light cover is required, it is preferable to thatch. If made of good oak, and cleft, not sawed, and well seasoned, shingles make a sure, light, and durable covering.

The building is first to be covered all over with boards, and the shingles then nailed thereon.

**SHINGLES**, in *Medicine*, the popular appellation of a vesicular eruption, which appears on the trunk of the body, extending generally half round, like a belt: whence probably the term is a corruption of the Latin word *cingulus*, or *cingulum*, signifying a belt. It is the *herpes zoster* of medical writers, the Greek word, ζοστής, having the same signification. It is sometimes called simply *zona*, or *zoster*. For the description and treatment of this curious and harmless, though sometimes painful, affection, see **HERPES Zoster**. See also Bateman's Practical Synopsis of Cutaneous Diseases, p. 226.

**SHINGLING**, in the *Iron-Works*, in many parts of England, is the operation of hammering the sow, or cast iron, into blooms. The tongs, used for holding the iron in this operation, are called shingling-tongs, and the iron to be thus wrought is called a loop.

**SHINING MOUNTAINS**, in *Geography*, mountains that bound Louisiana on the west, which, though little known, are supposed to terminate in N. lat.  $47^{\circ}$  or  $48^{\circ}$ ; whence spring a number of rivers, that discharge themselves into the North Pacific ocean, Hudson's bay, the waters which lie between them, or the Atlantic ocean. They are also called the "mountains of bright stones," on account of the immense number of large crystals shooting from the rocks, and sparkling in the rays of the sun, so as to be seen at a great distance.

**SHIOBERT** *el Yemeni*, a town of Egypt, on the right bank of the Nile; 8 miles S.E. of Mehallet Kebir.

**SHIONKAN**, a town of Pegu; 8 miles N. of Sirian.

**SHIP**, a general name for all large vessels navigated with sails. Among people unacquainted with marine distinctions, this term has a very vague and indiscriminate acceptation. In the sea-language, however, it is more particularly applied to a vessel furnished with three masts, each of which is composed of a lower mast, topmast, and top-gallant mast, with the usual rigging and appendages thereto belonging.

The sieur Aubin defines a ship, a timber building, consisting of various parts and pieces, nailed and pinned together with iron and wood, in such form, as to be fit to float, and to be conducted by wind and sails from sea to sea.

The invention of ships is very ancient, and, at the same time, very uncertain. Mythologists attribute it to Dædalus, and pretend that the wings he invented to save himself withal from the labyrinth of Crete, were nothing but sails, which he first gave to vessels, and with which he eluded the vigilance and pursuit of Minos. Others give the honour to Janus, on the credit of some ancient Greek and Latin coins, on one side of which is represented his double face, and on the reverse a ship. Lastly, others look on Noah to have been the first ship-builder.

The most celebrated ships of antiquity are, that of Ptolemy Philopater, which is said to have been two hundred and eighty cubits (*i. e.* four hundred and twenty feet) long, thirty-eight broad, and forty-eight high: it carried four thousand rowers, four hundred sailors, and three thousand soldiers. That which the same prince made to sail on the Nile, we are told, was three hundred and twelve feet long, forty-five feet broad, with a mast one hundred and twenty feet high. Yet these were nothing in comparison with Hiero's ship, built under the direction of Archimedes, on the structure of which Mofchion, as we are told by Snellius, wrote a whole volume. There was wood enough employed in it to make sixty gallees. It had all the variety of apartments

## SHIP.

ments of a palace: banquetting-rooms, galleries, gardens, fish-ponds, stables, mills, baths, a temple of Venus, &c. It was encompassed with an iron rampart, and eight towers, with walls and bulwarks, furnished with machines of war, particularly one, which threw a stone of three hundred pounds, or a dart twelve cubits long, the space of half a mile; with many other particulars related by Athenæus. Deipnosophist. lib. v. p. 204, &c. ed. Caufab. Lugd. 1657.

A ship is undoubtedly the noblest machine that ever was invented, and consists of so many various parts, that to form some idea of its importance and qualities will require the attention of the gentleman and the artist.

All ships at first were of the same form, whatever uses they were designed for; but the various ends of navigation, some of which were better answered by one form, some by another, soon gave occasion to build and fit out ships, not only different in size, but also in their construction and rigging: and as trade gave occasion to the fitting out large fleets of different kinds of merchant-ships, so ships of war became necessary to preserve them to their just owners.

The gradually improving state of shipping, in the last century, has kept pace with the regular advancement of every other branch of mechanical science. For, prior to that period, even our first-rate ships, now equal in perfection to those of any other rate, were then extremely defective, as their want of stability made their magnitude highly objectionable. These disadvantages have been gradually obviated, since the usual causes of instability have been discovered, the dimension enlarged, and the practical management familiarized; and they are now, in general, especially those that have most stability, admirable ships in most respects; as they sail well, and combine almost every good quality. Large as they are, they are perfectly manageable; and their evolutions are generally made with wonderful facility.

*Second-rate ships*, or those about ninety guns, have too generally those defects in their construction, which contribute to instability, arising from want of that capacity which most of the first-rates possess. The French, on this account, have discontinued this class of shipping.

*Third-rate ships*, or those of eighty and seventy-four guns upon two decks, are altogether the most useful and valuable ships in the navy; and possessing, in an eminent degree, all the properties of capacity, stability, and swiftness; the particulars of which last property will be found hereafter under SHIP-BUILDING, and this ship may be considered as the first of its class, from its great length and superior capacity.

The above are particularly distinguished as line-of-battle ships, and are found in general to suit the most powerful exigencies of the naval services. About ten years ago an additional lieutenant was appointed to the line-of-battle ships. See RATE.

*Fourth-rate ships* are those of fifty guns. They may be employed, if necessary, in the line-of-battle, but most suitable to be stationed amongst the foreign colonies, or on ex-

peditions of great distance; since these vessels are usually excellent for keeping and sustaining the sea.

*Fifth-rate ships* are frigates of from forty-four guns to thirty-two guns upon one deck, and even to fifty guns in America, (being restricted formerly to vessels of war with one deck); and though too weak to suffer the shock of a line-of-battle, they are very useful to accompany fleets, to lead the convoys of merchant-ships, to protect colonial commerce, to cruise in different stations, or to be sent expressly with necessary intelligence and orders.

The forty-four gun frigate being the most powerful, and most valuable of this class, has induced us to give a plate of one, so constructed as to have all the qualities which can possibly be united in one ship; for having but one deck, her breadth and height are so proportionable to her length, that she may be brought down in the water to that depth which is allowed to be the best sailing trim for ships in general. Ships of fifty and thirty-eight guns have four lieutenants. See RATE.

The *sixth-rate* includes all the smaller class of vessels in the navy, except the yacht, fire-ship, and bomb-vessel: they are classed as fifth-rates, to increase the pay; the former by way of distinction, the latter on account of the dangers to which they are exposed. Frigates of twenty-eight, twenty-four, and twenty guns, are in this class; but those with the thirty-two gun ship, in the former class, are so inferior to the forty-four and thirty-six gun frigate, as not to deserve notice nor continuance by a great maritime power. Ships of twenty guns, and all vessels upon the establishment of fleets of war, have two lieutenants. See RATE.

The large sloop of war and brig are very serviceable vessels to cruise against privateers, contraband trade, and for small convoys. Some of the latter have lately been built in this country, and are admirably adapted for good sea-boats, as well as good sailers; their upper works being light, all unnecessary top-hamper avoided, having a snug stern, and apparently every good quality that can be expected in a vessel of this description.

One of these vessels, the Raven, upon being fitted for sea at Woolwich, under the directions of her very ingenious and active commander, captain William Layman, had, agreeably to his recommendation and wishes, among other alterations, the two foremost ports closed up, and the guns taken away; in lieu of which was fitted in midships, immediately before the fore-mast, a sixty-eight pounder carronade upon a fixed traverse carriage, so as to fire in almost every direction clear of the gunwale; and, in lieu of the two stern-chasers, a carronade of the same power, upon an inclined plane abaft. The wonderful accession of force derived from these alterations, and the great advantages to be derived from them in chase, in clearing an enemy's coast, &c. are too obvious to need comment.

Ships in the royal navy are commanded by post-captains to 22 guns; sloops by master and commander.

The following Table furnishes a correct list of the dimensions of ships of different rates. See RATE, under which article a less perfect table is inserted.

*Yacht*, as a vessel of state, is usually employed to convey princes, ambassadors, or other great personages, from one kingdom to another, or even kings, to take pleasure in; of which our present gracious majesty was very fond. The Royal Sovereign yacht was launched for the particular service of his majesty at Deptford, in the year 1804; a ship whose exterior and interior are of incomparable beauty, but whose ornaments, splendid as they are, will scarcely be considered by the artist as more than adequate to the beauties of her form; and her qualities as an excellent sailer and good sea-boat, from experiment, stand unrivalled. We have, therefore, given a plate of this excellent vessel, by a quarter of an inch scale.

Yachts, as may be expected from the purposes for which they are designed, are the most beautiful of all vessels which navigate the ocean; nor are their superb embellishments and stately apartments their highest excellencies. They are models, in which may be seen a combination of the best principles of the art.

The *fire-ship* differs but little in its outer construction from a sloop of war. She may be built light and very clean for fast sailing; but the inner part is very differently fitted, in the manner described under the article *FIRE-Ship*.

The *bomb-vessel* is particularly constructed for throwing shells from a mortar. They are built very strong, and firmly rided; are usually fitted with two bomb-beds, which are

platforms or strong frames of thick stuff and timber, laid transversely over large beams, and are rabbeted and solidly bolted all together. The mortar-bed, or carriage which carries the mortar, traverses on a large iron pivot, in the centre of the bomb-bed, in a circular excavation. The sides of the bomb-bed, round the mortar, are fitted with strong cheeks of oak, of an octagonal form; in every square of which are driven two ring-bolts, for traversing the mortar in any direction. The bomb-bed underneath, to support the shock in throwing the shell, has three ranges of large pillars, six in a range, tenoned at the head and heel into large earlings fore and aft the bed, along the middle and sides, which are secured on the riders below, and into the beams above the pillars, standing double in the middle of the bed athwart-ships.

A strong compartment, called the shell-room, is built round the outside of the pillars. See *SHELL-Room*. See also *BOMB-Vessels* and *KETCH*.

*SHIP, Armed*. See *ARM*.

*SHIP, Guard*, is a vessel of war appointed to superintend the marine affairs in a harbour or river, and to see that the ships which are not commissioned have their proper watch kept duly, by sending her guard-boats around them every night: she is also to receive seamen who are impressed in time of war.

*SHIP, Hospital*, a vessel fitted up to attend on a fleet of men of war, and receive their sick or wounded; for which purpose

purpose her decks should be high, and her ports sufficiently large; her cables ought also to run upon the upper deck, to the end that the beds or cradles may be more commodiously placed between decks, and admit a free passage of the air, to disperse that which is offensive or corrupted. Falconer.

**SHIP, Lee-ward.** See *LEE-ward Ship*.

**SHIP, Merchant,** a vessel employed in commerce, to carry commodities of various sorts from one port to another.

Merchant shipping, in general, being scarcely definable into distinct classes, we cannot speak with that degree of precision of them as of those of the royal navy; because their respective forms and dimensions are dependent, almost entirely, on the local practice or ideas of their respective owners or constructors, and fluctuate accordingly. Those belonging to the East India Company are by far the largest, and are very fine ships, and of course rank in the first class of merchant ships. West India ships are little inferior to the former, but in size; and some of the largest have been employed occasionally either to the East or West Indies.

The East India ship (*Plate XII.*) has been actually built, and found upon trial to answer every purpose expected from her.

Some ships of a very fine model, being less burthenome than West India ships, are employed in the Straits' trade; and others used in the East country trade, for carrying of timber, exceed either of the latter for size, the largest of them being no less than 700 tons.

**SHIP of War, Private.** See *PRIVATEERS*.

**SHIP, Store,** a vessel employed to carry artillery or naval stores, for the use of a fleet, fortress, or garrison.

**SHIP, Transport.** See *TRANSPORT Ship*.

**SHIP, Troop.** See *TROOP Ship*.

We shall here observe in general, that it is highly necessary to the health of seamen, that ships should be cleared of foul air; for it has been found by frequent experience, that air shut up, and confined in a close place, without a succession and fresh supply of it, becomes unwholesome, and unfit for the use of life. This is more sensibly so, if any stagnating water be pent up with it. But it grows still worse, if such an air as this is made use of in respiration; that is, becomes moister, and hotter, and phlogisticated, by passing and repassing through the lungs.

These bad effects, in different degrees, according to the different manner in which air is inclosed, are observed in many cases, particularly in deep wells and caverns of the earth, in prisons or close houses, where people are shut up with heat and raielines; but most of all in large ships, in which, with the stench of water in the hold, many men being crowded up in those quarters, all the mentioned circumstances concur in producing greater mischiefs than would follow from any of them singly. For an account of Mr. Sutton's contrivance for clearing the holds of ships of the bad air contained in them, we refer to the article *AIR-Pipes*.

The mixture used sometimes for covering the bottom and sides of ships is made of one part of tallow, of one part of brimstone, and of three parts nearly of rosin. The tallow and rosin are melted together, and the brimstone is stirred into them; one hundred and forty pounds of brimstone will serve for a vessel of one hundred and forty tons. See *PAY*.

To prevent ships, whose bottoms are worm-eaten, from leaking, this method has been proposed. Caulk well the inside planks or linings, then fill the vacant spaces between the timber; and the out and inside planks, with boiling pitch or rosin, so high as the main gun-deck. The pitch being

put in very hot, will run into the smallest cranny, and make the ship as tight as a bottle. There will be no room left for vermin, as rats, &c.; and the pitch will serve for other uses when taken out, therefore the expence will be but small. Phil. Transl. N<sup>o</sup> 476. p. 372.

For the laws relating to ships, &c. see *Act of English NAVIGATION*. See also *FREIGHT, MARINERS, and NAVY*.

**SHIP, bulk, burden, captain, clerk, company, corporal, flag, grounding, master, mine, register, rigging, run, sheathing, squadron, stay, steward, warps, washing away, weather,** in reference to a ship, see the respective articles.

For further particulars respecting ships, the reader is referred to the article *SHIP-BUILDING*.

**SHIP, To,** in *Sea Language*, is used either actively, as to embark any person, or put any thing aboard ship; or passively, to receive any thing into a ship; as we shipped a heavy sea, &c.

*To ship* also implies to fix any thing in its place, as *to ship* the oars; *to ship* the swivel guns, &c. to fix them in their sockets, &c.

**SHIP of Pleasure,** among the *Ancients*. See *THALAMEGUS*.

**SHIP,** in the *Salt Works*, is a large cistern, out of which the salt-pans are supplied for boiling.

This cistern is built close to the saltern, and is made either of wood, brick, or clay; and it ought always to be covered with a shed, that the sea-water, contained in it, may be kept clean from soot, and other impurities, and not mixed with fresh water in rains; and it must be always placed to high, that the water may easily run out of it into the pans, to supply them for boiling.

**SHIP Guns.** See *CANNON*.

**SHIP Cove,** in *Geography*, a cove of Queen Charlotte's found, in the southern island of New Zealand. This harbour, according to captain Cook, is not inferior to any found, either for convenience or safety. It lies on the west side of the island, and is the southernmost of three coves, that are situated within the island of Motuara, which bears east of it. Ship Cove may be entered either between Motuara and a long island called by the natives Hamote, or between Motuara and the western shore. In the last of these two channels are ledges of rocks, three fathoms under water, which may be easily known by the sea-weed that grows upon them. S. lat. 41 10'. E. long. 175° 6'.

**SHIP Island,** a small island in the gulf of Mexico, near the coast of West Florida, nine miles long and two broad. It produces pine-trees and grass, and has a tolerable well of water. N. lat. 30 5'. W. long. 88° 48'.—Also, a small island of Upper Canada, in lake Erie.

**SHIP Point,** a cape on the coast of North Carolina. N. lat. 35 59'. W. long. 76° 30'.

**SHIP-BUILDING,** or *Naval Architecture*, is the art of constructing and raising, or budding that noble fabric called a ship.

This science, or whatever relates to navigation, is, without doubt, one of the most important and most useful employments of the human mind; especially in a country whose marine is its bulwark, and its commerce the admiration, and, we may add, the envy of the world.

Nevertheless, the scientific part of ship-building has been too much neglected; and although some few years have elapsed since mathematicians (particularly in France) have laboured with some success, yet their discoveries are so much enveloped in profound calculation; that ship-builders, in general, have scarcely been able to derive any advantage from them.

It must be allowed, that an exact knowledge of the

## SHIP-BUILDING.

true principles upon which the construction of ships, so as to answer the particular purposes of war or commerce, is founded, must conduce to remedy all the present defects, to render the theory more perfect, and enable the English artists to become as eminently skilful in the scientific, as they now confessedly are in the practical branches of ship-building.

In order to smooth the way in a science thought so incomprehensible, our readers must be made familiar with the several draughts and plans requisite to construct and raise so noble a body of architecture; for the proportional size of every part must be laid down, from whence the form and dimensions of the several timbers, and every particular part that enters into the construction, are to be obtained. Therefore, as a ship has length, breadth, and depth, three different plans at least are necessary to represent the form of the several parts of her; as in the sheer-draught, *Plate I.* of *Ship-building*, which comprehends the *sheer-plan*, the *body-plan*, and the *half-breadth plan*.

The *sheer-plan*, or, as it is called in civil architecture, the *plan of elevation*, is a vertical section, passing through the vessel in its whole length, or fore and aft. Upon this plan the length and depth of the keel are represented, also the height and rake of the stem and stern-post; the situation and height of the midship and other frames; the water-lines; heights of the decks, gun-ports, and wales; the centres of the masts; the situation of the channels; length and depth of the head and rails, quarter-galleries, rudder, &c. &c.

The *body-plan*, or *plan of projection*, to the left of the sheer-plan, is a transverse section of the ship at the midship-frame, or broadest place perpendicular to the keel. The several breadths, and the particular form of every frame-timber, are described on this plan. Now as the two sides of the ship are, or should be, exactly similar to each other, it is therefore unnecessary to represent both: hence the frames contained in the fore-body, between the midship-frame and the stem, are described on the right-hand side of the middle line, and the aftermost frames on the left of the said middle line.

The *half-breadth* or *floor-plan*, under the sheer-plan, and parallel thereto, or as it is frequently called, the *horizontal plan*, contains the several half-breadths at every frame-timber, at the different heights of the water-lines, main-breadth, top-side, ribband-lines, &c.

The consideration of these three principal plans is so much the more important, as it comprehends a sufficient knowledge of the figures of all vessels. For although these three plans do not really determine the figure of the vessel, and may belong to an infinity of different kinds, yet all these differences cannot exceed certain limits sufficiently confined; so that whatever idea we might form of the figure of the vessel, it cannot deviate considerably from the truth.

In order to explain this better, we will proceed to construct the sheer-draught, *Plate I.*; and here the nature, and all the properties of the vessel, according to her design for war or commerce, must be taken into consideration, upon which the whole theory of the art depends: such are, capacity, stability, velocity, and ease in the sea or at anchor. These properties are not to be adopted merely from speculative theory, but from those that have actually been demonstrated by repeated experiments. That our readers may have the clearest conception of the various parts of a ship, represented by the plates of the 74-gun ship, we will endeavour to describe them in as familiar a manner as possible, introducing also all that is necessary to be known as we proceed. The 74-gun ship is preferred as the medium

between the first-rate and the frigate, and is esteemed the most useful of all others.

Therefore, the first thing to be determined is the length on the gun-deck; and here sufficient distance must be allowed for the ports, which are fifteen in number, three feet five inches wide, or fore and aft, each, so as to have a sufficient distance between each port for working the guns, which is about seven feet eight inches; likewise room forward, between the foremost-port and the stem, for the manger; and also abaft the after-port, to the transoms: these considered make the length on the gun-deck 180 feet.

Draw therefore, as in sheer-plan, *Plate I.*, a straight line, which represents the upper edge of the keel, and in naval ships the upper edge of the rabbet (East India ships and merchant-ships in general have the rabbet in the middle of the keel), leaving under this line sufficient space for the main and false keels, scale, and half-breadth plan. Upon this line square up a perpendicular towards the right hand, leaving a sufficient space to represent the head, and call it the foremost-perpendicular; then, at  $22\frac{1}{2}$  inches abaft it, square up the after-perpendicular, which is 180 feet, by one-eighth of an inch to a foot, or the length on the gun-deck, from the aft-side of the rabbet of the stem to the fore-side of the rabbet at the stern-post. Below the upper edge of the keel, and parallel thereto, set down two feet for the main and false keel, and under it draw the scale of equal parts, of one-eighth of an inch to a foot, and from this scale set off all the following dimensions. Observe, draughts in general are drawn from a scale of one quarter of an inch to a foot, but this, for convenience, to one-eighth.

The length between the foremost and aftermost perpendiculars, in merchant-ships, is given from the aft-side of the stern-post, at the height of the wing-transom, to the fore-side of the stem, at the same height.

The stem, or fore-boundary of the ship, may now be drawn, and a segment of a circle for its lower part has long been considered as the best form for dividing the fluid; therefore, fix its centre so that the aft-side of the rabbet (which is in the middle of the stem, towards the upper part) may intersect the foremost-perpendicular at the height of the gun-deck: thus, set aft from the foremost-perpendicular, as in *Plate I.* upon an horizontal line, 24 feet above the upper edge of the keel, 24 ft. 3 in.; and from thence, as the centre, draw an arc of a circle from the upper edge of the keel-line, and another arc 18 inches before it, from the same centre; then will the moulding, or fore and after-sides of the stem, be represented: sweep likewise the rabbet, as in *Plate I.*; then set up 36 feet for the height of the head of the stem, and at that height set forward 15 inches from the foremost-perpendicular; from thence draw a faint curve, to intersect with the foremost segment, and the fore-part of the stem will be shewn: continue upwards another parallel thereto, and the aft-side or whole stem is completed, except the lower end or boxing, which will be determined hereafter.

The stern-post, or after-boundary under water, may be next drawn; thus, set up from the upper edge of the keel-line 26 ft. 10 in., which is the upper side of the wing-transom at the after-perpendicular, and upon that line set aft from the perpendicular 1 ft. 10 in., and upon the upper edge of the keel, six inches before the after-perpendicular; then a line drawn through these points will represent the aft-side of the stern-post; another line, drawn at fourteen inches before the aft-side of the stern-post, at the wing-transom, and at two feet one inch on the upper edge of the keel, will be

## SHIP-BUILDING.

the aft-side of the rabbet; and another line parallel four inches before it (or at the thickness of the bottom plank) is the fore-side of the rabbet, which will intersect the after-perpendicular at the gun-deck. Thus far the stern-post at present.

Having fixed on the length of the gun-deck, the next principal dimension to be considered is the main-breadth, and this, in ships of war in general, is about three-elevenths of the said length for their moulded breadth, and in merchant-ships about three-twelfths of their length; excepting cutters and smaller vessels. The moulded breadth given in *Plate 1.* of the 74-gun ship, is 48 feet.

Before we proceed, it will be necessary here to remark, that much has been said in regard to the breadth to be given to a vessel in respect to her length, and in what part of that length it is best to place it; as being the section of the greatest area of the whole vessel, its true situation becomes an object of importance.

Those who would diminish the breadth have alleged, and truly, that a narrow vessel meets with less resistance in passing through the water, and by increasing in length, the vessel will drive less to leeward, and the water-lines consequently be more delicately formed to divide the fluid; that a long narrow ship will require less sail to gain velocity, consequently the masts will be lower, the rigging lighter, and the vessel navigated by fewer hands. On the contrary, a ship's being broader at the line of flotation will admit of being narrower on the floor, particularly at the fore and after parts; that by being broader it can carry more sail, and more readily rise upon the waves than a narrow one. The breadth, and its situation, when determined on, require much skill in narrowing therefrom, as we approach the keel, particularly forward and aft, to give that form to the body under water that shall best answer in dividing the fluid, enable her to carry the lower tier of guns sufficiently out of the water, prevent her pitching, and give a free passage to the rudder, that she may readily answer her helm.

Now to prevent the vessel pitching, the fore-body must be so shaped, that its bearings should catch the vessel in its descent, that is, the harpin should increase in breadth upwards, and the bow be so formed, as rather to throw off the sea than pitch or bury in it: a long floor, with little rising afore and abaft, the displacement of the fore-body to be duly proportioned to the after-body, and hollow water-lines, or inflected curves at the fore part, are to be carefully avoided. Taking into consideration the weight of the anchors on the bows, we may easily conceive, that with the pressure of the wind upon the sails, without sufficient bearing in the fore-body, the bow would be pressed down into the hollow of every sea; and if the greatest area or midship-bend were placed too far aft, the support would only be in the after-body, and this would tend to plunge her bows still deeper, and retard her velocity, and the free passage of the water to the rudder.

In order that the ship should steer well, and quickly answer her helm, the wing-transom must not be placed too low, nor the fashion-pieces too full below the load-water line; and the narrowing of the floor, or half-breadth of the rising, not continued too full towards aft, but that the water-lines, as they approach the stern-post, may taper handsomely into the same, so that every succeeding water-line, as they approach nearer the keel, may have their curvature more delicate, as may be seen by referring to the half breadth plan in *Plate 1.* It is also evident, that the prompt effect of the rudder must depend in a great measure on the *cleanness* of the ship's run, so that the fluid shall have an unimpeded passage to it, whereby its inclination shall have the greatest effort from the water.

That a ship may carry her guns well above the water, a long floor timber will be necessary, and not much rising; the midship-frame should be very full, upper futtocks nearly straight, upper works very light, and kept as low as possible, and the wing-transom not placed too high.

To make a ship carry her guns well above water, carry much sail, be a fast sailer, and likewise steer well, are four such rare qualities, as are hardly to be united in the same vessel, because it would require a very full bottom and great breadth to gain the two former qualities, and less breadth and a sharp or clean bottom to gain the latter; but if we consider that a full ship will carry more sail than a sharp one, we may perceive the possibility of so constructing the body, as to possess these qualities, and they may be so united, that each of them may be discerned in some degree of eminence, for it is not possible that all of them can be united in one body to a degree of perfection; we must, therefore, while we retain a portion of each, give the superiority to that which is most consistent with the purposes for which the vessel is peculiarly designed.

Hence it is plain, that judiciously placing the midship-bend is of the utmost consequence in the construction of ships' bodies; and its being placed nearer forward, will, consequently, make the fore-body more full, and will best answer every purpose, especially that of velocity; and although it is plain, that by so doing the entrance of the ship will be more full, and present apparently more absolute force against the resisting medium, than when the midship-bend is placed nearer to the middle of the ship's length, yet by placing it more forward, the body will decline horizontally so much the quicker, and part of the effect of that resistance, caused by the lateral pressure of the water, will be lessened, which must certainly be of more service to the velocity, than what is lost by making the fore-part of the ship somewhat fuller, and this seems to promise the connection of capacity with velocity, the two great objects to be pursued in the formation of ships' bodies under water. In addition to this, by carrying the midship-bend forward, a ship will steer better, and the rudder have the more command to bear up the ship in a gale of wind; for when a ship is under a press of sail, the water is forced up at the bow above the horizontal, and the bow likewise pressed down, which amounts to nearly the same, with respect to her helm, as if the ship was trimmed by the head; again, ships that carry their helm amidships in light winds, require it more a-weather when the wind blows.

After all that has been written concerning the placing of the midship-bend, all agree to place it before the middle of the length, or about five-twelfths of the length abaft the foremast-perpendicular; but in *Plate 1.* which ship has stood the test of experiment, it was placed at 69 feet abaft the foremast-perpendicular, consequently this is the broadest part of the ship, called the midships, or dead-flat, known by this character  $\oplus$ , and where all the heights in midships are set up. From  $\oplus$  the stations of all the timbers may be set off; but it will only be necessary to square up a perpendicular at the joint of every frame-timber, their distance being double that of the room and space, which in *Plate 1.* is two feet nine inches.

The dead-flat in *Plate 1.* is a single timber, and the perpendicular, marked  $\oplus$ , the middle of it: therefore, for the joints of the annexed frames let off before  $\oplus$ , two feet nine inches for the joint of (A), and two feet nine inches abaft  $\oplus$  for the joint of (1), square up perpendiculars from the upper edge of the keel; then from (A) continue letting off five feet six inches for the joints of frame B, C, D, to X, in the fore-body, and the same distance abaft (1) for the joints of

## SHIP-BUILDING.

frame (3), 2, 4, 6, to 36 in the after-body, as shewn in *Plate I*. Now  $\oplus$ , (A), (1), (2), and (3), are called flats, as they are the timbers which are placed in the flat part of the ship amidships, have no bevellings, and consequently do not partake of the rising.

The lower height of breadth is an imaginary line, not only to assist in the construction of the body, but a line confining the greatest breadths in the ship, all fore and aft, and should next be determined upon. Its height at  $\oplus$  is 21 feet 3 inches above the upper edge of the keel; and that the said height of breadth should be higher afore and abaft is only reasonable as a reserve, to be a support to the vessel when heeling by the pressure of the wind upon the sails; for when a ship is close-hauled by the wind, and lies much over, the weather-side would lose much of the breadth, whereas, on the contrary, the lee-side would then gain considerably, and meeting with a greater resistance, be enabled to carry the greater sail; therefore forward at the rabbet of the stem its height is 29 feet, and abaft at the counter-timber 29 feet 6 inches; and all the heights between should form a fair curve, like the ticked line in the sheer-draught, *Plate I*.

It may here be remarked, that flat-floored ships do not require their height of breadth to be raised so high forward and aft, for by their construction they are stiffer under sail, and carry their weight of cargo low down.

The body below the lower height of breadth may now be formed, as the frames or bends, when put together, and the joint placed to the fore-mentioned perpendiculars, the sides of every port will be formed so as to cut none of the principal timbers, and are so disposed as to weaken the ship as little as possible. Now as capacity, velocity, &c. depend upon the figure of the immersed part of the body, and because the properties which every ship ought to possess are, in a manner, subversive of, or in opposition to, each other, as before observed, the great art certainly is so to form the body, that none of the desired qualities shall be omitted, giving, at the same time, preference to that which is most required. In ships of war, capacity, stability, velocity, and strength, are essentially necessary; the first and second we shall endeavour to prove by calculations hereafter; the third may be affirmed, as the vessel was actually built, and answered that purpose; and the last is now so well established in the British navy as to need little addition.

The half-breadth plan must be next drawn: thus, draw a straight line below the sheer-plan, as in *Plate I*, the whole length of the ship, and parallel to the upper edge of the keel, which line will represent the middle line of the ship, at any height passing fore and aft, or lengthwise; observing to keep the said middle line sufficiently below the scale, so as to admit of the main half-breadth line coming clear of it.

Then square down from the sheer-plan all the perpendiculars or joints of the frame-timbers, to the middle line of the half-breadth plan, and likewise the foremost and after-perpendicular. The main half-breadth line may now be drawn, by setting-off from the middle line in the plan the following half-breadths at each respective timber; thus, at  $\oplus$ , 24 feet; at F, 23 feet 11 $\frac{1}{2}$  inches; at H, 23 feet 11 inches; at K, 23 feet 10 inches; at M, 23 feet 5 $\frac{1}{2}$  inches; at O, 23 feet; at Q, 22 feet 2 inches; at S, 20 feet 4 inches; at U, 17 feet 6 inches; at X, 12 feet 6 inches; and to end this line at the fore part, let the height of the breadth-line in the sheer-plan, where it intersects the aft-side of the rabbet at the stem, be squared down to the middle line in the half-breadth plan, and likewise the fore part of the stem: upon the lines last squared down, set off the half-siding of the stem from

the middle line and parallel thereto, which is ten inches; then, with compasses, take the thickness of the bottom plank, which is four inches, and describe the rabbet of the stem by the triangle shewn in the half-breadth plan; from thence a fair curve line drawn through the half-breadths set off, forms the half-breadth line to  $\oplus$ . In the same manner set off the half-breadths abaft  $\oplus$ , and draw in the remainder of the half-breadth line, as the ending of it abaft will be described hereafter.

Observe, the various curves represented on the several plans used in ship-building, except where they are segments of circles, such as the fore part of the main half-breadth, &c. are drawn by small pliable battens confined thereto by weights, or by thin moulds made of pear tree veneers, whose edges are made to geometrical curves of all kinds.

Now the main half-breadth line being drawn, we have a half section of the ship lengthwise at the broadest place, that is at the height, and in the direction of the lower height of breadth line in the sheer-plan, *Plate I*.

The immersed part, or body of the ship under water, must be next formed, and the capacity of the vessel ascertained, before the upper works, or that above the water, need come under consideration; it is therefore necessary to describe in what manner the several forms of ships' bodies are to be constructed. In the royal navy, the midship parts of the body of ships are formed by segments of circles called sweeps; such are the lower and upper breadth-sweeps, floor-sweep, and reconciling-sweep, their several centres being given by lines, except the reconciling-sweep, whose centre is without the limits of the draught. The lower-breadth and floor-sweeps are joined by the reconciling-sweep, and make a fair curve from the lower height of breadth to the rising-line, by which the floor-sweep is governed; then, by drawing a straight or curving line from the upper edge of the rabbet of the keel to touch the back of the floor-sweep, the form of the midship part of the body below the lower height of breadth will be complete.

Observe, the floor-sweep forms the body at the floor-heads, particularly along the midship part of the body, and is limited by an horizontal line above the keel in the body-plan, and its distance above the keel at the midship-timber is called the dead-rising. The rising of the floor in the sheer-plan is a curve line intersecting the dead-rising at the midships; and in flat-floored, or burthenfome ships, it continues nearly parallel with the keel for some distance afore and abaft the midship-timber; and all the timbers, where the rising is parallel with the keel, are called flats, as before observed. The rising-line, which governs the floor-sweeps, is not the least interesting of the series, because it exhibits, on many points, general deductions, and tends to establish theories which may serve to direct future observations; and the method of constructing the midship-floors of ships, where velocity is preferred, by lengthening the radii of the floor-sweep forward and aft, is preferable to the rising-line, as used in constructing merchant-ships for burden, where the radii of the floor-sweeps all fore and aft are of the same length as at the midship-timber; because by the former method, every floor-timber from the dead-flat is graduated by a larger circle. By the latter method, not only the construction, but the laying-off the ship is facilitated, because in any ship constructed by the same length of radii, we may venture, so far as the rising-line is continued, not only to form all the lower part of the ship on the draught, but also on the mould-loft-floor, without running any ribband or horizontal lines till that part is finished. Again, this method affords a greater assistance, as by it the floors may be constructed all fore and aft; but the floors near the midships only can be constructed,

constructed, when the radii of the floor-sweeps alter much in their length.

Neither the rising-line in the sheer-plan, nor the half-breadth of the rising, would continue to be the curves as first constructed, if the form of the body first designed were to be altered in that part. It is evident, then, that the rising-line may be drawn according to the judgment of the artist in the construction of any draught, observing to make it a fair elliptical curve, (for much depends on the construction of the lower part of the body,) by judiciously narrowing the floor-sweep, or half-breadth of the rising; for the more parallel it is kept with the middle line, the less will be the velocity of the ship. Again, the quicker this curve is, the less bearing will the ship have; and though it may be supposed, when the rising-line is formed in the sheer-plan, and likewise its half-breadth, it is reasonable to expect a fair body, yet we cannot be certain of its producing that form of body which is really intended agreeable to the use which the ship is designed for, unless by frequently designing of bodies we can form an exact idea before we proceed. Therefore the young artist should improve himself by drawing bodies constructed by the rising-line of ships of different properties, till he forms in his own judgment a perfect idea of this mode of construction. For instance, if it be required to make the ship cleaner, lift the rising-line in the sheer-plan, and narrow its half-breadth; and where it may be required to make the ship fuller, lower the rising-line in the sheer-plan, and increase its half-breadth; which sufficiently proves that the rising-line is as variable as the different forms of ships' bodies may require. See for fulness the plate of the East India ship, the plate of the 74-gun ship, which is sharper, and also the frigate of 40 guns, which is sharper still; and we shall then find it a very complete method of constructing the lower parts of such ships fair, particularly those that require some provision or fulness of body to assist them in taking the ground. The further forward and aft the body is assisted by the rising-line, the more merit there will be in the construction, and the greater certainty of producing a fair body: notwithstanding all this, some bodies are constructed without any floor-sweeps, which must be the case in very sharp bodies, such as cutters, &c.

It may be further observed, that the rising-line cannot, from its nature, be formed by any regular proportional method, from which there can be no variation without impropriety; nor can it be constructed to any fixed proportion, unless ships of different classes were built exactly similar to each other, because the rising-line in ships of war, and those which are constructed for velocity, though suitable to the construction of the lower part of each ship, and likely to answer the purpose for which they are designed, cannot be equally proper for ships of the same length and breadth, if required chiefly for burden; as in the last case not only the form of the midship-bend, but every part of the bottom must be differently formed, which will be clearly seen by examining the plates of the 74 and 40-gun ships, and the plate of the East India ship, which was found to answer admirably well.

Whole-moulding was formerly a method of constructing the immersed part of ships' bodies, by the mould being made to the form of the midship-bend, which, with the addition of the floor-hollow, would mould all the timbers below the main-breadth in the square body. But since the art of ship-building has arrived to its present perfection, the method of whole-moulding, for the following reasons, has been justly laid aside. For by whole-moulding, no more is narrowed at the floor than at the main-breadth, that is to say, the curves of each are kept parallel; nor must the rising-line in the

sheer-plan lift any more than the lower height of breadth; which, according to the form of some midship-bends, would make a very ill-constructed body; for by continuing that nearly forward and aft, the ship would not only be incapable of rising in a heavy sea, but be deprived in a great measure of the more advantageous use of her rudder. Nevertheless this method is still continued in the formation of boats.

Proceed now to draw the plan of projection, or body-plan, thus: continue the line at the upper edge of the keel beyond the after-end of the sheer-plan, as in *Plate I.*, and square up a perpendicular for the side-line of the fore-body, observing to keep it clear of the stern; from that perpendicular set off 48 feet, the ship's main breadth at dead-flat, and square up another perpendicular for the side-line of the after-body, and equally between both square up another perpendicular, which is the middle line to both bodies respectively; then the line prolonged from the upper edge of the keel is the base line of the body-plan. Draw in the horizontal lines, as may be seen in the body-plan, *Plate I.* at the lower heights of breadth, by transferring their heights from the sheer-plan at the several frame-timbers: those before the dead-flat, set up in the body-plan to the right of the middle line, which are to represent the fore-body, and those heights abaft dead-flat, to the left hand for the after-body. Then from the half-breadth plan take the main half-breadth of each frame, and set it off from the middle line in the body-plan, upon its corresponding height of breadth-line; and from thence set off towards the middle line the length of their respective lower-breadth sweeps: thus, to describe the midship-timber, or dead-flat, extend the compasses to 18 feet 6 inches, the radii of lower-breadth sweeps at dead-flat, and draw part of a circle downwards, intersecting its main breadth at its horizontal height.

Then the centre heights of the floor-sweeps in the body-plan must be taken from the curve-line representing their heights in the sheer-plan, which at dead-flat will be found to intersect the upper edge of the keel; but in the body-plan, its height at dead-flat is 11 feet 6 inches, and there an horizontal line is drawn to the distance of the centre, or its half-breadth from the middle line, and all the heights of centres are respectively set upwards above this line, on perpendiculars squared upwards at the half-breadth of the centre of each floor-sweep of its corresponding frame or timber, as taken from the half-breadth plan; and the reason for not keeping the said curve-line or heights in the sheer-plan as in the body-plan, is because it would interfere with the curve-lines above. Now by inspecting *Plate I.* it will be readily seen, that by raising the heights of those centres in the sheer-plan, consequently in the body-plan, and by narrowing their half-breadths in the half-breadth plan, their centres would be brought nearer the middle line in the body-plan, the floor-rising would become quicker, and the ship have less bearing, and *vice versa*, more full and burthenome; thus must the rising and narrowing of the centres be adjusted till the body of the vessel has the capacity required for whatever service she may be designed.

But as in this mode of construction the centres only, and not the length of the floor-sweeps, are given, a diagonal ribband must be drawn in the half-breadth plan, as in *Plate I.*, by setting off from the middle line at A, 16 feet; at B, 15 feet 9 inches; at D, 15 feet 5 inches; at E, 15 feet 1 inch; at H, 14 feet 7 inches; at K, 14 feet; at M, 13 feet  $\frac{1}{2}$  an inch; at O, 11 feet 11 inches; at Q, 10 feet 3 inches; at S, 8 feet 6 inches; at U, 6 feet 1 inch; and at X, 2 feet 5 inches. Then in the after-body set off at 2, 15 feet 11  $\frac{1}{2}$  inches; at 3, 15 feet 10  $\frac{1}{2}$  inches; at 6, 15 feet 9 inches; at 8, 15 feet 6 inches; at 10, 15 feet 4 inches; at 12, 15 feet 1 inch; at 14,

## SHIP-BUILDING.

14 feet 11 inches; at 16, 14 feet 5 inches; at 18, 14 feet; at 20, 13 feet  $3\frac{1}{2}$  inches; at 22, 12 feet 5 inches; at 24, 11 feet 7 inches; at 26, 10 feet 5 inches; at 28, 9 feet 1 inch; at 30, 6 feet 7 inches; at 32, 5 feet 10 inches; at 34, 4 feet; and at 36, 2 feet.

Now to end this diagonal, it must be drawn in the body-plan thus; set up the middle line from the base 12 feet 2 inches, and on the base, from each side of the middle line, 11 feet 9 inches, then draw the diagonal ticked line, as shewn in *Plate I*. In draughts, diagonal lines are distinguished by red ink. Then in the body-plan draw the half-fiding of the stem in the fore-body, and the half-fiding of the stern-post in the after-body: for the latter set up 26 feet above the base, and at that height set off from the middle line 10 inches in the half-fiding of the post at the head, and 9 inches in the fore-body, the half-fiding of the stem at that height; and on the base line  $7\frac{1}{2}$  inches from each side the middle line, the half-fiding of post and stem at the heel; then draw straight lines to each spot set off, and the half-fiding of the stern-post and stem will be represented in the body-plan. Now to complete or end the diagonal line on the half-breadth plan, its height or intersection at the post and stem must be taken in the body-plan, and transferred respectively to the fore-side of the rabbet of the stem, and aft-side of the rabbet of the post in the sheer-plan, and from thence let them be squared down to the middle line of the half-breadth plan; then take with compasses the half thickness of the post and stem in the body-plan, in the direction of the said diagonal line, and set them off respectively from the middle line in the half-breadth plan, on the lines last squared down; and from the intersection as a centre, sweep an arc towards the midships, with compasses opened to the thickness of the rabbet taken diagonally; then a fair curve drawn through all the spots as above set off, touching the back of the arcs, will form the diagonal line at the floor-heads, as shewn in the half-breadth plan, *Plate I*.

Now may the timbers, as far as the floor-sweeps are useful, be completed in the body-plan below the lower height of breadth, beginning at dead-flat: thus, take the half-breadth of the floor diagonal at  $\oplus$  in the half-breadth plan, and set it down the diagonal from the middle line in the body-plan; then take the half-breadth of the floor-sweeps in like manner, and set it off from the middle line in the body-plan on the horizontal line before drawn at its height, and from the intersection extend the compasses to the half-breadth of the floor diagonal, and sweep an arc upwards from the dead-rising, which is six inches at  $\oplus$ ; then with the reconciling-sweep, which is of a long radius compared with the others, unite the lower-breadth sweep and floor-sweep together; for the more the midship-frames deviate from the segment of a circle, the less will be the rolling motion of the ship; unite the floor-sweep with the upper edge of the rabbet of the keel with a curve or straight line, and the midship-timber will be formed below the lower breadth. In the same manner may be formed the frame-timbers B, D, F, H, and K, in the fore-body, and 2, 4, 6, 8, 10, to 24 in the after-body, by setting off the half-breadth of each frame's diagonal as at  $\oplus$ , their corresponding heights of breadths, main half-breadths, and centres of each sweep, as before directed, and by reconciling the lower-breadth sweeps and floor-sweeps together, and ending them into the rabbet at the keel; thus the midship part of the body will be formed from K forward to 24 abaft.

Hence it may be readily conceived, that bodies full or sharp, either for burthen or velocity, may be constructed by altering the radii of the different sweeps; and unless bodies of ships could be constructed from some geometrical

figure, a more certain method than the above cannot be given.

The body being thus far formed, that is from K forward to 24 abaft, proceed to prove it by horizontal lines, and finish the remaining part forward and aft. These lines are generally called water-lines, as the ship's bottom at the surface of the water, supposing the keel kept parallel thereto, would be of the same figure as those lines represented in the half-breadth plan, with the addition of the thickness of the bottom plank in that direction. The upper one is called the load-water-line, or line of floatation, when the vessel is supposed fit for sea, which will be treated of more particularly hereafter; the other water-lines may be equally divided between the upper or load-water-line, and upper edge of the keel or rabbet. Although a ship may draw more water abaft than forward for her best sailing trim, yet to keep the several water-lines horizontal, or parallel with the upper edge of the keel, is the most useful in construction; and the water-lines, as represented in the half-breadth plan, form curves, limiting the various half-breadths of the ship at the heights of their corresponding lines in the body-plan. They are generally drawn with green ink, but in *Plate I* with corresponding dotted lines, and are represented by straight lines in the sheer-plan; and if parallel with the keel they will be horizontal lines in the body-plan, but if the vessel is to be constructed to draw much more water aft than forward, the water-lines will not of course be parallel with the upper edge of the keel; then, owing to their various heights at each timber in the sheer-plan, they will form curves at those heights in the body-plan, and the more they vary from an horizontal line, the less accurate will the limits of their half-breadths be described in the half-breadth plan.

In *Plate I* the upper horizontal water-line is 20 feet above the lower edge of the keel; and between that and the upper edge of the rabbet of the keel, are equally divided four more water-lines, as in the sheer-plan. The water-lines may now be drawn in the half-breadth plan from the body-plan, as far as the timbers are there formed; thus, continue the water-lines aft from the sheer-plan across the body-plan, then take off with compasses, or a slip of paper and pencil, their various half-breadths from the middle line, to the places where the several timbers intersect each water-line, and set them off on their corresponding timbers from the middle line in the half-breadth plan; then to end each water-line square down where they intersect the fore-part of the rabbet at the stem, and aft-part of the rabbet at the stern-post in the sheer-plan to the middle line of the half-breadth plan; then take the half-fiding of the stem and the stern-post at each water-line from the middle line in the body-plan, and set them respectively on the lines last squared down from the middle line in the half-breadth plan; from thence, as the centre, with compasses opened to the thickness of the bottom plank, make a sweep, the back of which is the ending of the line. Then complete the fore and after ends of each water-line with curves, as in the half-breadth plan, avoiding all inflected curves or hollow water-lines at the fore part, as they may be drawn by arcs of circles, although their centres may be without the limits of the plates of ship-building.

Now the whole of the body may be completed under the lower height of breadth, observing to sweep each timber below its height of breadth, as before directed; then by taking off the half-breadth of each timber, where they intersect the water-lines from the middle line in the half-breadth plan, and setting them off on their corresponding water-lines from the middle line in the body-plan, curves passing through those spots will shape the timber; but to end them into the rabbet, or complete the heeling, the keel must

## SHIP-BUILDING.

must be drawn in the body-plan; thus, set off nine inches on the base line from each side of the middle line, being the half-siding of the keel, and also 18 inches below the base line, which squared will represent the thwartship section of the keel in midships; then, with compasses opened to the thickness of the bottom plank, fix one leg where the keel intersects the base line, which is the upper side of the rabbet, and sweep an arc within the keel to intersect the side, and from that intersection sweep another arc upwards; then a triangle drawn within those arcs, represents the rabbet of the keel in midships, and all the timbers along the midships, until the rabbet opens, end where the rabbet intersects the base line; but when the rabbet opens by the timbers rising forward and aft, they will end over the back of the sweep to the inner edge of the rabbet. The timbers near the after-end of the keel must be ended agreeably to the tapering of the keel, which tapers in the siding from frame 24 to 15 inches at the after-end: this must be set off from the middle line in the half-breadth plan, and the half-siding of the keel taken at each timber, and set off on the upper edge of the keel from the middle line in the body-plan; then set within the half-siding of the keel the thickness of the bottom plank, and that ends the timber. But as the frames in the fore-body before O heel upon the stem, their heights must be taken in the sheer-plan, where they intersect the lower part of the rabbet, and those heights set up in the body-plan upon the half-thickness of the stem; then with compasses opened to the thickness of the bottom plank, fix one leg in the heights last set off, and sweep a circle within the siding, and the heel passes over the back of the circle, and the rabbet completed by a square applied to the line of the timber, so as to intersect the height set up, as shewn in the plan of the fore-body, *Plate I*.

Now, as a further proof of the correctness of the after-body, draw four or five perpendicular sections, or, as they are commonly called, buttock-lines; but first prove the heels of the after-timbers by the bearding-line, thus; represent the half-thickness of the dead or rising wood in the body-plan, by drawing a perpendicular from the base line to the head of the stern-post. Then from the base line take the heights where the after-timbers cross the half-thickness of the dead wood, and set them up from the upper edge of the rabbet on their corresponding timbers in the sheer-plan; then draw a curve through those heights, to break in fair with the fore-side of the rabbet on the stern-post, and this curve will represent the bearding-line in the sheer-plan, and limits the heels of the after-timbers, as far as they cut off or lay against the dead-wood.

The heels of the timbers being found to agree with the bearding-line, from the fairness of its curve (observe, the term *fair*, so often used in the delineation of the several plans of a ship, signifies that the variety of curved lines therein used have no inequalities in them, but are even as a circle struck from its centre, as most of the lines in the formation of ships' bodies are curves, but many of their centres are too distant for application; and the fairness required is, that where every different curve unites no angle may be discoverable), proceed to prove the after-timbers by the buttock-lines; thus, square up from the base line in the after-body plan five perpendiculars, equally divided between the outside of the wing-transom, and the half-thickness of the dead-wood; that is, the outer buttock-line at 15 feet 10 inches, and the intermediate four at 3 feet 2 inches asunder.

Then take the heights at the first buttock-line, or that next the post, at the intersection of each timber from the base line in the after-body, and set them up from the upper edge of the rabbet on the corresponding timbers in the sheer-

plan; and to end the buttock-lines, the upper side of the wing-transom and margin-line must be drawn in the several plans; thus, set up 26 feet 10 inches for the height of the upper side of the wing-transom in the sheer and body-plans, drawing a horizontal line at the stern-post and across the body-plan; then from the middle line set off 16 feet 6 inches, the half-breadth of the wing-transom, and at that place set down, below the upper side of the wing-transom, six inches, and sweep the arc, whose centre will be in the middle line; and the round-up of the upper side of the wing-transom will be represented as in the body-plan, *Plate I*; from the same centre sweep another arc six inches below the upper side of the wing-transom, which is called the margin-line. Then, in the half-breadth plan, sweep in the round aft or aft-side of the wing-transom; thus, square down from the sheer-plan the fore-side of the rabbet of the stern-post, where it cuts the upper side of the wing-transom, to the half-breadth plan, and upon the line so squared down, set off the half-breadth of the wing-transom from the middle line, and at that place set forward seven inches, and sweep the arc representing the round aft of the wing-transom, the centre of which is in the middle line.

Draw an horizontal line at six inches below the upper side of the wing-transom in the sheer-plan, and upon it square up the round forward of the wing-transom from the half-breadth plan; and from thence draw a line to the upper side of the wing-transom at the rabbet of the post, and the upper side of the wing-transom will be shewn, both to its round down and forward in the sheer-plan. Transfer the height of the margin-line from the body to the sheer-plan, and there draw a line parallel to the upper side of the wing-transom last drawn, and unite them at the fore part of the wing-transom by a line parallel to the rabbet of the post. The margin-line must next be shewn in the half-breadth plan, by squaring it down from the sheer-plan, and making it a parallel curve to the aft-side of the wing-transom; the distance, however small, being equal to the rake of the rabbet of the post, in the depth of the margin at the aft-side of the wing-transom. The margin-line being drawn in every plan of *Plate I*, proceed to end the buttock-lines in the sheer-plan; thus, take the distance of the buttock-lines square from the middle line of the body-plan, and set them off the same from the middle line in the half-breadth plan, drawing lines parallel thereto from the aft-side of the wing-transom to the after square timber, which will represent the buttock-lines in the half-breadth plan: then, where those lines intersect the margin-line in the half-breadth plan, square up spots to the margin-line in the sheer-plan, which spots will give the true ending of the buttock-lines, also square up the intersection of the buttock-lines with the water-lines from the half-breadth to the sheer plan; then transfer all the heights of the buttock-lines, where the timbers cross them in the body-plan, to the sheer-plan, as before directed, and draw fair curves through all the spots set off to the endings, and the after part of the ship will be represented in the sheer-plan, as cut by those perpendicular sections, as in *Plate I*.

Now if the buttock-lines make fair curves, the after-timbers will be proved correct, and likewise the water lines abate in the half-breadth plan; but if the buttock-lines to be made fair curves deviate from the spots as set off, then must the timbers be altered accordingly, and consequently the water-lines. But as a further proof as to the correctness of the buttock, or that part of the body close aft, square up one or two imaginary or proof timbers, equally between the after frame-timber 37 and the wing-transom at the side, as represented by the ticked lines in the sheer-plan, *Plate I*. Then take the heights on a perpendicular from the upper edge of the keel in the sheer-plan, where the

proof.

proof-timbers intersect the buttock-lines and bearding-line, and transfer them to the body-plan above the base line upon each corresponding buttock-line, and half-thickness of the dead-wood; take also the half-breadth of the proof-timbers where they intersect the water-lines in the half-breadth plan, and transfer them to their respective water-lines in the body-plan; but though the proof-timbers cross the stern-post, their heels may be set off, as before directed for the after-timbers; then if the spots so set off produce fair curves, as the ticked timber shewn in the body-plan, *Plate I.*, we may conclude that the after-body is sufficiently proved and its fairness accurate. The fore-body may be proved by vertical sections, in a similar manner as described above, only their ending will be determined by squaring up their intersections with the main-breadth line, from the half-breadth plan to the sheer-plan.

Having completed the form of the body thus far, it will be necessary to ascertain the capacity and stability of the part immersed, as in all ships of war there is a fixed height for the lower fill of the midship port above the load-water-line, allowing for six months' stores, provisions, &c. to be on board; and the capacity should be simply adequate for this purpose; for the nearer this is approached unto, the more merit is due to the contractor: it should not be more, to avoid superfluous expence in the building, and the additional men required to navigate her; nor should it be less, from an obvious general insufficiency to answer the required purposes: the bias should rather lead to increase than diminish in capacity. In ships for commerce, an exact estimation of their capacity is more frequently required to regulate the port duties, and the contracts between merchant owners and builders, than to insure their stability, a fixed line of floatation, and fast sailing, as the charge may be regulated by their ability to support it, and their load-water-line may be considerably varied, without any hurtful interference with other essential qualities.

Let us at present suppose the 74-gun ship, *Plate I.* as floating upon the water in equilibrium, and the upper water-line upon a level with the surface of the water, by which the ship is divided into two parts, the one above and the other under the water, which we call the immersed part of the body. In order to judge of this state of equilibrium, in which we suppose the vessel to be, it is necessary to take into consideration all the forces which act upon the vessel: and first the weight of the whole vessel presents itself, by which it is pressed down vertically in a line passing through the centre of gravity of the vessel. This force must therefore be counterbalanced by all the efforts which the water exerts upon the surface of the immersed part, and consequently it will be necessary to determine the pressure that each particle of the immersed surface sustains from the water, which requires researches very embarrassing, and a long series of calculations: but the following considerations will easily lead us to the desired end.

As the vessel occupies in the water, by its immersed part, the cavity formed by the body under the upper water-line, let us compare this case with another, the above cavity being filled with water: it is at first evident, that this mass of water will be in a perfect equilibrium with the water that surrounds it; and it is also plain, that this mass sustains from the part of the surrounding water, the same efforts which the vessel suffers from it. From whence we see, that these efforts of the water balance the weight of the mass of water which we have just substituted in the place of the vessel. Therefore, since these same efforts sustain also the weight of the whole vessel, it follows that this weight is precisely equal to the weight of the mass of water which fills the same cavity as formed by the body of the vessel

under the upper water-line: or rather, whose volume is equal to the volume of the immersed part of the vessel.

Here, therefore, is the first great principle upon which is founded the theory of the floating of bodies that swim upon the water. It is, that the immersed part must always be equal in volume to a mass of water, which would have the same weight as that of the vessel: and it is from this principle that we determine the true weight of a vessel, by measuring the volume of its immersed part in the water; for then, by reckoning 64,375 lbs. avoirdupois for each cubic foot, we shall find the weight of the vessel expressed in pounds.

However, this principle, only, is not sufficient to determine the state of the equilibrium of the vessel; another must be still joined to it, and which we shall find with the same facility. We have only to consider in *Plate I.* the centre of gravity of the mass of water under the upper water-line; then we shall easily conceive that all the efforts of the surrounding water are in equilibrium with a force equal to the weight of the mass of water displaced by the bottom under the upper water-line, which should act in a perpendicular direction through the centre of gravity of the said mass of water downwards: therefore, in order that the vessel may be in equilibrium with the same efforts, it is necessary that the centre of gravity of the vessel be in the same vertical line in which the centre of gravity of the immersed part is found. For that purpose we have only to mark within the vessel the very point where the centre of gravity of the immersed part would be, if it was composed of an homogeneous matter, and this point we shall term the centre of cavity.

Now the state of the equilibrium of any vessel will be determined from these two principles: 1st, that the immersed part must be equal in volume to a mass of water, whose weight would be equal to that of the vessel; and, 2dly, that the centre of gravity of the vessel, and the centre of cavity, fall in the same vertical line, which is the vertical axis of the vessel. With respect to the centre of cavity, it is evident that it must always fall below the load-water-line; and if the immersed part should preserve, in descending, every where the same surface, or that it had either a prismatic or cylindrical figure, then the centre of cavity would fall in the middle of the vertical axis between the load-water-line and the keel. But if the extent diminished uniformly from the load-water-line to the keel, and it at last terminated in a right line drawn through the keel, equal and parallel to the load-water-line, then the elevation of the centre of cavity would be two-thirds of the immersed part above the keel; and if the same immersed part should terminate in a point at the keel as a pyramid reversed, then the centre of cavity would be three-fourths of the immersed part above the keel; but with respect to the centre of gravity of the vessel, it may fall either above or below the load-water-line, according as the lading should be distributed throughout the body of the vessel. Thus in *Plate I.* of ships of war in general, where the guns constitute a considerable part of the weight, since they are placed above the water, the centre of gravity will be situated above its surface.

The bottoms, or immersed parts of vessels in general not strictly agreeing with any of the above-mentioned geometrical forms, it will be necessary to gauge the form of the immersed part of the vessel's bottom, or, which is the same thing, the quantity of water displaced by the bottom; the weight of which, as before observed, is equal to the weight of the ship, its rigging, provisions, and every thing on board. If, therefore, the exact weight of the ship when ready for sea be calculated, and also the number of cubic feet of water displaced by the ship's bottom below the load-water-line, it will then be known if the load-water-line is properly placed

## SHIP-BUILDING.

placed on the draught. However operose and difficult the calculations necessary to ascertain the capacity, itability, &c. of ships may be, it must be allowed that it will require the utmost care in the execution, to find the exact dimensions of the several sections of the ship from the draught, (especially as every dimension in the ship is forty-eight times bigger than their similar ones on the draught, supposing it to be drawn by a quarter of an inch scale to a foot), as an error of a quarter of an inch in the draught, which is only the forty-eighth part of a real inch in the ship, will occasion an error of 110,592 cubic quarters of an inch in the ship,

provided the error be in all the three dimensions, viz. length, breadth, and depth. Great precision, indeed, must be used to measure to a quarter of an inch in *Plate I*, seeing it is only drawn, for convenience, to an eighth of an inch scale. But as these calculations cannot be made with too great an exactness, the body had better be expanded on the mould-loft floor to the full size, and then the various dimensions may be taken very accurately.

The estimated weight of a 74-gun ship, as fitted for sea, with six months' provisions on board, is given in the following table.

An Estimate of the Weight of the 74-Gun Ship, *Plate I*, as fitted for Sea, with Six Months' Provisions, Guns, &c.

	Feet.	Tons.	Pounds.
<b>Weight of the Hull.</b>			
Oak timber, at 57.8125 lbs. to the cubical foot	47859	1236	208
Elm timber, at 37.5 to the cubical foot	462	7	1645
Fir timber, at 34.25 to the cubical foot	4397	67	517
Copper bolts, rudder, braces, &c. &c.		20	1748
Iron knees, bolts, nails, &c. &c.		28	2070
Lead-work		2	160

The furniture		192	312
Guns and ammunition		211	1427
Officers' stores		21	560
Men and ballast		395	
Provisions		600	
<b>Total weight</b>		<b>2810</b>	<b>745</b>

# SHIP-BUILDING.

By the preceding estimate, we find the 74-gun ship, *Pl. I.* weighs, when brought down to her load-water-line, 2810 tons 745 pounds, that is to say, when fitted for sea, with six months' provisions on board. It may now be known, with some degree of certainty, if the upper water-line on the sheer-draught, *Plate I.*, be properly placed, only by reducing the immerfed part of the bottom into cubic feet; for, if the 74-gun ship, when brought down to the load-water-line, weighs 2810 tons 745 pounds, the quantity of water displaced must also be 2810 tons 745 pounds, or 6,295,145 pounds. Now a cubic foot of salt-water being supposed to weigh 64,375 pounds, we shall therefore find, that if we divide 6,295,145 by 64,375, the quotient will be 97,788 solid feet, which is the contents of that volume of water which she must displace corresponding to her weight.

### *Displacement or Capacity.*

The solid contents of a ship's bottom, were it any regular figure, might be easily calculated geometrically; but as its curves are so various, the following rule, by approximation, may be near enough for practice.

Take the half-breadths of every other frame, and double them, from 26 to O, in the half-breadth plan upon the upper water-line; then find the sum of these, together with half the foremost frame O, and aftermost frame 26. Now, the frames being equidistant, multiply that sum by 11 feet, the distance between every other frame, and the product is the area of the water-line contained between the frames 26 and O; then find the area of that part of the water-line afore O, and abaft 26, by taking the half-breadth of every timber, and proceed as before, and multiply by 2 feet 9 inches; find also the area of the stem, knee, and gripe, before the foremost-timber, also the area of the stern-post and rudder abaft the after-timber; then these areas being added to the first found, will be the area of the surface of the whole water-line. Note, the thickness of the bottom plank, as taken in that direction, must be added.

The areas of the other water-lines may be found in the same manner: then the sum of all these areas, except the uppermost and lowermost, of which only one-half of each must be taken, being multiplied by 3.6 feet, the distance between the water-lines (these lines in the sheer-plan being also equidistant from each other), and the product will be the solid content of the space contained between the lower and upper water-lines.

Add the area of the lower water-line to the area of the upper side of the keel; multiply half that sum by the distance between them, the product will be the solid content of that part between the lower water-line and upper edge of the keel.

The solid contents of the keel must be next found, by multiplying the area by its depth; then the sum of these solid contents will be the number of cubic feet contained in the immerfed part of the bottom, below the upper water-line.

The reason of the above rule will be obvious, by referring to the article *STEREOMETRY*; for there, to find the solid contents of any irregular body, the area of the surfaces must be taken by ordinates (and such are the joints of the frames of a ship), and those surfaces multiplied by the depth or depths (and such are the water-lines), which give the solid contents required.

The application of this rule, in finding the cubic feet contained in the bottom of the 74-gun ship, below the upper water-line in *Plate I.*

Area

# SHIP-BUILDING.

## Area of the Upper Side of the Keel.

## *Method of finding the Centre of Displacement or Support.*

The centre of gravity of a ship, supposed homogeneous, and in a state of equilibrium, is in a perpendicular section, passing through the keel, and dividing the ship into two equal and similar parts, at a certain distance from the stern and altitude above the keel.

To ascertain the centre of displacement, or centre of gravity, of the immersed part of a ship's bottom, in a state of equilibrium, begin by determining the centre of gravity of the upper horizontal section, or water-line; and as the two sides are equal and similar, the middle line may be considered as the axis of the equilibrium, in which the centre of gravity of that surface is to be found; and as the surface of the upper water-line, and so of the others, has been already divided into equal parts, and the breadths taken at the several timbers or ordinates to find the displacement, we have only to observe that the spaces between those timbers are here considered as so many parallelograms, the centres of gravity of which parallelograms will form a system distributed on the middle line.

Then to find the centre of gravity of the system, in respect to the aft-side of the rudder, which is assumed for the first term of the momenta, we need not find the centre of gravity of each parallelogram, but divide the whole surface into three sections, and multiply their sums, as before, by the distance between the ordinates, and the product will be the area of each section.

Then to obtain the sum of the momenta of all the elementary parts of the surface, multiply the breadth of each ordinate into its distance from the axis of the momenta, or first ordinate; then take the sum of all these products, and, by multiplying this sum by the distance between the ordinates, we shall have the sum of all the momenta of the elementary parts of the surface; which, divided by the sum of the ordinates, will quote the distance of the centre of gravity of the whole surface from the axis of the momenta.

Lastly, the areas of the several planes or surfaces, and their momenta, being found, divide one by the other, and the quotient will be the distance of the centre of gravity of the whole section from the aft-side of the rudder.

		Ft.	In.
Length on the upper side or plane of the keel	}	177	2

Cubic feet displaced - - -  
× by pounds in a cubic foot of salt-water

94542.162  
64.375

6086151 lbs.

As the estimated weight of the ship, with every thing on board, was 6,295,145 lbs. we find, by the above calculation, the upper water-line, as parallel with the keel, is placed too low, as the displacement is only equal to 6,086,151 lbs. Therefore proceed to find if the body of the ship is constructed to sail on an even keel, that is, whether the ship will be in her natural position when brought down to that line. For this purpose, let the centre of cavity, or centre of support, be next found, as then we may discern what proportion the displacement of the fore-part of the ship bears to the aft-part; for, should they not prove equal, the ship cannot be constructed to sail on an even keel.

Distance of the centre of gravity of the section of the stem and knee from the aft-side of the rudder	- - - -	- - - -	176 1

### Areas of the several planes, and their momenta.

Ft. In.	Ft. In.
130 3½	Area of the after-plane 130 3½
	Mult. by 26 9½ its momentum = 3487 8½
3461 4	Area of midship-plane 3461 4
	Mult. by 100 1½ its momentum = 346566 0
157 8	Area of the fore-plane 157 8
	Mult. by 163 11 its momentum = 25844 2½
9 0	Area of rudder and post 9 0
	Mult. by 35 its momentum = 30 9
6 5½	Area of stem and knee 6 5½
	Mult. by 176 1 its momentum = 1137 2½
3764 8½	Whole areas. Sum of momenta 377065 10¾

Now 377065 ft. 10¾ in. divided by 3764 ft. 8½ in. gives 100 ft. 1¾ in., the distance of the centre of gravity of the whole section of the first or lower horizontal water-line from the aft-side of the rudder.

# SHIP-BUILDING.

## Operation for the Plane of the Keel, &c.

To find the centre of gravity for the plane of the keel, &c.

The length on the upper side or plane of the keel, from the aft-side of the rudder, is	Ft.	In.
Multiplied by its thickness	177	2
Area of the plane	265	9
Distance of its centre of gravity from the aft-side of the rudder, being equal to half its length	88	7

Now 265 feet 9 inches, multiplied by 88 feet 7 inches, is equal to the momentum 23540 feet  $1\frac{5}{8}$  inch.

The centres of gravity of the six planes having been found, the distance of the centre of gravity of the whole bottom of the ship, from the aft-side of the rudder, is obtained as follows:

From the principles already explained, the distance of the centre of gravity of the bottom, from the aft-side of the rudder, is equal to the sum of the momenta of an infinite number of horizontal planes, divided by the sum of these planes; or, which is the same, by the solidity of the bottom. As, however, we have no more than six planes, we must conceive their momenta as the ordinates of a curve, whose distances may be the same as that of the horizontal planes.

Now the sum of these ordinates, or planes, except the first and last, of which take but half, being multiplied by their distance, gives the surface of the curve; of which any ordinate whatever represents the momentum of the horizontal plane at the same height as these ordinates; and the whole surface will represent the sum of the momenta of all the horizontal planes.

	Area of the Planes.		Momenta.	
	Ft.	In.	Ft.	In.
Half of the upper	3860	11	371559	$3\frac{7}{8}$
All the fourth	7052	$3\frac{1}{2}$	684659	$9\frac{7}{8}$
third	6183	$5\frac{1}{2}$	604650	$6\frac{1}{2}$
second	5119	$9\frac{1}{2}$	503831	$9\frac{1}{2}$
first	3764	$8\frac{3}{4}$	377065	$10\frac{3}{4}$
Half the keel	132	$10\frac{1}{2}$	11770	$0\frac{3}{4}$
Sum	26114	$0\frac{3}{8}$	2553537	$4\frac{1}{2}$

Now 2553537 feet  $4\frac{3}{8}$  inches, divided by 26114 feet  $\frac{3}{8}$  of an inch, gives 97 feet  $9\frac{3}{8}$  inches, the distance of the centre of gravity of the bottom of the ship from the aft-side of the rudder.

The height of the centre of gravity of the bottom may be thus found.

To half of the plane of the keel and half of the upper horizontal plane, add all the intermediate planes, and multiply them progressively as before, taking the upper side of the keel for the axis of the momenta; then that sum being multiplied by the distance between the planes, and divided by the sum of the planes, taking half of the first and last, gives the height of the centre of gravity of the bottom above the keel.

	Area of the Planes.		Distance from Keel.	Products.		
	Ft.	In.		Ft.	In.	
Half of the keel	132	$10\frac{1}{2}$	× by 1 =	3764	$8\frac{3}{8}$	
All the lower	3764	$8\frac{3}{8}$		2 =	10239	7
second	5119	$9\frac{1}{2}$		3 =	18550	$4\frac{1}{2}$
third	6183	$5\frac{1}{2}$		4 =	28209	2
fourth	7052	$3\frac{1}{2}$		5 =	19304	7
Half the fifth	3860	11				
Sum	26114	$0\frac{3}{8}$		80068	$5\frac{1}{8}$	

Now 80068 feet  $5\frac{1}{8}$  inches, divided by 26114 feet  $\frac{3}{8}$  of an inch, gives 3 feet  $\frac{3}{4}$  of an inch; which, multiplied by 3.6 feet, the distance between the horizontal sections, gives 11 feet  $\frac{1}{4}$  of an inch, the height of the centre of gravity of the bottom of the ship above the under side of the keel.

The height of the centre of gravity of the bottom of the ship, and its distance from the aft-side of the rudder, being found, the ship being supported in an upright position, the centre of gravity will necessarily be in the perpendicular longitudinal section, supposed to divide the ship in two equal and similar parts at 97 feet  $9\frac{3}{8}$  inches, the distance of the centre of gravity of the bottom of the ship before the aft-side of the rudder, which comes between the frame 6 and 2 in the after-body. It may now be ascertained whether the ship will be in her natural position when floating at the upper horizontal line, or constructed to sail on an even keel. Thus, separate the displacement of that part of the bottom before the centre of gravity or support, and see how it agrees with that part of the bottom abaft it, as we may then examine the difference, if any, as in the following examples.

# SHIP-BUILDING.

Find the Displacement or Solidity of the Bottom before the Centre of Gravity or Support, which is 5 ft.  $\frac{5}{8}$  in. abaft Frame 2.

## SHIP-BUILDING.

By the result of the above calculation it appears, that the after-part of the bottom has a minus of 983.3224 feet, its contents being 983.3224 less than the fore-part; and was the ship to be constructed to sail on an even keel, it would be necessary to fill the after-part half the difference, or 491.6612 feet, and reduce the fore-part until it had lost the same quantity; but to alter the after-part of the ship from its present construction, or to make it fuller, would retard her velocity, and prevent the water collapsing at the rudder; for the run of a ship should be neither too fine nor too full, but so constructed that the column of water should exactly meet upon the stern-post, then the rudder will have its full power. The quarter above the load-water-line should be very full, to support the ship when rising forward to a sea, and also to enable her to fend.

In regard to the failing trim of a vessel, it is the decided opinion of most scientific men, that ships or vessels of the larger classes should always be so constructed as to sail on, or nearly on an even keel, that is, so that the ship, when trimmed for sailing, should have her keel parallel to the surface of the water; therefore, by as much as the effort of the wind on the sails and masts in forcing the ship through the water has a constant tendency to depress the bow, so much should the ship be trimmed by the stern, as that will be found most advantageous both to their sailing and steering.

Many think it inconsistent to construct a ship to sail on an even keel, and yet to place the midship-bend or greatest breadth very forward. A ship so intended to sail, ought, as they conceive, when launched, to have an equal bearing fore and aft, in order that, before the ballast is stowed, she may be on an even keel; and they think that the ballast, if not placed equally fore and aft, must inevitably strain the sheer of the ship. Nevertheless, experience convinces us it is not materially detrimental; for many ships, when launched, will swim four feet by the stern, more or less, and yet when trimmed for sailing, they are found to go faster on an even keel, and receive little or no damage if carefully stowed.

Some ships are too clean abaft, and require to sail by the stern; because they have no bearing for fifteen or twenty feet from aft, till the buttock is brought well into the water; and even then, for want of being fuller lower down, when the sea leaves the buttock, the over-hanging of the stern will strain the ship, and occasion her to tremble, till the next sea, with redoubled force, strike the buttock as the stern is falling, and so shake the ship; in which case it will be well, if some part of the masts be not carried away by the shock: however, this kind of motion must retard the velocity. This accident, though rare, is dangerous, and should be prevented in the construction of the ship.

With respect to ships that ought to sail some feet by the stern, on account of their insufficiency abaft, it is the opinion of many, that if a line were drawn to be well with the lower side of the keel, in the middle of the ship's length, and half the difference set up at the aft-part of the stern-post from the lower side of the keel, and that part of the keel and dead-wood were taken off, and placed under the fore-part of the keel, with the after-end that was before to be forward, so as to make the lower part of the keel straight, as before, the ship would then sail somewhat faster, and be the better: for when a ship is brought so much down by the stern, the keel, not being parallel to the surface of the water, (to which the ship generally sails parallel,) must occasion a pressure at the under side of the keel, equal to the weight of water displaced by the breadth of the keel, and to the angle which the keel makes with the surface of the water in its own length. This may shew why so many ships, differently constructed, are found to sail best on an even keel, although many of them were

designed by the constructor to sail by the stern. Finding the result rather in favour of an even keel, the 74, *Plate I.*, was so constructed, as most likely to answer every purpose. By that means the water-lines were drawn parallel to the keel, and were thereby more useful as well as more properly placed to form the body; for when the square timbers, and the water-lines, being square to the timber, properly agree with each other, and are fair curves, the ribband-lines, or any other section, will likewise be fair, or as fair as they should be, allowing the preference to the water-lines and square timbers.

When water-lines are not designed to be parallel to the keel, the draught is generally formed by ribband-lines, because the water-lines differing in height at every timber, require the square timbers to be formed before their height can be set off; and when the water-lines are run, if not approved of, much of the work must be done over again, the water-lines being more regarded than the ribband-lines; for many ships are constructed by ribband-lines only, which seem to produce fair curves, yet forward, and aft especially, they make a very unfair body, which is detrimental to velocity.

Small vessels, as cutters, &c. draw much more water aft than forward, and their bows are more full in proportion to the after-part; nor would it answer so well were their line of floatation nearly parallel with the keel, but spreading as it does aloft, especially towards their bow, the bow meets the fluid in a more slanting direction, and experiences far less resistance; and the depression of the stern, with the impulse of the aftermost sails, causes a proper counter-balance, and propels the vessel through the water with greater velocity than if otherwise constructed; for the after-part of those vessels is generally very clean or tapering, which necessarily contributes to make the vessel weatherly, and causes it, under judicious management, to turn as it were on a pivot.

A ship may be built to a precise draught of water, by which the construction will be founded upon true principles; but when a ship is not built to one precise draught more than another, it will be a very difficult, and one of the most complex questions in ship-building to determine this point. It may be imagined that no more is necessary than to make the ship swim in the water, so as to be capable of carrying the greatest sail; but when a ship is very deep in the water, it will greatly increase the resistance, and consequently retard her sailing; hence a long ship will draw less water than a short one, which is a good property, and the resistance at the stern being less, she will therefore sail faster. The resistance, however, must be calculated, not absolutely, but relatively, and in proportion to the sail she spreads.

In ships of war, the load-water-line must be governed by the height of the lower ports above the water in midships; and thus we find in line-of-battle ships should invariably be from five to six feet, in frigates from six to seven feet, and in sloops, cutters, &c. from four to five feet.

Ships for commerce are generally constructed to carry a certain cargo, and their principal dimensions are determined according to the trade for which they are particularly designed; therefore the line of floatation, or load-water-line, is not confined in them so exactly to a certain height.

Ships of the line, from long practice, have been found to sail best when inclined one foot, or rather more, by the stern. Thus, the 74-gun ship in *Plate I.* load-water-line, when fitted for sea, was 20 feet forward and 21 feet abaft; therefore it only remains to be ascertained, whether the whole displacement of the bottom under the load-water-line agrees with the estimated weight of the ship, &c. when fit for sea, by multiplying the mean area of the load and upper horizontal water-lines by six inches, the mean depth, and adding it to the displacement already found: as in the following operation.

# SHIP-BUILDING.

## Area of the Load-Water-Line.

Total displacement of the ship under the load-water-line											2829	tons			175	lbs.

We now find that the 74-gun ship, *Plate I.*, load-water-line, is not only properly placed with regard to her bell failing trim, but the displacement also agrees with the estimated weight of the whole ship when fit for sea, which was 2810 tons 745 lbs., or exceeds it by 18 tons 430 lbs., which is better; as the bias should rather lead to increase than diminish in capacity, and favours any little inaccuracies in the admeasurements; though surely there is little room for error in either extreme, if proper attention be paid to the subject. In like manner may, therefore, the weight of any other ship be found; and, by reducing the displacement of the bottom into cubic feet, we may always ascertain if the load-water-line in the draught be properly placed.

### *Stability, or Stiffness.*

The stability or stiffness of a ship comes next under consideration, being a quality no less essential to the safety of navigation than capacity; and without which a ship is totally disqualified for the purposes of war, being unable to use her guns with effect, or carry a press of sail in case of emergency.

Before we proceed further, the following particulars, as they relate to vessels at rest, or in motion, should be defined.

The *centre of cavity*, or *displacement*, already mentioned, is the centre of gravity of the volume of water displaced by the immersed part of the ship's bottom; and is also the

centre of all the vertical force that the water exerts to support the vessel; for as heavy bodies by their gravity endeavour to approach the centre of the earth in a vertical line, passing through their centre of gravity, tending directly towards the centre of the earth; so the pressure of fluids endeavours to carry bodies in a vertical line tending from the centre of the earth towards their surface, and passing through the centre of gravity of the immersed part, which forces them towards the surface; so also in any immersed body at rest these two opposite forces coincide in the same vertical line, acting in a quite contrary direction to one another. Thus, every floating body is necessarily supported, or pressed upwards, by the fluid with a force equal to its weight, or pressure downwards, otherwise no body could remain at rest on a fluid, but would ascend or descend as the prevailing force determined: and the moments of all the forces with which a floating body presses on a fluid, and the moments of the forces of the fluid which supports the floating body, are equal and contrary, and are resolved into the same right line, perpendicular to the plane of the fluid. But as this centre depends upon the shape of the body immersed, it of course varies with every inclination of a ship; and whilst the centre of cavity goes faster, and further over to the ship's side in her motions, so as to keep without the perpendicular of the centre of gravity, the ship will be supported; and the water will act upon the centre of cavity

## SHIP-BUILDING.

cavity in the immerfed body with more or lefs power, in proportion to its diftance without the centre of gravity, to bring the fhip upright, where the acting force or power ceafes which occafioned the vefel to heel.

The *line of fupport* is the vertical or perpendicular line fuppoted to pafs through the centre of gravity, and interfecing a line perpendicular to the keel of the vefel through the point, called the *meta-centre*. For if a floating body is inclined by any power which does not change the pofition of its centre of gravity, the line of fupport mult neceffarily pafs between that power and the centre of gravity; and the force or moment of that power is equal to the weight of the floating body, multiplied into the diftance of its centre of gravity from the line of fupport. As the line of fupport mult pafs between the centre of gravity and the power applied to heel the vefel, the moment of that power, or its force, multiplied into its diftance above the meta-centre, is equal to the moment of its gravity, or the weight of the floating body multiplied into the diftance of the centre of gravity below the meta-centre.

Suppofe the vefel inclined, or heeling by the power of the wind on the fails, if the line of fupport paffes on the windward-fide the vefel would upfet, as the power and gravity are at the fame fide operating to incline it; but if it paffes to the lee-fide of that power, the vefel will be redreffed, as the power and weight operate to that effect; and if the moments of the power and gravity be not equal, the body will not remain at reft, but will incline more or lefs, as the power or the weight prevail.

Hence it is plain, that the diftance from the centre of gravity to the line of fupport, multiplied into the weight of the vefel, is the meafure of the ftability of the vefel, or its effort to redrefs itfelf when inclined, and that its ftability is as that diftance.

The *meta-centre* ufually fignifies a point to which, if the centre of gravity of a floating body be raifed, the fmalleft lateral effort will make it incline. It is plain, that in an homogeneous cylinder, or fphere, the meta-centre, and centre of gravity, being always in the fame point or centre of the fphere, however thefe bodies are inclined, have no ftability. The centre of gravity mult, by no means, be placed above the meta-centre, becaufe if it were the vefel would overfet. This centre, which has likewife been called the *fhifting centre*, depends upon the fituation of the centre of cavity, for it is that point where a vertical line drawn from the centre of cavity interfefts a line paffing through the centre of gravity, and being perpendicular to the keel.

The *centre of gravity* of a fhip, is that point by which it may be fufpended, and the parts remain in perfect equilibrium. It is alfo the centre of all the forces, or momenta, which prefs it vertically, or directly downwards towards the centre of the earth.

The lower the centre of gravity is placed, the farther is it from the line of fupport, and confequently the greater ftability.

In fhips of war, the centre of gravity can never be far removed from the load-water-line; for if the centre of gravity could be placed nearer the keel, it is not to be defired, as the farther it is removed from the load-water-line, the rolling of the fhip becomes more uneasy.

The *centre of motion* is that point upon which a vefel oscillates or rolls when put in motion. This centre is always in a line with the water's edge, when the centre of gravity is even with, or below the furface of the water; but whenever the centre of gravity is above the water's furface, the centre of gravity is then the centre of motion.

The *longitudinal axis* of a fhip is an imaginary line, which paffes horizontally from head to ftern through the centre of gravity.

The *tranfverfe axis* is an imaginary horizontal line, paffing athwartfhips through the centre of gravity.

The *vertical axis* is an imaginary perpendicular line, drawn though the centre of gravity when the vefel is in equilibrium.

It is about thefe axes that every fhip or vefel in motion may be fuppoted to turn. In rolling, the may be fuppoted to oscillate on the *longitudinal axis*; in pitching, on the *tranfverfe axis*; and in working, &c. to turn on her *vertical axis*.

From constantly obferving that the performance of fhips at fea depends materially on their ftability, both naval architects and navigators mult, at all times, be defirous of difcovering in what particular circumftances of conftruction this property confifts, and according to what laws the ftability is affected by any varieties that may be given to their forms, dimensions, and difpofition of contents; which are determined, partly according to the fkill and judgment of the conftruftor, and partly, in fome vefels, as we fhall fhew, by adjustments after the vefel is afloat.

The form of the immerfed body, and the weight of the fhip, are the chief terms in the compofition of ftability, and they are only to be attained, in the requifite degree, by full dimensions near the load-water-line, with fufficient capacity.

At firft fight, it is certain that all the weight above the load-water-line helps to make the fhip crank, and, of confequence, the lighter the upper works the ftiffer the fhip.

Conftruftors may vary the form of a fhip chiefly in three dimensions, that is, in the length, breadth, or depth: let us examine how far enlarging of fhips, in any of thefe particulars, will contribute toward making them carry fail, or, in other words, gain ftability; for although the wind may, in one fenfe, be faid to conftitute the power by which fhips are moved forward in the fea, yet if it acts on a vefel deficient of ftability, the effect will be to heel the fhip rather than to propel it forward; ftability is, therefore, not lefs neceffary, than the impulfes of the wind are to the progrefive motion of vefels.

If the *length* only, without altering the other dimensions, be enlarged, the centre of gravity and the meta-centre will continue the fame height, and her ftability in refpect of inclination to one fide will increafe in proportion to the weight of the fhip; and as the weight generally increafes or diminifhes in proportion to the length, we may fay that in fhips that differ only in length, their ftability will be in proportion to their length.

Yet although an increafe of length would enable a fhip to carry the moft fail, confequently fail fafter, it mult not be carried to an extreme; becaufe if fo conftrufted, a fhip would neither tack nor veer fo quickly; neither would the lift or rife in a fea like one fhorter; the would ftrain more, and be very liable to have the fea break over her. The influence of the rudder may be weakened, and may even be totally loft. The greateft judgment is therefore required in proportioning the length, which may be proportionally greater in thofe fhips that generally navigate in the fmoother feas, or are not intended to be deeply laden.

By altering the *breadth*, the ftability is materially affected; for by enlarging it we gain, and by diminifhing the breadth we lofe a great deal of the ftability. M. Bouguer has proved, that the ftability increafes in proportion to the cubes of the breadths: for, fuppofing the bottom homogeneous, then, 1ft, the increafe of weight, and of confequence ftability, will be double the increafe of the breadth; and 2dly, the additional weight will act with fo much the greater force, as the length of the lever is increafed, or as the meta-centre is raifed, and the height of that point is augmented in proportion to the fquare of the breadth: hence the ftability will

## SHIP-BUILDING.

will be increased in proportion to the cube of the breadth ; for example, without altering the other dimensions, let the breadths be doubled, we thereby double the weight, which, by acting upon the arm of a lever, double the length will be quadruple, so the ship will acquire eight times the stability.

Thus we see an increase of breadth will produce an increase of stability ; for a ship that is broad and shallow has much more stiffness than one that is narrow and deep ; but the sailing of the ship may be much retarded, as she certainly would be leewardly under little sail, which ought to be particularly guarded against, especially in contracting large ships of war. The expence in the building would also be materially increased, according to the usual mode of computing the tonnage, as may be readily seen in the next section.

If the *depth* only is increased, without enlarging either the length or breadth, all the stability that can be gained will be in the stowage. To increase the depth or draught of water would lower the centre of gravity, and increase the weight ; this would operate against velocity, because the resistance is as the quantity of water to be removed ; or nearly as the area of the thwartship section of the immersed part of the body at the midship-bend. It would at the same time render the immersed body of a figure less proper to separate the line of support from the centre of gravity, so that the effect on one side would be in some measure destroyed on the other ; and, by lowering the centre of gravity too much, the ship would labour excessively, and endanger the masts, too large a draught of water being both dangerous and inexpedient.

Ships having a sufficient degree of stability arising from their construction, will certainly sail faster than others, which, in order to carry the same quantity of sail, require to be ballasted with a much greater weight ; for the latter, so ballasted, will be much more liable to roll than the former.

The following circumstance will prove, that instability in the construction cannot be rectified to any considerable degree by the stowage, although, on the contrary, that the stability of many ships, however perfect in construction, may be materially injured by improper trim, or an injudicious mode of stowage.

And, first, as there is nothing of more importance to the well-being of a ship than its stability, it will not be improper to mention an opinion which prevails with seamen in general, that the stability depends chiefly on the stowage of the hold ; and at the same time, in order to shew that a very great change in that respect will produce a very trifling difference in the stability, we shall quote a professional author of great merit, M. de Romme, in his book *L'Art de la Marine*, page 105. "As to the position of the centre of gravity, no doubt it may vary, but the limits to which it is confined are very strait, especially in ships of war. An example in the *Scipio*, of 74 guns, armed for the first time in 1779, was hardly in the road before she was suspected of instability. It was important in time of war to clear up those doubts, and to make the necessary experiments to prove this dangerous defect, if it existed. First, the lower-deck guns were run out on one side, while hoisted on the other, which heeled the ship thirteen inches ; the ship's company were then ordered to their quarters at the side the guns were out, which increased the inclination to twenty-four inches. After these essays the sails were set, and in fine weather the ship was found so crank, as to render the use of the lower-deck guns difficult and dangerous : thus, her instability being proved, she was ordered to port to be remedied.

"Opinions were divided as to the cause of the defect ; some imagining it to proceed from the form of the hull ; others from the ill arrangement of the charge. The first engineer was ordered to attend at Rochfort, and direct the choice of measures to give the *Scipio*, as well as two other

ships, the *Pluto* and *Hercules*, built from the same plan, the stability they wanted. He judged that new stowage would remedy the defect, and his opinion was adopted by the marine council. The *Scipio* was unloaded, and charged anew, under the direction of the chief engineer. In the first charge she had 84 tons of iron, and 100 tons of stone ballast, and was re-loaded with 198 tons of iron, and 122 tons of stone ballast ; and as her draught of water, or displacement, could not be altered, it was necessary to diminish 130 tons of water to preserve the same line of floatation ; by this means 136 tons were placed, in the second loading, eight feet lower than in the first ; yet when the ship was completed with the new distribution of her charge, she was found precisely as deficient as before, inclining twenty-four inches, with the men at quarters, and the guns out. She was afterwards doubled with light wood, a foot thick at the extreme breadth, and ten feet under water, decreasing to four inches length and depthways."

M. de Romme very judiciously observes, that the defect of instability was not so much owing to a want of extreme breadth, as several other 74-gun ships had had the same, or even less, but in diminishing the breadth at the plane of floatation too quickly forward and aft, which at once lessened the capacity and position of the line of support.

A French 36-pounder weighs, with carriage, &c.  $4\frac{1}{2}$  French tons, and their increased length causes their centres of gravity, when run out, to be removed  $4\frac{1}{2}$  feet ; so that the moment produced by running out the lower-deck guns of a French 74, the opposite side hoisted, is more than double the moment for an English 74, in the same circumstance.

It is certain this change of place in the centre of gravity, which lowered it nearly five inches, must have contributed to increase the stability, and have occasioned nearly a difference of three inches in the greatest inclination ; but as the experiment where the men are stationed at quarters is liable to such irregularity, an error of this magnitude is to be accounted for from the men running to the side, to mark more strongly the defect of a bad ship.

Secondly, the stability of many ships, however perfect in the construction, may be materially injured by an improper trim, or an injudicious mode of stowage ; for was the centre of gravity raised too high by the weightiest part of the cargo being placed uppermost, the ship would not only be rendered incapable of carrying a sufficient quantity of sail, but in danger of being overfet ; and was the cargo lead, or any other such weighty body, and placed too low in the hold, the centre of gravity would consequently be so lowered as to endanger the ship's rolling away her masts. When a ship is so loaded, as that her centre of gravity is carried too far forward, the ship will pitch and labour heavily ; and when too far off, she will occasionally be exposed to the dangerous circumstances of a pooping sea, &c.

As it is of the utmost importance to the well-being of a ship to ascertain its stability, the greatest attention must be given, in the construction, to the finding of the exact distance, between the meta-centre and centre of gravity, that every ship requires, according to her form ; the maximum of which is, that the ship shall not, by the length of lever, either become too stiff, or be subject to sudden motion or rolling ; nor, on the contrary, from the lever's being too short, the vessel is unable to carry sail. Therefore, in the construction, to ascertain the height of the meta-centre above the centre of gravity of the immersed part of the bottom, the half section of the load-water-line must be taken as was divided to find the displacement. Then the sum of the cubes of the half sections, or ordinate is to be multiplied by the distance between them, and the product

# SHIP-BUILDING.

product are to be divided by the immerfed part of the bottom of the fhip.

is the fame, and the volume of the immerfed part of the bottom remains alfo the fame, the altitude of the meta-centre will remain the fame, whatever may be the form of the bottom.

The above operation gives 14 feet 9½ inches, the height of the meta-centre above the centre of gravity of the immerfed part of the bottom of the 74-gun fhip, *Plate 11.*

Now let us fee how the above calculations in determining the height of the meta-centre above the centre of gravity agrees with actual experiment; for theory (particularly in the constructing of fhips) that agrees with experiment is only

to be regarded. We are in this particular indebted to the late admiral Lefevon Gower, who directed feveral experiments to be made to try the relative itability of the following fhips of war, by heeling them with their lower-deck guns out on one fide, and houfed on the other; and afterwards with their men at quarters, the guns remaining as above.

# SHIP-BUILDING.

As the inclinations of the Brunswick and Bedford are omitted in the first experiment, we shall only compare the relative stability of the other three ships, which are quite sufficient to explain every thing necessary to be remarked on the subject. It is to be regretted that the first inclination of the Brunswick was omitted, as it comes the nearest to *Plate I.*

or displacement of		Barfleur*	3360	
the - - -		Bombay Castle	2700	

\* The difference of the draught of water of the Formidable and Barfleur,  $14\frac{1}{2}$  inches, gives at least 210 tons difference in the weight. Both ships have similar dimensions nearly, and are supported on an even keel.

These three ships have the same number and weight of guns on the lower gun-deck; therefore the moment of the guns, whether quite exact or not, does not signify, as any error will not have a partial influence. We suppose each gun and carriage together to weigh three tons, and allow three feet removal when the gun is run out; and as there are 14 guns run out in each ship, the equal moments for them is  $3 \times 3 \times 14$ , or 126 tons at three feet: the weight on one side the balance is 42 tons, at three feet distance from the support; and on the other, in the Formidable, 3150 tons, at 48 hundredths of an inch (less than half an inch), which will be found to balance 42 tons at three feet:—for the Barfleur 3360 tons, at 45 hundredths of an inch, which will balance 42 tons at three feet; for the Bombay Castle 2700 tons, at 56 hundredths of an inch, which will balance 42 tons at three feet.

Having found the distance each centre of gravity is separated from the line of support, which is in these small inclinations the same as the sine of the angle; the cosine, or distance of the centre of gravity from the meta-centre, is easily known, and will be found to be, for the

	Ft.	In.	
Formidable's centre of gravity	3	$5\frac{1}{10}$	} below the meta-centre.
Barfleur's	3	$9\frac{7}{10}$	
Bombay Castle's	4	$5\frac{7}{10}$	

When the Formidable and Barfleur were farther inclined by the men at quarters, the Barfleur continued to have one-seventh more stability than the Formidable; which proves that the Formidable's centre of gravity was above the line of floatation; for otherwise, as her immersed body was better calculated to separate the line of support from the centre of gravity than the Barfleur's, she would have inclined less proportionably, if the centre of gravity had not acted against her stability: 100 tons of iron ballast at the keelson would have only increased her draught of water six inches, and have given her more stability than the Barfleur, leaving her the advantage of six inches more height for her ports, and nearly 34 feet square less resistance at her mid-ship-bend. Thus it is demonstrable, that those ships should have no more shingle ballast than is necessary for the ground tier, and should have above 200 tons of iron; nor would there be any danger of their being labourfome, as their centre of gravity would be but at the line of floatation or load-water-line. The same regulation should prevail with the first-rates.

The Bombay Castle is certainly stiff enough, yet no doubt her lower deck might have been placed six inches higher without any detriment whatever to the ship, and her ports would of consequence have been at a reasonable height from the water.

In *Plate I.* we find, by the preceding calculations, that the

centre of gravity of the immersed part of the bottom was above the under side of

	Ft.	In.
The keel - - - - -	11	$0\frac{1}{4}$
The meta-centre above the said centre of gravity	14	$9\frac{7}{10}$
	<hr style="width: 100%;"/>	<hr style="width: 100%;"/>
	25	$10\frac{7}{10}$
And the centre of gravity is four inches above		
the load-water-line at the centre of cavity,	20	$10\frac{7}{10}$
which makes it - - - - -	<hr style="width: 100%;"/>	<hr style="width: 100%;"/>
Centre of gravity below the meta-centre -	5	0

Which we find exceeds the Bombay Castle's; and the ports in *Plate I.* are five feet eight inches above the water.

By the above experiment we observe, that the guns being run out on one side and housed on the other, inclined the ship to a certain point, and at the same time there was an exact equilibrium between the momentum of the guns, and the whole weight of the ship on each side the line of support in the direction of the vertical effort of the water. The centre of gravity of the ship is in the same vertical line with the meta-centre when the ship is in an horizontal position; and the more the ship inclines, the more will the centre of gravity of the ship be removed from the vertical line of the meta-centre, or line of support. Hence it is plain, that the distance of the centre of gravity from the line of support is always in proportion to the sine of the inclination; at least when the inclination is but small, as before observed. Now, if that distance, and likewise the whole weight of the ship, be known, we have also its momentum, or the relative force with which that weight acts in endeavouring to right the ship, and bring her again into an horizontal position, and which is the measure of her stability; but since both the situation, and likewise the weight that produces the inclination, are known, we may thence know if the momentum of one be equal to that of the other, and thereby easily discover if the centre of gravity be in that very point we propose.

The success of the above experiment (which might be rendered very useful if more frequently tried) depends on the nicety to be observed in taking the exact quantity of the angle of inclination: to attain this, a level line for the sensible horizon of the sea may be used, or, what is much better, a plumb-line fastened to the head of the mast, taking its distance from the heel of the mast, both when the ship is upright, and likewise when she heels. The plumb-line seems to be the most convenient, because we have thereby immediately the proportion in which the centre of gravity recedes from the vertical line of the meta-centre, which will always be in proportion to the distance of the plumb-line from the heel of the mast. During the whole time of the operation, it is necessary to be very careful to render all the circumstances absolutely the same, so as to be well assured the inclination is produced only by the momentum of the guns, &c.

We may in this manner prove the centre of gravity of the 74-gun ship, *Plate I.*, knowing the height of the meta-centre; for, having the quantity of the weight producing the inclination, (which is the same as the above,) and examining the distance of the centre of gravity from the line of support in which the effort of the water exerts itself, we have also its momentum, or its relative force, which is equal to the whole ship, since these two exactly balance one another; so that it is only dividing this momentum by the whole weight of the ship, and the quotient will give us the distance of the centre of gravity of the ship from the line of support, or vertical line of the meta-centre.

For the Bombay Castle of 74 guns and 2700 tons, in estimating

# SHIP-BUILDING.

estimating the weight or displacement, it was found, that 56 hundredths of an inch balanced 42 tons at three feet; and it will be found by the following operation, that 53.445 hundredths of an inch in *Plate I.* will balance 42 tons at three feet, *Plate I.*, displacement 2829 tons 175lbs. =  $2829.078 \times 53.445 = 151200.0 \div 1200 = 126$ .

We now find that the distance of the centre of gravity is removed from the line of support 53.445 hundredths of an inch. After this, it will be easy to discover how far the centre of gravity is below the meta-centre, since there will be the same proportion betwixt the distance of the plumb-line from the heel of the mast, and the height of the mast, that there is betwixt the distance of the centre of gravity from the line of support. Thus, the length of the mast is 112 feet, which multiplied by 53.445 = 5985.8  $\div 1200 = 4$  ft. 11  $\frac{1}{2}$  in., the distance of the centre of gravity below the meta-centre nearly agrees with the calculation above given.

### *Tonnage or Burthen.*

By the tonnage of a ship, is meant to convey the idea of the *weight of the cargo* she is intended to carry from her light to her load water-line, or seat in the water, when best equipped for sea. It may also be called the ship's *real burthen*. Therefore, to ascertain the true burthen or tonnage by calculation, is a question of equal importance and difficulty, as preceding displacement, &c.

It is of importance, because it is by this that the merchant or freighter judges of the fitness of the ship for his purpose; and although customary rules are given for computing the tonnages of ships, the bare inspection of them will prove how futile they are. It would be very difficult to fix upon any general rule which shall be very exact, because it depends not only on the cubical dimensions of the ship's bottom, but also on the scantling of her whole frame; and, in short, on the weight of every article to complete the said ship ready to receive on board her cargo. The weight of timber is variable; the scantling of the frame being no less so.

The following rules for computing the tonnage of a ship are commonly adopted and made use of between the contractor and the builder, at a certain rate *per ton* for the building, and will be found to be quite unconnected with the above definition of a ship's tonnage; for as the depth is out of the question, the contractor finds a saving in less breadth and great depth, which make against stability, and consequently injure the velocity: on the contrary, great breadth and less depth will be found more advantageous to the builder: thus are the interests of the two parties oppositely concerned in the result, and both, when carried to the extreme, are exceedingly injurious to the construction of vessels.

### *The general Rules observed for measuring the Tonnage of Ships in the Royal Navy and the Merchants' Service.*

Let fall a perpendicular from the fore-side of the stem, at the height of the upper deck, or middle deck, in three-deck ships, and another perpendicular from the aft-side of the main-post, at the height of the wing-transom. In merchant-ships, the foremost-perpendicular is let fall from the fore-side of the stem, at the height of the wing-transom. From the length between these perpendiculars, deduct three-fifths of the extreme breadth, (that is the thickness of the bottom plank on each side added to the moulded-breadth,) and likewise as many 2  $\frac{1}{2}$  inches as the wing-transom is above the upper edge of the keel, and the remainder is reckoned the length of the keel for tonnage.

Then multiply the length of the keel for tonnage by the extreme breadth, and that product by half the extreme breadth; then dividing by 94, the quotient will be the burthen, in what may be denominated builder's tonnage.

Calculation of the burthen in tons of the 74-gun ship, *Plate I.*, according to the common rule.

	Ft.	
Length from the fore-side of the stem, at the height of the upper deck, to the aft-side of the main-post, at the height of the upper side of the wing-transom	182	9 $\frac{1}{4}$
Three-fifths of the extreme breadth is - - - -	29	2 $\frac{1}{2}$
The height of the wing-transom is 26 ft. 10 in., which produces for every 2 $\frac{1}{2}$ inches - - - -	5	6 $\frac{3}{4}$
	34	9 $\frac{1}{4}$
Length of the keel for tonnage - -	148	0
Multiplied by the extreme breadth - -	48	8
	7203	8
Multiplied by half the extreme breadth - -	24	4
Divided by 94 - - - - -	175248	0
Burthen in tons, according to the common rule - - - - -	1864	7 $\frac{1}{4}$

### Estimate, shewing the real burthen of the 74-gun ship, *Plate I.*

	Tons.	lbs.
The weight of the ship at the launching draught of water - - - - -	1377	2198
The weight of the furniture, including the sheathing - - - - -	204	1040
The weight of the ship at her light water-mark - - - - -	1582	998
The weight of the ship at the load water-mark - - - - -	2829	175
From which deduct the weight at the light water-mark - - - - -	1582	998
Real burthen - - - - -	1246	1417
Burthen in tons, according to the common rule - - - - -	1864	763
Difference - - - - -	617	1585

By the above it may be readily seen, that the 74-gun ship (*Plate I.*) will not carry the number of tons she is rated for, by 617 tons 1585 lbs.; and hence the impropriety of such a rule being made general, as it will always be found greatly to increase the tonnage of sharp-built vessels; while those that are full-built, as ships in the East India Company's service, will carry a great deal more. We shall, therefore, calculate the tonnage of the East India ship (*Plate XII.*) both ways as above, in order to prove the great inaccuracy of the rules with respect to those vessels, as well as to ships of war.

# SHIP-BUILDING.

Calculation of the burthen in tons of the East India ship, (Plate XII.) according to the common rule.

	Feet.	
Length from the fore-side of the stem, at the height of the upper side of the wing-transom, to the aft-side of the main-post, at the said height of wing-transom, is	159	
Three-fifths of the extreme breadth is	22.6998	
The height of the wing-transom is 24 feet, which produces for every 2½ inches	5	
	<hr style="width: 50%; margin: 0 auto;"/>	
	27.6998	27.6998
Length of the keel for tonnage	131.3	
Multiplied by the extreme breadth	37.8333	
	<hr style="width: 50%; margin: 0 auto;"/>	
Multiplied by half the extreme breadth	4967.5122	18.9166
	<hr style="width: 50%; margin: 0 auto;"/>	
Divided by 94	93968.	
Burthen in tons, according to the common rule	999½	

Estimate, shewing the real burthen of the East India ship, Plate XII.

	Tons.	lbs.	
The weight of the ship at the launching draught of water	748	1071	
The weight of the furniture, including the sheathing	62	1782	
	<hr style="width: 50%; margin: 0 auto;"/>		
The weight of the ship at her light water-mark	811	613	
	<hr style="width: 50%; margin: 0 auto;"/>		
The weight of the ship at her load water-mark	2029	597	
From which deduct her weight at the light water-mark	811	613	
	<hr style="width: 50%; margin: 0 auto;"/>		
Real burthen	1217	2224	
Burthen in tons, according to the common rule, as above	999	1477	
	<hr style="width: 50%; margin: 0 auto;"/>		
Difference	218	747	

We now find that the East India ship will carry 218 tons 747 lbs. more than she is rated for by the common rule; which, it plainly appears, is in consequence of her body being formed so full; and the greater the contrast between full and sharp bodies, the greater will be the error in the tonnage cast by this rule; which shews the impropriety of the erroneous method practised for casting a ship's tonnage.

Hence it is obvious, that no dependence can be placed on the common rules for ascertaining the true tonnage of vessels. Indeed we neither have, nor expect to have, any rule that shall be quite exact; because the tonnage depends not only upon the cubical dimensions of the ship's bottom, but also on the weight and caulking of her

whole frame. For instance, a ship built at Archangel of fir, will carry considerably more than another of the same plan in every respect, built at the Havannah of live oak; nor is there a greater difference in some ships, when the weight of every thing which properly makes a part of the ship, as to the fastening, &c. &c. is considered. We must, therefore, be contented with a rule that approximates nearer to the truth; and such is the following, proposed by the late Mr. Parkyns, of Chatham-yard.

Rule 1. For sharp ships, particularly those of the royal navy.

1st. Take the length on the gun-deck, from the rabbet of the stem to the rabbet of the stern-post, or between the perpendiculars. Then take ¾ths of this length, and call it the *keel for tonnage*.

2dly. To the extreme breadth add the length of the gun-deck, or length between the perpendiculars. Then take ⅓d of this sum, and call it the *depth for tonnage*.

3dly. Set up this depth from the limber-strake; and, at that height, take a breadth also from out to outside of the plank at dead-flat, and another breadth between that and the limber-strake: add together the extreme breadth and these two breadths. Take one-third of the sum, and call it the *breadth for tonnage*.

Lastly. Multiply the length for tonnage by the depth for tonnage, and the product by the breadth for tonnage, and divide by 49. The quotient will be the burthen in tons nearly.

The following trials have been made, to prove the accuracy of this rule.

Ships' Names.	Guns.	Tonnage by the King's or common Rule.	Tonnage by Mr. Parkyns's Rule.	Tonnage actually received on board.
Victory -	100	2162	1839	1840
London -	90	1845	1575	1677
Arrogant -	74	1614	1308	1314
Diadem -	64	1369	1141	965
Adamant -	50	1044	870	886
Dolphin -	44	879	737	758
Amphion -	32	667	554	549
Daphne -	20	429	329	374

Rule 2. For ships of burthen, or commercial ships in general.

1st. Take the length of the lower deck, from the rabbet of the stem to the rabbet of the stern-post. Then take ¾ths of this length, and call it the *keel for tonnage*.

2dly. To the extreme breadth add the length of the lower deck. Then take ⅓ths of the sum, and call it the *depth for tonnage*.

3dly. Set up this depth from the limber-strake; and, at that height, take a breadth also from out to outside of the plank at dead-flat; take another at two-thirds of this height, and another at one-third of the height: add the extreme breadth and these three breadths together, and take one-fourth of the sum for the *breadth for tonnage*.

Lastly. Multiply the length for tonnage by the depth for tonnage, and the product by the breadth for tonnage, and divide by 36.6666 or 36⅔; and the quotient will be the burthen in tons.

The following trials, among many others, shew that this rule does not deviate much from the truth.

## SHIP-BUILDING.

	Tonnage by the King's or common Rule.	Tonnage by Mr. Parkyn's Rule.	Tonnage actually received on board.
Granby, East India } ship - - - }	786	1179	1179
Northington, do. -	676	1053	1064
Union, a collier -	193	266	289
Friends Goodwill, do.	182	254	277

The general rule for calculating the loading of colliers is as follows:

From the length of the keel subtract 6 or 7 feet for the dead stowage fore and aft; multiply the remainder by the breadth at the midship-frame, and that product by the depth of water the ship draws when loaded; divide this by 96, and you will have the number of London chaldrons the ship will carry.

*A method of constructing a scale of solidity, by which may be ascertained the quantity of water displaced at any given draught, and the weight required to bring the ship down to any draught of water proposed.*

In order to construct this scale for any ship, it is requisite, in the first instance, to calculate the quantity of water displaced by the bottom, below each water-line, and by the keel, in the same manner that we have already done for the 74-gun ship (Plate I.); for which ship, as the areas of the several water-lines are already calculated, a scale of solidity may be readily constructed as follows:

Construct a scale of equal parts, to represent tons, as the scale so marked in Plate XIV.; and another to represent feet and inches, as that below it. The larger these scales, the more exact will be the performance.

Water-Lines, &c.	Height.	Water displaced in	
	Feet.	Cubic Feet.	Tons.    Lbs.
Keel and false keel - - - -	2.0 = C	531.5	15    615
Between the keel and first water-line - - - -	3.6	7254.881	208   1113
Sum - - - -	5.6 = D	7786.381	223   1728
Between the first and second water-lines - - - -	3.6	15992.156	459   1335
Sum - - - -	9.2 = E	23778.537	683   823
Between the second and third water-lines - - - -	3.6	20345.850	584   1604
Sum - - - -	12.8 = F	44124.387	1268   187
Between the third and fourth water-lines - - - -	3.6	23824.350	684   1532
Sum - - - -	16.4 = G	67948.737	1952   1719
Between the fourth and fifth water-lines - - - -	3.6	26593.425	764   592
Sum - - - -	20.0 = H	94542.162	2717   71

Now set off the tonnages from the above table upon the corresponding water-lines, &c. in Plate XIV. fig. 1, thus: upon C, representing the upper side of the keel, set off, from the perpendicular A H, 15 tons 615 lbs., taken from the scale of tons, equal to Cc. Upon the line D, or lower water-line, set off 223 tons, 1728 lbs. equal to Dd. Upon the line E, or second water-line, set off 683 tons 823 lbs. equal to Ee. In like manner, set off the other tonnages upon their corresponding water-lines: then through the points Cc, Dd, Ee, Ff, Gg, Hh, draw the curve A S, which will represent the solidity of displacement at any given height.

Draw the line A B, representing the lower side of the keel; and at A square up a perpendicular. Then set up from A B, the depth of the keel and false keel from the sheer-draught, Plate I.; likewise all the water-lines, D, E, F, G, H, as shewn in Plate XIV. fig. 1, parallel from the line A B.

The following table is formed by the preceding calculations.

Thus, the first column is obtained merely by first inserting the depth of the keel and false keel, and adding, successively, the distance each water-line is apart.

The second column is obtained by first taking, from the foregoing calculations, the cubical contents of the keel and false keel, which is 531.5 feet, as shewn in the table at C.

Then find the cubical contents between the upper side of the keel and lower water-line, by finding the mean area, and multiplying it by the distance of the water-line above the keel, which is 3.6 feet, and we have 7254.881, the displacement between the lower water-line and the keel: add this number to the former, and the whole will be 7786.381, the displacement at the lower water-line, or D.

Again, find the mean area of the first and second water-lines 4442.2655, and multiply it by the distance between the water-lines (3.6 feet), and add the product to the former. The sum will be 23778.537, the displacement at the second water-line, or E.

In like manner, find the mean area of the second and third water-lines, and multiply it by the distance between. Add the product to the former, and it will produce 44124.387, the displacement at the third water-line, or F. Thus proceed with the rest.

The third column is to be filled up by multiplying each line of the second column by the weight of a cubical foot of sea-water (64½ lbs.), and dividing the product by 2240, the number of pounds in a ton; which will, of course, give the weight in tons and pounds, as in the table.

For example, the 74 (Plate I.) draught of water, when launched, was 13 feet forward and 17 feet abaft; which gives 14 feet 3 inches at dead-flat, or midships, the ship's chief support in this light state. Take, therefore, 14 feet 3 inches from the scale of feet, and set it up parallel from the line A B, or lower side of the keel, to intersect the curve of displacement, as at Ii. Take the nearest distance from the intersection of the curve to the perpendicular A H, and apply it on the scale of tons, and it gives 1550 tons 1120 lbs. But by the estimate, the weight of the ship, at her launching draught of water, was 1377 tons 2198 lbs., which exceeds the above by 172 tons 1162 lbs.; but that may

## SHIP-BUILDING.

may be easily accounted for, by the weight of anchors, cables, men, ballast, &c. as additional weight in the ship at that time. Take 1377 tons 2198 lbs., the weight of the hull exclusively, from the scale of tons, and set it off from the perpendicular line  $AH$ , along the line  $AB$ , or base; whence square up the perpendicular  $Kk$ , to intersect the curve of displacement. That depth we find by the scale of feet to be 13 feet 4 inches, a difference of 11 inches, accounted for as above.

Now to prove the real burthen of the ship by this scale of displacement, we have found, by the estimate, that the ship, with her furniture, &c. displaces 1582 tons 998 lbs. at her light water-mark. Take 1582 tons 998 lbs. from the scale of tons, set it off as before, and raise the perpendicular  $Ll$  to intersect the curve of displacement; and another perpendicular at 2829 tons 175 lbs., taken from the scale of tons, which is the weight of the ship at her load water-line, as  $Ll$ . Then take the distance between the two perpendiculars last drawn, and apply it on the tonnage scale, and we have 1247 tons nearly, the real burthen, as before shewn by calculation.

Again, take the height where the perpendicular  $Ll$  intersects the curve of displacement, and apply it on the scale of feet, and we have 20 feet 6 inches, the medium height of the load draught of water, which was 20 feet forward, and 21 feet abaft.

Now the perpendicular  $L$  being the utmost limit of the quantity of water, expressed in tons, displaced by the bottom of the ship, when she is brought down to her load water-line, it is evident, from what has been already said, that if the number of cubic feet of water which the ship displaces, when light, or, which is the same, the number of cubic feet below the light water-line, be subtracted from the number of cubic feet contained in the bottom, below the load water-line, the quotient will be the real burthen or tonnage.

Any other case to which this scale may be applied is obvious, particularly to merchant-ships. Let it be required to find the number of cubic feet displaced, when the draught of water is 17 feet 7 inches, and the additional number of tons required to bring the ship down to her load water-line.

Take 17 feet 7 inches from the scale of feet, and set it up upon the perpendiculars  $AN$  and  $Ll$ , above the base line  $AB$ , and draw an horizontal line through those spots, intersecting the curve of displacement at  $o$ ; from thence drop the perpendicular  $Oo$ . Take the distance  $o$ , in the horizontal line, to the perpendicular  $AN$ , and apply it on the tonnage scale, it will measure 2205 tons 1706 lbs., the displacement answerable to that draught of water; and the measurement from  $o$ , taken to the perpendicular  $Ll$ , applied on the tonnage scale, will give 623 tons 708 lbs., the additional weight necessary to bring the ship down to the load water-line. Again, 623 tons 708 lbs. added to 1582 tons 998 lbs., give 2205 tons 1706 lbs., as above, and thus it is proved that the perpendicular  $Oo$  is equally distant from the perpendiculars  $Mm$  and  $Ll$ .

The measurement of the tonnage might be facilitated, by drawing the tonnage scale reversed on the base line  $AB$ , and at the load water-line, as in the plate.

Now if the draught of water be required, corresponding to any weight intended to be put on board, it may be readily known as follows.

Find the given number of tons, suppose 928, in the scale on the line  $ml$ , through which drop a perpendicular to intersect the curve of displacement, as at  $Pp$ ; and at  $p$  draw an horizontal line. Now the perpendicular distance

between the base line  $AB$ , and intersection of  $p$ , being applied on the scale of feet, will give 19 feet, the draught of water required.

Many useful discoveries may be made by blocks or models of ships, and with as great certainty as by the nicest calculations; for it must be allowed, as before observed, that in calculating from a draught drawn from a quarter of an inch scale, it will be liable to some inaccuracies, which cannot be obviated in practice, by reason of various little alterations which may be made in laying off the ship in the mould-loft; consequently the draught and the ship will, in those points, disagree. And likewise, upon strict examination, we shall be enabled to find, that there are not many ships that have both their sides exactly equal in every respect.

Let the block, or model, be constructed to a scale of one-quarter of an inch to a foot of the corresponding parts on the ship; and care should be taken to provide the wood as light and dry as possible.

The model being accurately constructed, it may be also proved by suspending it by a line, fastened to a hook in any part of a straight line, drawn from the middle line of the stem to that of the stern-post. This hook may be moved forward and aft to different places in the middle line, and a weight may be suspended from the upper part of the middle line, on the post. If the two sides be exactly of equal dimensions, and homogeneous, they will then be of equal weight. A plane passing through these three lines, whatever part of the middle line the hook be in, will likewise pass through the middle line of the keel, stem, and post: therefore, if the model stands this proof, it will be as true to work from, as the nicest calculations.

The model, having stood this test, may be suspended by the same line, or silk, in different positions, until it points out the centre of gravity; which will be found, when the block hangs in a state of equilibrium. This practice is, doubtless, very simple; but it will be found very convenient. Further, the model being suspended by the hook, the lines hanging at the stem and post corresponding to their middle lines, and to that which suspends the block, we may hold a batten out of winding with the line that suspends it, and, with a pencil, draw a line upon it. A plane passing through this pencil line, at right angles to the keel, and passing likewise through the line that suspends the block, will likewise pass through the centre of gravity, which, therefore, must be somewhere in this plane. Again, move the hook to some other part of the middle line, and let the block be suspended from that point; draw also another pencil line, out of winding with this last line of suspension, and the intersection of the two lines will give the height of the centre of gravity above the keel, and likewise its distance from the post and stem; and if the hook be moved to any other part of the middle line, and a pencil line be drawn as before, it will likewise intersect in the same point; or, let there be ever so many points assumed in the middle line, and the block suspended by each, and pencil lines drawn, they will all intersect in the same point; and as the centre of gravity will always be in that plane which passes through the middle line of the keel, stem, and post, it may with certainty be marked on the draught.

This will certainly require the greatest nicety; but, if well executed, it will agree with that found by calculation, provided the dimensions be taken very exactly, and likewise from a true scale of equal parts.

By the same model may be found the true tonnage of a ship, thus: Let the light and load water-lines be marked on it; then put the model in water, and load it until the surface

## SHIP-BUILDING.

face of the water is exactly at the light water-line; and let it be suspended until the water drains off, and then weighed. Now, since the weights of similar bodies are in a triplicate ratio, or as the cubes of their homologous dimensions, the weight of the ship, when light, is, therefore, equal to the product of the cube of the number of times the ship exceeds its model by the weight of the model, which is to be reduced to tons. Hence, if the model is constructed to a quarter of an inch scale, multiply the weight of the model by the cube of 48, (one-fourth of an inch being equal to  $\frac{1}{4}$ th of a foot,) or 110592, which will give the weight of the ship. If the multiplier be ounces, the product will be ounces; if pounds, it will be pounds: and it is to be reduced to tons accordingly.

*Example.*—Suppose the weight of a model of the 74 (Plate I.) to be 32 lbs. 13 drachms, when brought down to the light water-line.

The cube of 48	110592		
Multiplying by -	32 lbs. 13 drachms		
Produces -	3544560 lbs. = 1582 tons 880 lbs.		

The weight of the ship at her light water-mark, within 118 lbs.

Again, let the model be loaded, until the surface of the water is exactly at the load water-line. Now the model being weighed, the weight of the ship is to be found by the preceding rule; then the difference between the weights of the ship, when light and loaded, is the tonnage required.

### *Upon the Efforts of the Water to bend the Vessel.*

Here we can do no better than quote Watson's translation of Euler upon the *Théorie, &c. des Vaisseaux*; to which book we refer our readers for a further illustration of the foregoing particulars, and to Atwood on the Stability of Vessels.

“When we say, that the pressure of the water upon the immersed part of a vessel counterbalances its weight, we suppose that the different parts of a vessel are so closely connected together, that the forces which act upon its surface are not capable of producing any change; for we easily conceive, if the connection of the parts was not sufficiently strong, the vessel would run the risk either of being broken in pieces, or of suffering some alteration in its figure.

“The vessel is in a situation similar to that of a rod *AB* (Plate XIV. *fig. 2.*), which, being acted upon by the forces *Aa*, *Cc*, *Dd*, *Bb*, may be maintained in equilibrium, provided it has a sufficient degree of stiffness; but as soon as it begins to give way, we see that it must bend in a convex manner, since its middle would obey the forces *Cc* and *Dd*, whilst its extremities would be actually drawn downwards by the forces *Aa* and *Bb*.

“The vessel is generally found in such a situation; and since similar efforts continually act, whilst the vessel is immersed in the water, it happens but too often that the keel experiences the bad effect of a strain. It is, therefore, very important to inquire into the true cause of the accident.

“For this purpose, let us conceive the vessel divided into two parts, by a transverse section through the vertical axis of the vessel, in which both the centre of gravity, *G*, of the whole vessel, and that of the immersed part *O*, are situated; so that one of them will represent the head part, and the other that of the stern; each of which we shall consider separately. Let *g* be, therefore, the centre of gravity of the entire weight of the first, and *o* that of the immersed part corresponding. In the same manner, let *y* be the centre of

gravity of the whole stern part, and *w* that of its immediate portion.

“Now it is plain that the head will be acted upon by the two forces *gm* and *on*, of which the first will press it down, and the latter push it up. In the same manner, the stern will be pressed down by the force *yu*, and pushed up by the force *wx*: but these four forces will maintain themselves in equilibrium, as well as the total forces reunited in the points *G* and *O*, which are equivalent to them; but whilst neither the forces before nor those abaft fall in the same direction, the vessel will evidently sustain efforts tending to bend the keel upwards” (called *hogging*) “if the two points *o*, *w*, are nearer the middle than the two other forces *gm* and *yu*. A contrary effect would happen if the points *o* and *w* were more distant from the middle than from the points *g* and *y*,” called *sagging*.

“But the first of these two cases usually takes place in almost all vessels; since their hollow has a greater breadth towards the middle, and becomes more and more narrow towards the extremities; whilst the weight of the vessel is, in proportion, much more considerable towards the extremities than at the middle. From whence we see, that the greater this difference becomes, the more also will the vessel be subject to the forces which tend to bend its keel upwards; it is, therefore, from thence that we must judge how much strength it is necessary to give to this part of the vessel, in order to avoid such a consequence.

“If other circumstances would permit, either to load the vessel more in the middle, or to give to the part immersed a greater hollow towards the head and stern, such an effect would no longer be feared; but the destination of most vessels is entirely opposite to such an arrangement; by which means we are obliged to strengthen the keel as much as may be necessary, in order to avoid such a disaster.”

Having now investigated the centre of gravity of the displacement, meta-centre, and centre of gravity of the whole ship, with other particulars, and laid down all that is requisite to be attended to, in that respect, for the construction of a ship's body under water, we shall, in the next section, proceed to complete the remainder of the sheer-draught.

### *To complete the Construction of the Sheer-draught. Plate I.*

Having found that the displacement of the ship at the load-water-line gives the ship sufficient stability to keep the lower ports 5 feet 10 inches above the water, we may proceed to draw all the decks in the sheer-plan, beginning with the lower, or gun-deck. The height of the lower fills of the gun-deck ports should be 2 feet 4 inches above the gun-deck plank, which is four inches thick; consequently the upper side of the beam along the side must be 2 feet 8 inches below the fills; add six inches to that for the round-up of the beam; and the under side of the gun-deck at the middle line in midships will be 22 feet 2 inches above the upper edge of the keel; at the foremost-perpendicular set up 24 feet, and at the after-perpendicular 24 feet 8 inches; then a segment of a circle drawn through these three heights will represent the under side of the gun-deck at the middle line. (These kinds of sweeps are drawn by thin veneers of pear-tree wood, called sweep-moulds, struck from a long radius on purpose, or by a drawing-bow.) Now set up four inches, and the thickness of the gun-deck plank, above the line last drawn, and let another line be drawn parallel thereto, and the gun-deck will be described at the middle line in the sheer-plan.

Next proceed to draw the upper deck; set up 7 feet 2 inches, being the height from the upper side of the gun-deck plank to the under side of the upper deck plank, along the

## SHIP-BUILDING.

the middle line, through which heights draw a curve parallel to the gun-deck, and another curve three inches parallel above it, and the upper deck will be represented at the middle line of the sheer-plan.

The stern-timbers should be next drawn, to shew the boundaries of the sheer-plan above the wing-transom. Set up above an horizontal line drawn at the upper side of the wing-transom at the middle line four feet, upon a perpendicular 6 feet 10 inches abaft the aft-side of the wing-transom, which will be the height and knuckle of the lower counter at the middle line; from thence draw a curve, about six inches hollow, to the upper side of the wing-transom, where the fore part of the rabbet of the stern-post intersects it; and that curve will represent the lower counter at the middle line.

In the same manner, set up the height of the upper counter 7 feet 5 inches, upon a perpendicular nine feet abaft the aft-side of the wing-transom, which will be the height and knuckle of the upper counter at the middle line; then drawing a curve about one inch hollow from thence to the knuckle of the lower counter, the upper counter will likewise be described at the middle line.

Having the upper and lower counters drawn at the middle line, the upper part of the stern-timber is straight above the upper counter, and must be drawn as follows:

Set up 23 feet 8 inches, upon a perpendicular 14 feet abaft the aft-side of the wing-transom, as before, and then drawing a straight line from the knuckle of the upper counter, to pass through the said spot, the upper part of the stern-timber will be shewn at the middle line, by which the rake of the stern will be described.

As the stern rounds two ways, both up and aft, (or forward from the timber already drawn,) the stern-timber at the side must alter so much from that at the middle line, and therefore remains to be represented. Set down from the knuckle of the upper counter on its perpendicular 9 inches, and draw an horizontal line before it at that place, and set off thereon 15 inches from the said perpendicular, which will be the knuckle of the upper counter at the side the 9 inches is the round-up, and the 16 inches the round-aft at the upper counter. Then proceed in like manner for the lower counter, by setting down 9 inches, and forward 15 inches, and the knuckle for the lower counter at the side will be produced; then, by drawing a curve from the knuckles at the side (similar to the curve or hollow at the middle line), observing the lower counter at the side is drawn to intersect the touch of the wing-transom at the side, the side stern-timber only wants the upper part to complete it. But as the straight line, which remains to be drawn for the upper part of the side-timber, should not be parallel to that at the middle line, the following method will determine the exact rake thereof.

Draw a straight line at pleasure, as the ticked line under the body-plan, on which set off the breadth of the stern at the upper counter, or 13 feet 4 inches, equally on each side of the middle line; and there square up a perpendicular on each side: set up from the straight line 16 inches, the round-aft of the upper counter on each perpendicular, and draw a segment of a circle that shall intersect those spots and the straight line at the middle, and the round-aft of the stern will be described at any part of the breadth above the upper counter: thus, take the breadth of the stern at the top timber-line, which is 24 feet 8 inches above the wing-transom, which is 24 feet, and set it off equally on each side the middle, to where it shall intersect the round-aft under the body-plan; thence draw a line parallel to that first drawn, and the distance between the two lines,  $13\frac{1}{2}$  inches, is the

distance that the side-timber will be from the middle-timber: on an horizontal line, at the height of the top timber-line, draw a straight line through the last spot set off to intersect the knuckle of the upper counter at the side, and that will be the rake of the side counter-timber, as shewn by the ticked lines in the sheer-plan, *Plate I.*

The rake of the stern-timbers being determined, proceed to finish the decks. Set up from the upper side of the upper deck 6 feet 10 inches at the middle stern-timber, and 6 feet 8 inches fore part at frame 8, and above that 3 inches, drawing curves as before, and the quarter-deck at the middle line will be represented.

Proceed in the same manner with the round-house abaft. Set up from the upper side of the quarter-deck 6 feet 8 inches at the middle stern-timber, and 6 feet 6 inches at fore part or frame 24, and above that  $2\frac{1}{2}$  inches. The forecastle forward is represented in the same way, by drawing curves, one parallel to the upper side of the upper deck 6 feet 7 inches above it, and another at 3 inches from the beak-head to frame D.

All the decks having been drawn, representing their heights at the middle line, their heights at the sides differ from the former, agreeable to the round of the beam in the breadth of the ship: to do which correctly, take the round-up of the beam of its respective deck, say the gun-deck, 6 inches, and set it up in the middle of any straight line, so that the half-breadth in midships at the height of the gun-deck may be set off on each side on the line. Then raise the segment of a circle that shall intersect the round-up at the middle, with the spots at the breadth, and the round-up of the deck will be described at any part of its breadth. Thus, take the half-breadth at the height of the deck at any timber in the body-plan, and set it off equally from the middle of the round-up till it intersects the curve; whence draw a line parallel to that first drawn, and the distance between the last line to the round-up in the middle is what the beam rounds at that place: thus may the round-up be taken at as many timbers as may be found necessary, and set below the under side of the deck, at its respective timber in the sheer-plan; then a curved line passing through those spots, will represent the deck at the side: but observe, that the decks are to have a sufficient round abaft, to correspond with the round-up of the stern above the lights, and that the additional round wanted to be set down at the side line.

The sheer or top timber-line may be next drawn, by setting up its height in the sheer-plan afore in midships, and abaft: thus, at timber X forwards, 37 feet 8 inches; at  $\ominus$  in midships, 35 feet 4 inches; and at the side stern-timber abaft, 41 feet 6 inches: then, by drawing a curve through these spots, as in *Plate I.* the sheer of the ship, or top-timber line, will be represented.

The ports may now be drawn in the sheer-plan, thus: draw two curves in pencil parallel to the deck at the side, fore and aft, adding the thickness of the deck to that already drawn, as that represents the under side of the deck, or upper side of the beam. The gun-deck ports are to be 2 feet 4 inches from the upper side of the gun-deck plank to the upper side of the lower fills, 2 feet 8 inches deep, and 3 feet 5 inches fore and aft, or from the fore to the after sides, which may now be squared up between the lines last drawn; placing the fore-side of the foremost port 1 foot 5 inches abaft timber X, and 3 feet 1 inch only on athwart-ship line; the aft-side of the after-port to be 14 inches afore timber 32, and the fore-side 3 feet 5 inches afore it, or in the clear; and the remaining 13 to be 7 feet 7 inches asunder. In the same manner draw in the upper deck ports, which

## SHIP-BUILDING.

which are from the plank to the port-fill 1 foot 11 inches, 2 feet 8 inches deep, and fore and aft 3 feet; and are to be placed equally between and over the gun-deck ports, as circumstances will admit, as shewn in the sheer-plan, *Plate I*. The ports on the quarter-deck, round-houfe, and forecattle, must be placed hereafter where there is a vacancy between the dead-eyes to admit of them, observing to place them as nearly as possible at equal distances.

To know the heights, round-up, &c. &c. of the other decks, take them with compasses, in like manner as the gun-deck was set off from the given dimensions; and by applying them to the scale of feet, much repetition will be avoided.

The round-houfe deck being drawn, draw a line parallel to the top timber-line, and another line three inches above it, which is of the thickness of the plank-sheer, corresponding with the fore part of the round-houfe, so as to make both plank-sheer and water-way; so will the extreme height of the top-side be described abaft: the plank-sheer, which completes the height of the side to the fore part of the quarter-deck, is four feet four inches to the under side above the top timber-line, and parallel thereto. The fore part abreast the main-mast hances down eleven inches for seven feet abaft the gangway or fore part of the quarter-deck.

The drift-rail may now be drawn, the under side of which is two feet ten inches above the top timber-line, and parallel thereto from the hance of the plank-sheer at the main-mast to the quarter-gallery. The drift-rail is four and a half inches deep, and drawn parallel to the under side last drawn, and hances as the plank-sheer abreast the main-mast, and tops with a scroll upon the sheer-rail at the gangway. The sheer-rail may next be drawn: it is six inches deep, and parallel to the top timber-line from the cat-head to the quarter-gallery. The plank-sheer and sheer-rail at the fore part of the ship delineate the height of the top-side there: the under side of the plank-sheer is two feet nine inches above the top timber-line, and the under side of the drift-rail one foot eight inches, and turns off with scrolls at the after part of the forecattle, but in other respects the same as those at the quarter-deck.

It is the practice in the navy of late years, to have square drifts instead of scrolls or hances of any kind.

The upper part of the ship being thus far complete, we have at one view the utmost extent of the sheer, as seen on a plane.

It now remains to be drawn in the finishing parts, as the wales, stern, head, rails, &c.

Proceed to represent the main wales by setting up their lower edge, at the rabbet of the stem or fore part, above the upper edge of the keel 22 feet 6 inches, in midship or dead-flat 18 feet 8 inches, and at timber 34, 23 feet, and draw the curve as in sheer-plan, *Plate I*. Above that, and parallel thereto, draw another curve at 4 feet 4 inches, the breadth of the main wales.

Next draw in the channel wales, set up as before, at the rabbet of the stem 30 feet 2 inches, in midships 27 feet 3 inches, and at timber 34, 31 feet 6 inches. Set up their breadth 3 feet, and draw curves as in sheer-plan, *Plate I*.

The waist-rail may be next drawn: its distance below the top timber-line is one foot ten inches, the upper side and its depth six inches, and it is drawn parallel to the top-timber line all fore and aft.

Now, before the channels and dead-eyes can be drawn, the centres and raking of the masts must be determined; their centres on the gun-deck being fixed upon in proportion to the length of the gun-deck, thus: the centre of the fore-mast is 21 feet 4 inches abaft the aft-side of the stem, or half its diameter before the one-ninth of the length on the

gun-deck: the centre of the main-mast 101 feet 4 inches abaft the aft-side of the stem, or half its diameter abaft the five-ninths of the length of the gun-deck: and the centre of the mizen-mast 27 feet before the rabbet of the stern-post, or half its diameter before the one-seventh of the length of the gun-deck. The centre being fixed, the fore-mast rakes aft (or inclines from a perpendicular with the keel) one-eighth of an inch in every yard of its length; the main-mast rakes aft one inch in every yard in the length; and the mizen-mast one inch and a half in every yard of its length, as drawn in the sheer-plan, *Plate I*.

Now draw the channels, placing their upper edges next the side in a line with the upper edge of the sheer-rail; or, which is much better, since the rails on the side are discontinued, rather lower down, clear of the seam. The fore channel to be 36 feet long, and so placed as to take the anchor-lining and bill-board for stowing the anchor at its fore end, thus: get the length of the anchor to the bill, or extent of the arm, and allow for the cat-block; then with that distance sweep upwards from the channel-wale to the channel, from the outer end of the cat-head nearly, and the curve that the bill of the anchor is supposed to make, will give the middle of the lining: the aft-side from the channel may be perpendicular, and the fore part follow the curve made by the anchor. The bill-board may then be carried upwards from the upper side of the channel to the top of the side. The anchor-lining commences at the upper side of the bollster, which rests on the channel-wale, and is long enough at the fore part for a man to stand upon.

The main channel is 29 feet 6 inches long, placed in the same range as the fore channel, and its fore-end before the centre of the mast about six inches.

The mizen channel is 16 feet 4 inches long, placed like the former, but is more convenient when placed, as it now is, above the quarter-deck ports.

The dead-eyes may now be drawn, observing to place them in such a manner that the chains may be sufficiently clear of the ports. All the preventer-plates must be so placed on the channel-wales, and of such a length, that the centre of the chain-bolt may come about six inches below the upper edge, and the preventer-bolt about four inches above the lower edge of the channel-wales. The dead-eyes in the main and fore channels are sixteen inches in diameter, and eleven in number in the fore and twelve in the main, though lately another is added in each. In the mizen are seven, of eleven inches diameter; the centre of the foremast dead-eye is placed at or just abaft the centre of the mast, and the centres of the others are spaced so as to clear each other about three inches, which will admit of four dead-eyes between each port. It must also be observed to give each of the chain and preventer-plates a proper rake; that is, to let them range in the direction of the shrouds; which may be done in the following manner: draw a pencil line upwards at the centre of each mast, upon which let off its length to the lower part of the head; then, by drawing straight lines from that height, through the centre of each dead-eye, the direction of each chain will be obtained by the direction of its corresponding line. The dead-eyes for the back-lays are so similar to the former, that it need only be observed, that for the raking of them, the height of the top-mast to its head must be added to the lower mast, and that they are fixed at the after-end of the channel, or on floor, if need be, above the channels, as in sheer-plan, *Plate I*.

The quarter-deck and forecattle ports can now be determined, as they must be placed clear of the shrouds, and equally astunder, or nearly so, as circumstances will admit: thus, there are three on each side on the forecattle, made

## SHIP-BUILDING.

by the timber-heads there shewn, having also a timber-head between. But the practice now is to have a rail upon the heads of the timbers, and the sides birthed up on each side to the under side of the rail between the ports, and only three or four timber-heads run up, one in particular before the bill-board for the shank-painter. On the quarter-deck are seven ports of a side, and four on the round-house, placed as clear as possible of the shrouds, as shewn in sheer-plan, *Plate I.*

The chest-tree for hauling home the main-tack must be placed near the after-end of the fore channel, or half the length of the main-yard before the centre of the main-mast, and drawn from the top of the side down to the upper edge of the channel-wale.

The steps on the side may next be drawn: they must be placed at the fore part of the main drift or gangway, about three feet in length, six inches afunder in the clear, and five inches deep: the upper step to be eleven inches from the top of the side, continuing the others to the upper edge of the wale.

To complete the sheer-plan, the head and stern only remain to be drawn, which are as useful as ornamental. Therefore we will proceed with the head, thus: draw the beak-head or its boundary aft, by raising a perpendicular six feet abaft the aft-side of the stem, at one foot eleven inches above the deck at the side, or draw an horizontal line at the same height as the upper deck port-fills: the horizontal is the flat of the beak-head, and the perpendicular continued up to the rail above the fore-castle, represents the fore part of the beak-head, and will likewise determine the foremost end of the fore-castle. Since *Plate I.* has been engraved, the beak-head in the navy seems to be done away, and the bow continued to the top of the side, as in the East India ship, *Plate XII.* It may be stronger thus, but the beak-head was very useful. Let 15 feet 6 inches, the length of the head, be set off from the fore part of the stem, and there draw a perpendicular which will determine the fore part of the block or figure; draw another perpendicular at 3 feet 10 inches abaft the former, which is the moulded breadth of the figure, and boundary of the hair-bracket at the upper part. Before the height of the figure can be ascertained, the bowsprit must be drawn, thus: set up 4 feet 6 inches at the aft-side of the stem, above the upper deck, for its middle line, and raise that line 5 inches or  $5\frac{1}{2}$  inches above an horizontal in every foot forward; then set off 1 foot  $5\frac{1}{2}$  inches above and below this middle line, and draw lines parallel thereto, and the bowsprit will be represented in the sheer-plan, *Plate I.* Now the upper part of the block for the figure can be determined, as that should be at least six inches clear of the under side of the bowsprit, which should pass the under side of the foremost upper deck beam, and step in the partners on the gun-deck a convenient height for the after part of the manger, as in the inboard works, *Plate IV.* of *Ship-building.*

The cheeks are next to be drawn: set up the height of the lower cheek at the stem, which is 25 feet at its under side, above the rabbet of the keel, and draw the after-end to the sheer, and the fore part with a handsome slight, so as to break in with the perpendicular at the fore part of the figure; then set up from the under side of the lower cheek, 3 feet 5 inches at the stem for the under side of the upper cheek; draw the after-end rather more than the sheer, and the fore part with more slight than the lower cheek, so as to make a handsome curve line with the fore part of the hair-bracket. From the under side of the lower cheek, set up at the fore part of the stem 7 feet 11 inches, which is the upper side of the upper rail, and draw the bag of it, or the part

immediately before the stem, nearly horizontal, or to the sheer of the flat of the beak-head, it agreeing to that height. The fore-end should curve upwards, so as to appear parallel with the upper cheek, or nearly so; and to form the after-end, draw a curve from the bag to break in fair with the beak-head line.

Now the moulding of the upper rail and siding of the cheeks may be drawn, and as they taper all their length regularly, set off 1 foot above the lower side at the after-end of the cheeks, which is 5 feet abaft the fore-side of the stem on the sheer, and 7 inches at the fore-end, or about 8 feet 6 inches before the stem. Then the moulding of the upper head-rail, which is 1 foot, must be set off abaft the beak-head line, or fore-side of the rail, and drawn parallel thereto from about 5 feet below its head, (which must range with the under side of the rail above the fore-castle, or six inches higher than the range of the other timber-heads,) and from thence to taper to six inches at the fore-end, which comes to the hair-bracket, which is a continuation of the upper cheek, and runs in a handsome serpentine line up the back of the figure, as high as where the shoulder of the figure is supposed to come; at which place it terminates with a scroll. The upper part of the figure or block is formed, by continuing the line from the breast or fore part of the figure to the top of the hair-bracket, observing to keep the upper part six inches clear of the under side of the bowsprit, as before observed.

The head-timbers may now be drawn, placing the stem-timber its thickness, which is 7 inches, before the stem, and to stand perpendicular from the upper side of the lower cheek to the under side of the upper rail. The foremost timber to be 8 feet before the stem, and to stand parallel to the stem-timber, or rake half its thickness at least, which is  $2\frac{1}{2}$  inches, which will produce a lighter appearance in the head: the middle timber is placed equally between the two former, and is six inches thick. Another timber is sometimes placed abaft the stem-timber, at the same distance as the one before it, the heel of it stepping on the upper edge of the lower rail. The length of the block for the figure sometimes terminates by a perpendicular line at the heel of the foremost head-timber; the lower cheek ends there, or is continued higher up the figure, and finishes with a scroll. The hair-bracket also continues down to the heel of the figure.

The head-timbers being drawn, the middle and lower rails may be drawn by dividing the space between the upper side of the upper cheek and under side of the upper rail equally at every head-timber; then drawing curves to pass through the moulding depth of each rail, equally set off from the above spaces, which moulding depth is  $6\frac{1}{2}$  inches at the stem, and  $4\frac{1}{2}$  inches at the hair-bracket. The after-end of the lower rail may terminate where it touches the side. Before the rail above it can be finished, the cat-head must be drawn, letting it project from the aft-side of the upper part of the main or upper rail to rake forward, so as to stand square with the bow, or nearly so, and to rise upwards  $5\frac{1}{2}$  inches in every foot of its length, which is 8 feet 6 inches without the bow; observing that the under side is to lay on the plank of the fore-castle at the side: the upper side may be drawn parallel to the under side at 1 foot  $4\frac{1}{2}$  inches, its depth: the knee or supporter under the cat-head forms a fair curve to the after-end of the upper middle rail, as in sheer-draught, *Plate I.* The knee or supporter under the cat-head lately hangs perpendicularly, or nearly so, and the rail ends against the side.

The knee of the head may next be drawn; it is to project from the breast of the figure about four inches; thence draw

## SHIP-BUILDING.

draw the fore part of the knee, with an agreeable serpentine line to its breadth from the stem, which should not exceed two feet on a square at the load-water-line; then, by continuing the same line downwards, narrowing more and more till it approaches the gripe, and drawing it more distant from the stem, to about four feet in the broadest place, let the lower part break in fair with the under side of the false keel, where it terminates with the fore foot or fore part of the keel, which will be next described. The gammoning-holes come between the head-timbers, and the bobstay-holes at the fore part of the knee, and the hawse-holes between the cheeks are to be 2 feet 6 inches up from the deck, and 1 foot 3 inches in diameter, as shewn in the sheer-plan, *Plate I.* See *Hawse-holes*, hereafter described. From the line representing the upper edge of the keel, set down 1 foot 6 inches, its depth, and draw a line parallel to its upper edge the whole length, which is 1 foot 2 inches before timber S, to the aft-side of the stern-poll, and the lower edge of the keel will be represented; but to complete the fore foot, which must be of a sufficient depth to receive the lower part of the stem, called the boxing, square up the fore end of the keel from the under side to the fore-side of the stem, and from thence square it to the aft-side of the stem from its curve. The boxing, or lower part of the stem, may now be drawn: set aft from the line last squared 6 feet 6 inches, and draw a perpendicular to half the depth of the keel, and from thence continue a line forward, parallel to the lower edge of the keel, one-third the length of the scarf, which will meet the fore-side of the stem and complete it.

The false keel, which is six inches deep, may be drawn by a line parallel to the under edge of the main-keel; the fore end of it may continue about three inches before the main-keel, or run through to the fore part of the gripe.

The sheer-draught being thus far completed forward, the stern and quarters may be finished; and first draw a line which shall represent the aft-side of the quarter-piece, agreeable to the round-forward of the stem, which is 13 inches before the side stern-timber, on a square, and nearly parallel thereto, continuing this line from the plank-sheer to the lower gallery rim, the upper side of which is, at the line last drawn, 6 feet 5 inches above an horizontal line, at the upper side of the wing-transom at the middle. (Observe, all the heights of the stem will be set up above this line, for the manner of obtaining which, with every particular relative to the stem, the reader is referred to the section *Laying-off the Stern*, and *Plate X.*) At the height last set off, draw the upper side of the rim forward parallel to the sheer or top timber-line to 16 feet 6 inches, its length; then draw another line parallel under it at 10½ inches, its depth. The height of the upper side of the rail at the middle stool is 11 feet 9 inches at the quarter-piece, which must also be drawn forward parallel to the sheer to 16 feet 8 inches, its length; its depth, which is 9½ inches, draw in as the middle rim. The fore part of the quarter-piece may next be drawn, as the heel of it steps on the after end of the middle stool, by drawing a line parallel to the aft-side at 14 inches, its siding. Draw the middle rim-rail, as before directed, at 15 feet 3 inches, the height of the upper side at the fore-side of the quarter-piece, to 12 feet 2 inches, its length. In the same manner draw the upper stool-rail, its upper side being 19 feet 5 inches up at the quarter-piece, and its length forward 12 feet 8 inches. Above this rail is the upper finishing, the upper rail of which ranges with the height of the plank-sheer, with another rail below it at 9 inches in the clear: the upper rail may be about 3½ inches, and the other 4 inches. The upper rail of the finishing is 2 feet 8 inches short of

the upper stool-rail, and finishes at the fore part, as in the sheer-draught, *Plate I.* The boundary, or fore part of the upper gallery, is 11 feet 7 inches on the run of the middle rim; from thence a line is drawn upwards, parallel to the quarter-piece. Between the middle stool-rail and the rim above it, the fore part is completed by a curve. The length or boundary of the lower gallery is 15 feet 6 inches on the lower rim; from thence a line is drawn upwards, parallel to the rake of the side stern-timber. Now the lights and munions, which are three in each gallery, may be equally spaced; the lights in the lower gallery to be 2 feet 9 inches in the clear on a square, and the munions about 11 inches each; the lights in the upper gallery 2 feet 4 inches in the clear on a square, and the munions about 9½ inches each; observing to keep their lower sides up from the rail, about 5 inches the lower ones and 4 inches the upper ones for the water-table, and their upper sides about 4 inches clear of the under sides of the stool-rails above. Draw the lower stool-rail along the quarter, which is a continuation of the lower counter-rail, as the middle rim is of the upper counter-rail, at the outside of the quarter-piece, from whence they are to be continued their length parallel to the sheer, and that will be the height of those rails, as viewed on a level. The height of the lower counter-rail, at the side abaft, is 3 feet 4 inches, and from thence continued parallel to the rim-rail above: to its length, which is 13 feet, set down 10½ inches, its depth, and draw it parallel to the upper side.

The lower finishing is 2 feet 3 inches deep below the lower stool, and its boundary formed by curves, so as to have a light airy appearance, with a stool nearly in the middle of its depth.

The foot-space rail may be 9½ inches deep, and rabbets on the ends of the flat of the quarter-deck. The breast-rail is 9½ inches deep, and its upper side is 3 feet 2 inches above and parallel to the other, both projecting 2 feet 6 inches on a square to the aft-side at the middle line from the midship stern-timber. But to complete the balcony, quarter-piece, and taffrail, as shewn in the sheer-plan, the reader is again referred to laying-off the stem, and *Plate X.*

The birthing of the lower counter may be represented by drawing a curve 4 inches parallel abaft the aft-side of the counter-timbers, from the knuckle to the tuck-rail, which covers the margin on the wing-transom, and projects its thicknets 9½ inches. Draw likewise the birthing of the upper counter, which is 2½ inches thick, and parallel to the stern-timbers. Above the upper counter-rail draw in the thicknets of the middle munion, which is 3 inches, and parallel to the middle stern-timber, and continued upwards to the arch-board over the lights, which is about 4½ inches deep.

The rudder may now be represented in the sheer-plan, observing, that the head is continued above the upper deck, high enough to receive a tiller about four inches above the deck; then allow for two hoops above the hole, making the upper part of the head 2 feet 6 inches above the deck. Continue upwards the aft-side of the stern-poll, which represents the fore-side of the rudder, from whence its breadth or aft-side is set off; and as this should not be more nor less than sufficient to direct the course of the vessel, the common practice is to make the breadth at the heel, or lower end, one-eighth of the main breadth, which will be six feet for ships having a clean run abaft; but for merchant-ships, or those constructed chiefly for burthen, it may be one-seventh. The height of the lower lance may be fixed at the load-water-line, or about six inches above it, and its breadth there should be five-sevenths of the breadth at the heel.

heel, back included: set forward from thence 10 inches, or reduce the breadth to 3 feet 5 inches. The upper hance may be at one-third the height of the lower hance, and the breadth of the rudder there should be five-sevenths of the breadth at the lower hance, or 3 feet 1 inch; there reduce the breadth 5 inches, which makes it 2 feet 8 inches, from whence a straight line may be continued to the head, which is 2 feet 4 inches fore and aft, or larger, if the piece will admit of it: each hance should be reduced with mouldings, as in sheer-draught, *Plate I.*, and  $3\frac{1}{2}$  inches drawn parallel to the aft-side, to represent the thickness of the back. The heel of the rudder, at the fore part, should be 9 inches short of the under side of the false keel, and 11 inches at the aft-part, the sole included, which is 6 inches deep.

The pintles and braces may be now represented, placing the upper brace about four inches above the wing-transom, that the straps may clasp round the standard on the gun-deck. The second brace should be so placed as to fasten on the middle of the gun-deck transom. The lower brace may be placed 15 inches above the upper side of the keel, and the intermediate ones, four in number, to be equally placed between the two latter, making seven in all. The length of the braces may be governed by a straight line drawn from the third brace, which should be 4 feet 6 inches above the rabbet of the post to the lower one, which is to be six feet.

The length of all the straps of the pintles, which come upon the rudder immediately above the braces (except the thickness of the bur or saucers), may extend within four inches of the aft-side: the pintles are  $3\frac{1}{2}$  inches in diameter, and all 14 inches long, except the lower one, which is 2 inches longer. The straps of the braces and pintles are five inches broad.

The length and breadth of the rudder being represented in the sheer-plan, *Plate I.*, it is evident the breaks or hances are merely to reduce the breadth as it rises towards the head, the greatest breadth being only required below the water, where it feels the motion of the ship.

The fluid, in passing to the rudder, exactly follows the outlines of the bottom; and supposing the rudder to make an angle of 45 degrees with the keel, it may be readily seen, by the water-lines abaft in the half-breadth plan, that the immediate shock it receives from the water increases as it approaches to the load-water-line, where they become nearly at right angles with the side of the rudder in that position, and this holds good, whatever angle the rudder makes with the keel; hence some are of opinion, that the rudder should be made broader near the line of floatation, and narrower towards the keel; but the present method of making the rudder with increasing breadth downwards, is only in proportion to the obliquity of impulse the water acts against it near the keel. It must be observed, that the above force strikes the rudder obliquely, and only strikes it with that part of its motion which, according to the sine of incidence, forces it in a contrary direction, with a momentum which not only depends on the velocity of the ship's course, by which this current of water is produced, but also upon the extent of the sine of incidence. This force is by consequence composed of the square of the velocity with which the ship advances, and the square of the sine of incidence, which will necessarily be greater or smaller according to circumstances; so that if the vessel increases her velocity three or four times faster, the absolute shock of the water upon the rudder will be nine or sixteen times stronger, under the same incidence: and if the incidence is increased, it will yet be augmented in a greater proportion, because the square of the sine of incidence is more enlarged.

Amongst the several angles that the rudder makes with the keel, there is always one position more favourable than any of the others, as it more readily produces the desired effect of turning the ship, in order to change her course.

If the angle of the rudder with the keel is greater than 45 degrees, the action of the water upon the rudder will increase, and at the same time oppose the course of the ship in a greater degree; because the angle of incidence will be more open, so as to present a greater surface to the shock of the water, by opposing its passage more perpendicularly.

If, on the contrary, the angle is lessened to 30 degrees, the rudder will receive the impression of the water too obliquely, for the angle of incidence will be more acute, so that it will only present a small portion of its breadth to the shock of the water, and by consequence will only receive a feeble effort. Thus it appears, that between the effects which result from the water's absolute effort, there is one which always opposes the ship's course, and contributes less to her motion of turning, whilst the other produces only this movement of rotation, without operating to retard her velocity. Hence we may conclude, that when the water either strikes the rudder too directly, or too obliquely, it loses a great deal of the effect it ought to produce. Between the two extremes there is, therefore, a mean position, which is the most favourable to its operation, *viz.* the angle 45, or between that and 42 degrees. See *Watson's Euler*, p. 130. See also *Rudder*.

It is evident, that the fore part of the rudder, as high up as the head of the post, must be trimmed on each side, to the middle of its thickness, (which is the same thickness as the aft-side of the stern-post, or rather less, as it need not project the post when the helm is hard over,) to the greatest angle the rudder is proposed to make with the keel: however, the common method is to set off two-fifths the thickness of the rudder from the fore part on each side, and from thence trim it straight through to the middle of its thickness, or, what is better, to leave the middle to the convexity of the pintles, rather than a sharp edge. By this method the rudder may be put over to the angle of 50 degrees, which is more than is necessary, and it is very seldom that the tiller, owing to its length, can be put over so far to the side as to allow of the rudder making an angle of more than 45 degrees, which angle is quite sufficient.

When the above angle, or what is technically called the *bearding*, is wholly taken from the fore part of the rudder, the main piece is very much wounded by letting on the upper pintle; but this of late years has been greatly remedied, by taking half the bearding from the aft-side of the stern-post at the head, and from one to two inches on the heel; of course the rudder is bearded so much the less. This, also, will greatly assist the conversion of the stern-post.

The bearding on the rudder is represented by the shading on the fore part of the rudder, and the bearding on the post by the ticked line in sheer-plan, *Plate I.*

The rudder, which is represented in the sheer-draught, *Plate I.*, and is as at present used in the navy, having its axis of rotation in the centre of its pintles, which are parallel to the aft-side of the stern-post, causes a space, considerably greater than its transverse section, to be cut in the counter for the rudder to revolve in, which would be impervious to the waves, were it not defended by a coating of tarred canvas, nailed in such a manner to the rudder and counter, as to cover the whole space required. But the ill effects of having so large a space so ill guarded, have proved very dangerous.

It was to remedy this defect that *round-headed* rudders of late years have been adopted in many merchant-ships, particularly

## SHIP-BUILDING.

particularly those in the service of the East India Company.

The round-headed rudder is represented in the sheer-plan of the East India ship, *Plate XII.*, which consists in making the upper part of the rudder above, and some inches below the hole in the counter, cylindrical, and giving that part, at the same time, a cast forward above the upper brace, so that the axis of rotation may by that means be the line passing, as usual, from the heel of the rudder to the upper brace, or that next below the counter, and from thence upwards through the axis of the cylindrical part, or head, in order that the transverse section at the counter may be a circle revolving upon its centre: in which case the space of half an inch is more than sufficient between the rudder and the counter, and consequently the necessity of a rudder-coat entirely done away. But as it was foreseen, that if the rudder was by any accident unshipped, this alteration might endanger the tearing away of the counter, the hole is made from two to four inches larger all round, according to the size of the ship, than the transverse section of the cylindrical part of the rudder, but that space is easily covered over with a wooden rim, about two inches thick, and of sufficient breadth to nail to the counter clear of the hole: this rim is fitted nearly close to the rudder, and is capable of resisting the shock of the sea, but easily carried away with the rudder, leaving the counter, under such circumstances, in as safe a state as it would be, agreeable to the present form of making rudders in the navy.

It is easy to conceive that the braces cannot be carried up so high on the stern-post with a round-headed rudder, as in *Plate I.* But then the head is better steadied, as it has a large bolt driven down through the centre, that traverses in a thick brass plate confined in a strong oaken frame, fixed over the head.

It may also be readily seen, that to bring the axis of rotation through the centre of the rudder-head, it must cast so much forward, as was before observed, which requires a sudden hance between the upper brace and the counter; but to avoid this hance cutting away the main post too much at the head, a false post, sufficiently thick, is tabled or coaked to the aft-side of the main post, as in *Plate XII.*

The body and half-breadth plans may now be completed, as it remains to add the superincumbent part, or top-side.

Transfer the heights of the top timber-line from the sheer-plan, *Plate I.* to the body-plan, and draw an horizontal line, at each height, across each respective body. Now the breadth of the ship at this height determines the tumbling-home of the top-side, which should not be too much, as formerly, as it creates an unnecessary consumption of crooked or compass-timber, or an extravagant waste of large timber, which must be much weakened by being cut across the grain. Again, great advantages would be derived from having little or no tumbling-home to the sides, as it gives more room upon deck, a greater spread to the shrouds, additional security to the masts, makes the ship stiffer, a much better sea-boat, and in every respect safer, stronger, and better. On the contrary, it may be argued, that by the top-side tumbling-home, particularly in ships of war, all the weight of guns, &c. lying above the load-water-line, may thereby be brought nearer to the middle line, when of course the ship will be less strained by the working of her guns also; but others have endeavoured to prove, that by the weights being equal on both sides, they counterpoise each other, and do not strain the ship, whatever distance they may be removed from the middle line. Again, the top-side narrowing or tumbling-home, as it approaches the top of the side, particularly in

ships having two or three gun-decks, the smoke of the lower guns in action less annoys those on the decks above.

In *Plate I.* the top-timber breadth in midship is four feet less than the main breadth, consequently the top-side tumbles home two feet on each side, and may be so continued in the half-breadth plan parallel to the main breadth, from frame 22 abaft to H forward; then from the middle line at K set up 21 feet 11 inches; at M, 21 feet 8 inches; at O, 21 feet 6 inches; at Q, 21 feet; at S, 20 feet 4 inches; at U, 19 feet; and at the beak-head, 17 feet: at 24, in the after body, 20 feet 7 inches; at 26, 20 feet; at 28, 19 feet 6 inches; at 30, 18 feet 9 inches; at 32, 18 feet; at 34, 17 feet 2 inches; at 36, 16 feet; then to end it abaft, square down to the half-breadth plan the intersection of the top timber-line at the side counter-timber in the sheer-plan, and set up, as before, 12 feet. Then a fair curve-line drawn through these spots, represents the top-timber half-breadth.

Transfer the top-timber half-breadths from the half-breadth plan to their corresponding horizontal lines at the top timber-line from the middle line in the body-plan. Now the timbers may be formed above the lower height of breadth in the body-plan, thus; transfer the upper height of breadth-line from the sheer-plan to the body-plan, drawing thereat horizontal lines; then square up the timbers already drawn to intersect the upper height of breadth respectively; open the compasses to 15 feet, the length of the upper-breadth sweeps, and fix one foot on each line last drawn; then from the lines, as squared up, describe an arc of a circle upwards at each timber; then draw at  $\perp$  a curve to the hollow of the top-side, touching the back of the upper-breadth sweep, and the breadth at the top timber-line, thus; the timber at the top-side is formed in midships, to which let a mould be made from the upper height of breadth upwards, continuing the same hollow of top-side some feet above the top timber-line at  $\perp$ , by which mould all the timbers of the top-side, except two or three quite aft and forward, may be drawn, and both bodies completed to the top of the side, by moving the mould at each timber gradually upwards, so as to make a fair line with the upper breadth sweep, touching the breadth at the top timber-line.

The foremost frames, as X, U, and S, towards the top of the side, curve outwards, or the contrary way to those abaft them; because the breadth at the top timber-line projects the main breadth below, by which the anchor is hove up clear of the bow. From their breadth at the top timber-line, square up a perpendicular line to the top of the side, which produces a sudden angle or knuckle at the top timber-line, from whence they are called *knuckle-timbers*.

From the sheer-plan transfer the heights of the top-side to their respective timbers in the body-plan, and draw a curve line through those heights, and the top of the side will be represented in the body-plan. Then, to prove that the heads of the timbers make a fair longitudinal curve, transfer their half-breadths at the height of the top-side in the body-plan to their respective timbers in the half-breadth plan; that is, from frame D forward, and from 10 abaft; if they produce fair curves, the top of the side is correct.

Now the side stern-timber may be drawn in the body-plan, thus: transfer the height of the wing-transom, lower counter, upper counter-knuckles, top timber-line, and top-side, from the side stern-timber in the sheer-plan to the after body-plan, and draw an horizontal line at each height; draw likewise two horizontal lines, equally spaced, between the wing-transom and lower counter-knuckle, and one equally between the upper counter-knuckle and the top timber-line. Transfer the half-breadths of the six after-frames, where they are intersected by the above horizontal lines, to their

corre-

corresponding timbers in the half-breadth plan, and draw curves through the above half-breadths, some distance abaft the after-frame; then square down where the several heights intersect the side stern-timber in the sheer-plan, to the half-breadth plan on their corresponding lines, and from thence transfer the several half-breadths to their corresponding heights on the body-plan; then, by drawing curves through those half-breadths, the side stern-timber will be represented.

The main half-breadth and top-timber half-breadth lines may now be ended abaft in the half-breadth plan: thus, square down from the sheer-plan, where they intersect the side stern-timber, to their corresponding lines in the half-breadth plan; also, where they intersect the middle stern-timber in the sheer-plan, square them down to the middle line in the half-breadth plan; then, with a radius in the said middle line, sweep an arc of a circle to intersect the spots last squared down, which will represent the round-aft of the stern at the main half-breadth and top timber-lines in that direction.

In a similar manner may be drawn the round-up of the stern at the knuckles of the lower and upper counter in the body-plan, by transferring the heights of the lower and upper knuckles, at the middle stern-timber in the sheer-plan, to the middle line in the body-plan; their height at the side being set up before; then, with a radius from the middle line in the body-plan, sweep a segment of a circle to pass through each height, and the round-up of the stern, at each counter, will be represented as in the body-plan, *Plate I.*

#### *Apron, or Inner Stem, &c.*

The *apron* may now be drawn in the sheer-plan, by continuing a line parallel to the aft-side of the stem, at twelve inches, its moulding from the head of the stem, to about seven feet abaft the boxing, by which it will give shift to the scarfs of the stem, as represented by the ticked line in the sheer-plan, *Plate I.*

The cutting-down, or height of the upper side of the floors in the middle fore and aft, is represented by the ticked line at the following heights; *viz.* at  $\Gamma$ , and from frame D to 8, 1 foot 10 inches; at F, 1 foot  $10\frac{3}{4}$  inches; at H, 2 feet  $\frac{1}{2}$  an inch; at K, 2 feet 2 inches; at M, 2 feet  $5\frac{1}{2}$  inches; at O, 2 feet  $11\frac{1}{2}$  inches; at S, 4 feet 6 inches; at U, 6 feet 6 inches; at 10, 1 foot  $10\frac{1}{4}$  inches; at 12, 1 foot 11 inches; at 14, 2 feet; at 16, 2 feet  $1\frac{1}{2}$  inch; at 18, 2 feet 2 inches; at 20, 2 feet 6 inches; at 22, 2 feet 10 inches; at 24, 3 feet 2 inches; at 26, 3 feet  $10\frac{1}{2}$  inches; at 28, 4 feet  $7\frac{1}{2}$  inches; at 30, 4 feet 11 inches; at 32, 7 feet 7 inches; at 34, 10 feet  $1\frac{1}{4}$  inch, above the upper side of the keel; then a curve line drawn through those heights, will shew the cutting-down.

The depth of the *keelson* is also represented by a line eighteen inches above, and parallel to the cutting-down, into which forward is scarfed the *stemson*, which is continued upwards to the under side of the gun-deck hook, and nearly parallel to the apron, it being ten inches moulded at the head. The after-end of the keelson is completed by the sternson-knee, which scarfs into the keelson, and runs up the fore side of the transom to the under side of the carling under the gun-deck beams, as shewn in the sheer-plan, *Plate I.* Sometimes a knee is introduced in the dead-wood, as shewn in the sheer-plan, which lays against the *inner post*, which is fifteen inches moulded at the heel, and one foot at the head at the under side of the gun-deck transom.

#### *Nature and Use of the Timbers, when canted.*

Hitherto we have considered the timbers as having their

planes athwartships, or at right angles, square to the keel, and have consequently called them *square-timbers*. But the *cant-timbers* have their planes inclined forward from the keel in the fore-body, and the contrary way, or aft, in the after-body, or *canted*, as shipwrights term it.

That the reader may clearly understand the nature of the cant-timbers, observe in the half-breadth plan, *Plate I.*, where the joint of cant-timber U intersects the middle line; at which place suppose it hung on a hinge, moving fore and aft; and also imagine the line drawn for the cant-timbers on the half-breadth plan to represent the upper edge of a surface, of a sufficient breadth to form the shape of the said cant-timber from the middle line in the body-plan; supposing the horizontal view of that surface to be represented by that one line. It immediately follows, that the surface must stand perpendicular to the upper edge of the keel, similar to a door swinging on its hinges; and, if we draw the moulding shape of the cant-timber, according to what is laid off in *Plate VII. fig. 3.* upon this surface, from the keel to the top of the side (not moving its position), and then cut it out, we shall have the true position of the cant-timber, as in its place on the ship, which will stand in a perpendicular direction; we may also, supposing it to be hung, swing it or cant it either forward or aft, and it will still maintain its perpendicularity with respect to the keel.

The canting of the timbers is of great utility, as it allits the conversion of the timber, and likewise greatly contributes to the strength of the ship in the fore and after parts. For in the first place, were all the timbers of the bow and buttock to be continued square, as those of the square body, though the scantlings of the square timbers on a square should be equal to the scantlings of the timbers, if canted, yet the bevellings of the bow and buttock-timbers would be so great, that the consumption, in some places, in order to get the timbers clear of sap, would be greater by one half than that in the timbers when canted. And, secondly; by canting the timbers gradually from athwartship line, we thereby bring each timber nearer to a square with the planks of the bottom, which is not only the best position to receive the fastenings of the planks, &c. but the timbers are also better able to bear those fastenings.

We may now proceed to cant the timbers of the fore-body, so that they may stand as square to the curvature of the bow as possible; which will not only greatly lessen the bevelling, but will very much straighten the moulding shape of the timbers; by which means they will be much stronger, not so liable to be grain-cut, and having less compass, the conversion will be greatly allited.

Therefore determine on the cant of the foremost timber, which is y, by setting forward two feet one inch on the run of the main half-breadth line before the perpendicular of X; and its heel nine inches abaft the perpendicular of U, on the stepping-line, which is three inches nearer the middle line than the bearding, or half-thickness of the dead-wood, and draw the ticked line marked c y in the half-breadth plan, *Plate I.* The after cant-timber of the fore-body may be before the foremost square timber O two feet nine inches on the main half-breadth line, and the heel on the stepping-line two feet five inches before O, on the ticked line marked c p, drawn as before; then may the intermediate cant-timbers c q, c r, c s, c t, c w, c x, be drawn, with their joints to intersect their respective perpendiculars as far as U, at the main-breadth-line: then c w and c x equally between c u and c y: draw the ticked lines representing each cant-timber from thence to their heels, which are all equally spaced on the stepping-line, between c p and c y.

The *Hatch-pieces* can now be determined on and drawn in the

## SHIP-BUILDING.

the half-breadth plan, the sides of which may stand parallel with the middle line, or canted square with the bow, which will lessen their heels and bevellings, and assist their conversion, as before observed, by the cant-timbers; their number may be four, besides the *knight-head*, which comes next the stem, unless the apron is sided more than the stem, which cannot be the case when the rabbet is in the middle: as that has now become general, a filling about six inches sided is fayed next the stem, which makes it unnecessary to cast the knight-head above the stem to receive the bowsprit. In the half-breadth plan, *Plate I.* the knight-head is drawn next the stem, therefore set off from the stem one foot four inches, its siding at the top-timber line or head; before cant *y* is introduced a short timber, which shortens the heel of the knight-head and hawse-pieces, not that the heels are expected to be gotten so low down as to lay against it, for if the knight-head runs down low enough to take a bolt through the gun-deck hook, it is reckoned sufficient, the remainder being made good with a chock. From the stem, at the timber or timbers before cant *y*, set up the siding of the heel, which is thirteen inches. In the same manner set off the siding of the hawse-pieces, four in number, from each other, as they lay close together, in wake of the hawse-holes; that is, 18 inches at the head for the first hawse-piece, 17 inches for the head of the second and third, and 18 inches for the fourth; and the siding at the heels to be all alike 13 inches, as in the half-breadth plan, *Plate I.*

The *hawse-holes* may now be drawn, which should be so stationed as to wound the hawse-pieces as little as possible; they may therefore be placed so that the middle or centre of the midship-hole may come in the joint of the first and second hawse-pieces, and that of the outer hole in the joint of the third and fourth hawse-pieces. The holes to be in diameter, *after the pipes are let out*, 17 inches, and in distance from each other on a square 18 inches, to which lines may be drawn in the half-breadth plan to extend from the thickness of the outside to the inside plank, and in a fore and aft direction, so as to cross the middle line of the gun-deck at the main-mast. Sometimes, to avoid wounding the hawse-pieces too much, middle pieces are introduced in wake of the holes sided, about six inches less than the diameter of the holes; then, by cutting three inches on the sides of the hawse-pieces between the holes, those hawse-pieces become consequently more sided, and are wounded proportionally, but little.

The hawse-holes may now be represented in the sheer-plan, thus; set up their height above the gun-deck, which is two feet eight inches, to their under sides, then their diameter above that, which will be clear of the clamps above; then, with a proper stive outwards, we shall find them about six inches above the upper side of the lower cheek, which will leave a sufficient substance of *bolster* under the hole for the wear of the cable. Square up, from the half-breadth plan, where the holes intersect the inside and outside plank at the main half-breadth line, that being very near their height; then by drawing lines to their stive parallel to their depth, they will be represented as the dotted lines in the sheer-plan, *Plate I.*; but to continue them to the outside of the bolster, as the shaded holes in the sheer-plan are, square up from the half-breadth plan, where they intersect the fore part of the cheek.

The cant-timbers in the after-body may now be drawn, and every part depending on them; in order to which we must first determine on the cant of the fashion-piece; therefore, having the round-aft of the wing-transom represented in the half-breadth plan, and likewise an horizontal line at the height of the wing-transom, set off sixteen inches, its

moulded breadth, at the side on the horizontal line, which is the station of the aft-side of the fashion-piece; then, to determine on the cant of it, the shape of the body must be considered, for the more it is canted the straighter will be the timber, and square with the plank of the buttock, consequently stronger and much easier obtained.

Therefore, let the heel of the fashion-piece at the aft-side be nine inches on the stepping-line in the half-breadth plan before perpendicular 34, and drawing a straight line from thence to the fore-side of the wing-transom, as above, the cant of the fashion-piece will be described, and will be found situated in the best manner possible to answer the before-mentioned purposes.

The cant of the fashion-piece being represented, the cant of the timbers before it may be easily determined; let 29 be the foremoil cant-timber in the after-body, which, on the main half-breadth line, may be equally spaced between the after square-timber 28, and the perpendicular 30, and its heel on the stepping-line be one foot nine inches abaft 28, drawing a straight line, as before; the other cant-timbers between 29 and the fashion-piece, which are *c 30, c 31, c 32, c 33, c 34, c 35,* and *c 36,* may be equally spaced on the stepping-line at the heels, likewise on the main half-breadth line, drawing straight lines as before, which will intersect their perpendiculars as far aft as 34 on the main half-breadth line; thus the cant-timbers in the after-body will be represented as in the half-breadth plan, *Plate I.*

The line drawn for the cant of the fashion-piece represents the aft-side of it, as before observed, which lets on to the ends of the transoms; but, in order to assist the conversion with regard to the lower transoms, there may be two more fashion-pieces abaft the former; therefore the foremoil fashion-piece, or that which is already drawn in the half-breadth plan, only takes the ends of the three upper transoms, which are the wing, filling, and deck-transoms; the middle fashion-piece takes the three next, and the after fashion-piece the three lower ones; therefore set off in the half-breadth the siding of the middle and after fashion-pieces, which is 12 inches each; then draw lines parallel to the foremoil fashion-piece at the sidings, and the middle and after fashion-pieces will be represented in the half-breadth plan.

The fashion-pieces and transoms may now be represented in the sheer-plan, as the thwartship appearance of the fashion-pieces limits the length of the transoms as they appear therein: square up from the half-breadth plan, where the fashion-pieces there intersect the stepping, the horizontal or water-lines to their respective water or horizontal lines, and stepping-line, in the sheer-plan; but as the foremoil fashion-piece runs up three or more feet, if to be gotten above the wing-transom, an horizontal line at the head, and three more between that and the load-water-line, should be drawn from the body to the half-breadth plan, in pencil, as they may be rubbed out afterwards, and the intersection of the fashion-pieces squared up as before; then curves drawn through the spots as squared up will represent the thwartship appearance of the fashion-pieces in the sheer-plan, as in *Plate I.*

The height and siding of all the transoms may now be drawn in the sheer-plan, thus; set down 13 inches below the horizontal line representing the upper side of the wing-transom already drawn, and draw a line parallel thereto, which will shew the siding or under side of the wing-transom as far forward as the fashion-piece.

The filling-transom is the next, which nearly fills up the vacancy between the under side of the wing-transom and upper side of the gun-deck plank, and may be represented by drawing two parallel lines under the wing-transom to its siding, which may be ten inches, if it will allow two inches  
between

between its upper side and the lower side of the wing-transom, and four inches from its lower side and the gun-deck plank. The deck-transom must be governed by the gun-deck, letting the under side of the gun-deck plank represent the upper side of it; draw another line at fourteen inches, its siding parallel to the upper side, which will complete the gun-deck transom. The transoms below the gun-deck, which are six in number, are all eleven inches sided, and are represented by drawing horizontal lines from the fore-side of the rabbet of the stern-post; the three upper ones to the middle fashion-piece, and the lower three to the after fashion-piece, keeping each of them about three inches asunder for a free circulation of air. Every means should be taken to preserve them, as they are more difficult to shift than any timbers in the ship.

The stern-post may now be completed, by drawing the fore-side thus; set forward upon the upper side of the keel three feet from the line, representing its aft-side, and likewise twenty inches at the head, which may be three feet above the wing-transom, which will admit of the tiller to be three inches clear of the helm-port transom, and two inches from the under side of the beams above; then a straight line drawn from the heel to the head to the dimensions set off, will represent the fore-side, observing not to draw the fore-side of the post through the transoms.

The *inner post* may be drawn by setting off before the main post sixteen inches, its size at the upper edge of the keel, and thirteen inches at the head, which comes no higher than the under side of the gun-deck transom; then, by drawing a line, as before, for the fore-side of the main post, the inner post will be represented as in the sheer-plan, *Plate I.*

#### *To Design the Perpendicular View of the Stern.*

In designing the perpendicular view of the stern, there will be an opportunity of seeing whether the knuckles of the counters are so disposed, that the lower and second counters are in proportion to the rest of the stern: at the same time, whether the heights of the decks, which, in the present draught, *Plate I.* are sprung abaft sufficiently to give depth to the lights, as well as for other conveniences to make a well-proportioned stern.

Draw an horizontal line at the upper side of the wing-transom at the middle line, in the sheer-plan, body-plan, and likewise for the stern underneath the body-plan, as the basis of the stern, from which all the heights will be set up or transferred. Continue down thereon the middle line of the stern from the body-plan, and drop perpendiculars from the knuckles of the side counter-timber in the body-plan, to the base line in the plan of the stern, and then draw the side counter-timber on each side the middle line, the same as in the body-plan above, and the round-up of the upper and lower counter at the knuckles of each timber. Having the form of the side counter-timbers in the plan of the stern, set within them the scantling of the timber, and draw their insides.

The lower and upper counter-rails being drawn in sheer-plan, try if the under sides at the midship-timber project enough to bury their respective counter-planks, thus; square aft a line from each counter at the knuckle, and on those lines set aft from the knuckle the thickness of the counter-plank, say three inches at the lower counter, and one quarter more, that the moulding may not come to a sharp edge. The lower counter-plank may be increased to four inches, its general thickness. Proceed in the same manner with the upper counter, its birthing being two and half inches thick. This will shew how much the light-part of the rails will be on a level view below the knuckles of the timbers. Then transfer their height to the plan of the stern at the middle,

and keep them parallel to the knuckles to the outside, sufficient for the projection of the quarter-galleries, as in plan of the stern, *Plate I.*

Take the height of the under side of the quarter-deck at the aft part of the middle stern-timber in the sheer-plan, and set it up in the plan of the stern at the middle line; then round the quarter-deck in the stern, agreeable to the upper counter-rail, in the following manner: take the height from the upper counter-rail, in the plan of the stern, to the quarter-deck at the middle line, and set it off in the direction of the side-timber at the inside. This makes the quarter-deck round more than the upper counter-rail, and adds life to the stern; for the upper part of the lights in the stern should be parallel to the transom. As, if they were to round by the same mould as the upper counter-rail, the bars in the fashes next the side would be longer than those in the middle line, and would appear as if the top of the lights rounded less than the upper counter-rail. Draw in the upper part of the lights about an inch and half below the under side of the quarter-deck transom, and their lower part about six inches above, and parallel to the upper counter-rail, which will allow sufficient depth for the water-table. Set off within-side the stern-timbers, in the plan of the stern, the thickness of the clamps, and the projection of the cornice in the cabin, and let that be the side of the lights.

Then determine on the breadth of the munions, allowing sufficient for the weights and pulley-pieces, and divide the fashes, six in number, equally.

Now, as well-proportioned lights are great ornaments in sterns, having the breadth of the lower part of the lights in the clear, let their depth be at least one-third more than the said breadth; set off upon the rake of the stern-timbers, in the sheer-plan, and transfer that to the plan of the stern, which makes a good proportioned light. Set off likewise the mock-light in the aft part of the quarter-gallery the same size as the rest.

Then to rake the fashes regularly from the middle to the sides, continue upwards the middle line and the outside of the side stern-timbers in the plan of the stern, till they intersect at the said middle line; then from their spacings at the lower part, the sides of the lights may be drawn to their heads, or upper part, with a straight batten fixed at the intersection of the middle line. In the same manner may all the intermediate stern-timbers be drawn to their siding in the middle of each munion from the wing-transom to the under side of the quarter-deck, likewise the shorter ones that make the side of the counter-ports, and those under the middle of the lights to the upper counter-rail. At about half the breadth of the munions from the mock-light, place the inside of the quarter-piece; then set off at the heel sixteen inches, its moulded breadth, and continue upwards the outside of the quarter-piece, as before, for the lights. In the middle of the quarter-piece, or nearly so, place the outside of the gallery, which determines the projection of the gallery from the side. Draw in the plan of the stern the foot-space rail, its under side to be about an inch and a half below the aft part of the quarter-deck, and parallel thereto to the outside of the quarter-piece; likewise draw the breast-rail, transferring its height from the sheer-plan at the after-part, and set it up at the middle line as in the plan of the stern, and rounding it, as described for the quarter-deck, to the inside of the quarter-piece. Then let the round-house deck be drawn in the plan of the stern as directed for the quarter-deck, which will determine the lower part of the taffrail, as the necking-moulding should be kept an inch and a quarter below the round-house transom. Then may the boundary, or upper part of the taffrail and quarter-pieces, be finished as in the plan of the stern.

**tern.** In the starboard quarter-piece is designed the aft part of the gallery, which is at the middle of the quarter-piece in the sheer-plan; therefore it will be proper to draw the form of the middle of the quarter-piece, and the fore-side of the taffrail, upon the sheer-plan. Thus, take the heights from the level line at the upper side of the wing-tranfom in the plan of the stern, to the lower part of the quarter-piece, or upper side of the upper counter-rail, and likewise in as many places as may be found necessary, to get the exact form, and fet them up in the sheer-plan, drawing level lines. Square up the spots on the quarter-piece and taffrail to the round-aft of the stern on a level; then take what the round gives at each spot squared up, and fet it off from the midship stern-timber on their corresponding level lines in the sheer-plan. This produces the ticked line that was drawn in pencil in the sheer-plan, shewing the middle of the quarter-piece and fore-side of the taffrail. Take the siding of the taffrail, and draw the aft-side of the taffrail and quarter-piece parallel to the middle line of the quarter-piece, and fore-side of the taffrail, and draw likewise the fore-side of the quarter-piece parallel to the middle. By the same method, prove the thwartship view in the sheer-plan of the lower side of the taffrail, and inside of the quarter-piece.

Take the height in the plan of the stern of the upper counter-rail at the outer part, and fet it up in the sheer-plan, drawing a level line. But to find how much the after-end of the rail will be before the knuckle of the upper counter at the side-timber, the round-aft of the upper counter-rail must be laid down on a level, as in the half-breadth plan; transfer the outer end of the said rail square from the middle line in the plan of the stern, on to the round-aft square from the middle line in the half-breadth plan; then square it up to the sheer-plan, on the level line last drawn. Design the lower gallery rim, with the lights and munions, as in the half-breadth plan, which is a continuation of the upper counter-rail, and this will determine the length of the gallery in the sheer-plan. Take the height in the plan of the stern to the foot-space rail, at the outside of the quarter-piece, and transfer it to the aft-side of the quarter-piece in the sheer-plan. Take likewise the upper and lower part of the lights in the plan of the stern, at the birthing of the outside of the gallery, and fet them up in the sheer-plan, at the ticked line, for the middle of the quarter-piece. Design the lower finishing as in the plan of the stern, and transfer the height and round-forward of the lower counter-rail, as before described, at its outer end, and then draw all the rails and lights, as fet up in the sheer-plan, from thence forward, agreeable to the sheer of the ship, to their boundary, or fore part of the quarter-gallery.

Lastly, the upper finishing being designed in the sheer-plan, transfer their heights, and complete the quarter-gallery, as drawn in the starboard quarter-piece in the plan of the stern, *Plate I.*: the aft-side of the rudder, counter-ports, and helm-port tranfom, may also be drawn.

#### *To Design the Plan of the Head.*

Continue forward the middle line of the half-breadth plan. Upon it square down the fore-side and aft-side of the figure from the sheer-plan, and upon those lines fet off the half-siding of the figure.

Then draw the main rail to its half-breadth appearance, thus: fet off the siding of the after-end of the main rail from the outside of the plank at the top-timber half-breadth, to the fore-side of the beak-head in the half-breadth plan; and also the siding of the fore-end from the outside of the figure, the fore-end being square down from the fore-part of

the hair-bracket in the sheer-plan; observing, however, to add to the siding the thickness of the lining: then, by drawing straight lines to those spots, the half-breadth plan of the main rail will be represented as in *Plate I.*

Square down from the sheer-plan the head-timbers, where they intersect the under side of the main-rail, to the middle line of the half-breadth plan: likewise square down the fore and after-sides of the knight-head, and draw the half-breadth line at the upper side of the beak-head-flat, and the thickness of the outside plank.

Square up from the middle line in the half-breadth plan the head-beam, so as to let aft about two inches upon the stem; and square up likewise the cross-piece close to the aft-side of the foremost head-timber, to which and the head-beam the main rail is secured by knees on the aft-side.

Draw the moulding size of the upper cheek as you see the ticked line in the half-breadth plan, then the half diameter of the bowsprit parallel to the middle line; and also the fore and aft carling as much without the bowsprit as the gammoning may lead down clear of the bowsprit, and outside of the upper cheek.

The seats of ease, no less than two double ones, should be placed the most conveniently, as shewn in the plan. The remaining space of the flat of the head may be composed of ledges: and, lastly, may be drawn the boomkins, which spread the fore-tack, thus; square down from the centre of the fore-mast from the sheer-plan to the middle line of the half-breadth plan, and from that intersection draw a line forward, to form an angle of thirty-six degrees with the said middle line; and upon it fet off half the length of the fore-yard; then draw in the boomkin parallel to the line representing the fore-yard braced up sharp, and it will come nearly over the middle head-timber on the main rail, its heel resting against the knight-head; the length may be ascertained by a line drawn from the fore yard-arm at the outer end.

The round-houses, or seats of ease for the officers, are clearer shewn in the plans of the upper deck and forecastle; which plans and draught of the inboard works will be designed hereafter, the sheer-draught plate being completed.

#### *To Design the Disposition of the Frame. Plate II.*

The utility of a plan of this description requires but little explanation; as it is evident, upon inspection, that it exhibits the disposition and shift of every timber, and consequently affords the means of disposing of every piece to the greatest advantage, both with respect to the strength of the ship, and to the conversion of the timber; and, moreover, of preparing every piece for its proper situation, before the ship comes on the stocks, with the greatest facility.

The frame timbers are formed into bends, as before observed, by the union of first futtocks, second or middle futtocks, third and fourth futtocks, with top-timbers, which are severally scarfed together and bolted. Sometimes the frames are layed close together, or separated, for air; those that are separated have dry pieces of oak layed between them in wake of the bolts; these should all be split out before the planking is brought on, that a free passage may be given for the circulation of air.

By the disposition of the frames in their several stations, they stand respectively one on each side of every gun-deck port, by which the sides of every middle and upper deck port are likewise provided for. Thus, one fourth futtock and one long top-timber will form the side of every gun-deck port in two-decked ships, and the side of every upper deck port in three-decked ships. A long top-timber and a

## SHIP-BUILDING.

fourth futtock will, in like manner, make the sides of the middle deck ports in three-decked ships, and the sides of upper deck ports in those of two decks.

With respect to the frame-timbers, it is, in the first instance, of the greatest consequence to the strength of a ship, that they should be cut as little as possible by the ports on each deck, scuttles, scuppers, &c.; and, secondly, that all the timbers designed to make the sides of ports, are, or should be, continued, if possible, without scarfing, up to the top of the side. Those timbers, however, in the sudden turn of the body, having so much compass in their length, and others which run up to receive the rough-tree rail having too great a length to be otherwise obtained, must be admitted to scarf, as shewn in the disposition, *Plate II.*

Those timbers that run up to make the sides of quarter-deck ports, forecattle ports, or to the rough-tree rail, should, if possible, be made of timbers standing up on the upper deck fills, over the upper deck ports. The side along the waist, between the ports, may be filled in with fir timber, laid fore and aft, and dove-tailed into the frames.

All timbers in the range of the fore and main channels should run up to the top of the side; and the filling-timbers between each frame are all to be equally spaced between the frames; and all the openings between the range of the chain and preventer-bolts are to be filled in solidly with dry oak-fillings, as are also those over every gun-deck and middle deck port, that there may be solid boring in wake of the port-rope-pipes, and muzzle-lashing eye-bolts; also behind iron knees and standards. But as fillings of this kind interrupt the free passage of the air, let a hole, one inch and upwards, be bored throughout their length. All fillings should be charred, or burnt.

All ships should be as light as possible in their upper works, consistently with the services for which they are intended; and, as the frame should not be incumbered with more short timbers than are absolutely necessary, two timbers over each point are sufficient. The frame will be adequately full, and every purpose answered, when timbers are provided to form the gallery doors, and to fill in the quarters from the after-frame to the side stern-timbers; and forward, from the foremast frame to the hawf-pieces.

Having considered the several subjects above-mentioned, transfer from the sheer-draught, *Plate I.*, the keel, likewise the stem and stern-post, with the transoms, and stepping-line for the heels of the cant-timbers, the under side of the decks at the side, also the ports, the plank-sheers, rough-tree rails, and beak-head; then the side stern-timber.

Square up from the half-breadth plan, *Plate I.*, the joints and sidings of the cant-timbers, where they intersect the water-lines, main and top-breadths, and plank-sheer, to their respective lines in the sheer-plan, as *Plate I.* at *c*, *u*, in the fore-body, and at *c*, *32* in the after-body. Thus may their thwartship appearance be transferred to the disposition, *Plate II.* In the same manner may be squared up the thwartship appearance of the knight-head and hawf-pieces, which may likewise be transferred as the rest, and also the hawf-holes.

The height of the heads of all the timbers may now be taken above the base line in the body-plan, *Plate I.*, and transferred to their respective timbers above the upper edge of the keel, in *Plate II.* Curves being drawn through those heights, will shew the head of each timber on a perpendicular view in the disposition.

Now square up in the disposition the sidings of all the

timbers between the cant-bodies; and as the upper deck ports are less fore and aft than those of the gun-deck, the upper part of the frame-timbers must be opened so much from the joint. The frame-timbers may now be marked with their respective names, likewise the single timber dead-flat, where the body turns to shift the floors, as they are always under-bevelled.

The fore-side, or moulding of the side stern-timbers, may be drawn, and the gallery doors from the sheer-plan, *Plate I.* Then the fills, and all the timbers necessary to frame the quarters abaft frame 36.

The ports being drawn, their fills may all be represented; making the upper fills in wake of the chain-bolts much deeper. Then the blocks through the side should be drawn, that the long timbers may not be provided, and afterwards cut asunder by those blocks; namely, the main tack-block between D and B, the fore sheet-block between 4 and 6, and the main sheet-block between 24 and 26.

The fourth futtocks being the longest timbers in the ship, and, from their shape, very difficult to be gotten of the whole length, especially for ships which have much tumble-home, or even long enough to run up so as to make the side of the upper deck ports, particularly forward and aft, the sides of such ports should have their fourth futtocks scarfed together with a hook and butt, as at fourth futtock 26 in the disposition, *Plate II.*, giving shift to the port and each other: or, if preferred, the scarf sideways, as represented at fourth futtock O.

The third futtocks that come under the gun-deck ports, are to be continued upwards to the under side of the fill, as at D. But when the third futtocks, owing to their great compass, cannot be gotten so long, they may be scarfed, as at 4, observing always to get them longer than the regular shift.

The design of *Plate II.* is to have at one view every timber on one side the ship, that the utmost care may be taken to reduce every timber to the shortest length admissible; as, in a disposition of this kind there is every opportunity of so doing; and likewise of pointing out and converting to the best advantage the most scarce and valuable timber.

*The Design of Expanding the Bottom and Top-side.* *Plate III.*

The design of expanding the bottom and top-side, is to have the lengths and breadths of all the planks at one view, that the planking may be shifted agreeable to the lengths to be obtained, so as to run no hazard of beginning with a shift of planking that could not afterwards be continued. For the planking of a ship is a branch so very material, that, unless it be judiciously performed, it will unavoidably be very injurious to, or subversive of, those good qualities that might be expected from the superior construction of the ship. The planking ought, therefore, to be particularly well performed: as, in the proper shifting, fastening, and caulking, the goodness of every part of the materials for that purpose should, consequently, be very carefully inspected.

The length of plank is a very great object to be considered; and, in the shifting, it is principally to be observed. For English plank it is allowed, and hath generally been found to answer, that if three whole planks be wrought between every two butts on the same timber, and all the butts to have a six-foot shift, or be in distance from each other six feet, the planks will only be twenty-four feet long: this shift is generally followed, excepting for the wales, &c. for ships of every class in the royal navy. But as English oak-plank, having sufficient breadth at the tops in that length, has become exceedingly scarce, merchant-ships have the planks

## SHIP-BUILDING.

planks shifted of various lengths, according to their thicknesses; as two and a half and three-inch plank to have a six-foot shift, and two planks between; and four-inch plank and upwards, to have a five-foot shift, and three planks between every two butts on the same timber. It is possible, however, to have a very bad shift, and yet have three strakes between every two butts on the same timber: that is, when the butts rise one above another in a regular manner, like steps; for, as the upper butts, or those in the top-side, are the most likely to give way, all below would be inclined to follow; as, if the ship begins to break her sheer amidships, it is most probable that the butts afore and abaft would yield proportionably; therefore, let one of the butts between have a double shift, or extend twelve feet; then will the stepping of the butts before mentioned be prevented, and the planks be twenty-four feet long.

The *wales* must be wrought of such length, and the butts shifted, so as to give the strongest shift to the ports and each other. To do this, some of the planks in midships should have a three-port shift; that is, should over-launch three ports; being careful, in large ships, to make one butt answer for the pump-dale scupper. To assist the conversion, the planks may be wrought top and butt. When the wales consist of four strakes, they have a fair seam in the middle; but if wrought in three strakes, let the two lower strakes be worked top and butt, and the upper strake of a parallel breadth.

The *thick-stuff*, or diminishing strakes, from the lower edge of the wale to the thickness of the bottom plank, being of English oak, is wrought top and butt, and should be shifted from the butts of the wales to the regular lengths of the bottom plank as soon as possible.

The *plank of the bottom* is English oak-plank; as low as the light water-mark, and below that, may be East country plank of the best quality. The English plank is worked top and butt, to twenty-four-foot lengths at least. Now, to break the shift, so as to work East country plank to advantage, requires care; for, as just observed, the general shift of English plank is twenty-four feet, whereas East country plank is from thirty to fifty feet; consequently, the best way is to work a double shift at first, or one of forty-eight feet in length. It rarely happens that the shift is broken from English plank to East country plank, without introducing two planks between two butts on the same timber in some places; and, it may be admitted, owing to the superior length. Be careful, in shifting the East country plank, to keep the shift as nearly equal as possible, not being confined to butt on one timber, but to make an advantage of drawing the butts having no less than a six-foot shift.

East country plank is wrought of a parallel breadth from ten to eleven inches, excepting forward and aft; for the fore and after-hoods that come into the rabbet should be English oak-plank. Four or six strakes nearest the keel may be of elm or beech, observing to shift the butts clear of the scarfs of the keel; and, likewise, that no butt is placed under the pumps, and to work them very broad at the post. The edges and butts of the six or eight strakes next the keel in East India ships, are rabbetted close; and fine flannel, dipt in tar, is put between, and thick kersey, also dipt in tar, is spread between those planks and the timbers.

In planking the fore part of the bottom, the breadth of the strakes must be considered, and also the shape of the bow, that every strake of plank may be brought into the rabbet; and every plank should be kept from slying as much as possible. But, in full-bowed ships, it would be impossible to bring every strake to the stem without too

much sly. It is, therefore, customary to work in the bow of such ships a drop-strake next under the wale, or more, if necessary, and a steeler at about four strakes under it; by which means all the strakes that come in the rabbet will be of sufficient breadth. In order to take out the sly, bring the steeler well forward. In most ships, a drop-strake abaft, close up under the wale, assists the planks very much; and to produce a fair edge, be careful not to work too broad on the fashion-piece.

The *plank of the top-side* is generally wrought in parallel breadths, therefore it had better not be more than nine inches broad. The top-side, being cut by the ports, drifts, &c. requires the greatest strength to be given to it in shifting the plank; as no butt should be placed immediately over or under a port, unless there are two planks between. The planks in wake of the main-mast should have a three-port shift: the others, afore and abaft, may have a two-port shift. As it is stronger to butt between the ports, it may be allowed sufficient to have a shift of 5 feet 6 inches, where a plank comes between; or five feet, where two come between. But there should not be less than a six-foot shift where no plank comes between. The channel and sheer-wales, in large ships, should work down to the stops of the ports in midships; and, where the sheer lifts forward and aft, should work down to as many ports as may leave sufficient stop, and afford wood to receive the port-hooks, letting the wood so worked down be continued six inches each way beyond the stops of the ports; thence to hance one foot to the regular breadth: but, by all means, let planks run through, if they hold but five inches after the stops are cut, so as that the port-hooks will clear the seam; for planks, however broad, working down to the ports, make that part no stronger than any other.

Forward in wake of the hawse-holes, the planks should be so wrought as to have the seam to cut the plank as little as possible by the holes; and care must be taken that no seams come behind the cheeks.

The sheer-strakes, as they are the greatest strengtheners of the upper part of the top-side, should have their butts disposed with the utmost care, in order to produce the greatest strength between the drifts, and give the strongest shift to each other. They are wrought of parallel breadths, with hook and butt scarfs about four feet long between the drifts. The butts afore and abaft may be square, especially behind the channels, which should be of English oak. The others, owing to their great lengths, must be of East country plank.

Observe; if the channel or sheer-wales are in three strakes, two of them may be wrought top and butt, to assist the conversion.

In *planking the inside*, attention must be paid that the butts of the clamps, spirkittings, and strings in the waist, should give shift to the butts outside.

Clamps, when wrought of a single strake, should have hook and butt scarfs about four feet long.

Gun-deck clamps and spirkitting should have a three-port shift in midships, as should likewise those of the middle and upper deck. Clamps and spirkittings, when wrought in two strakes, may work top and butt, and one butt of the latter is to come in wake of the pump-dale scupper.

The clamps of the lower deck cannot be wrought towards the after part of the ship, agreeably to the hang of the deck, so as to admit of the after-beam's coming home to the timbers, as it would wound them too much, or produce too great a sly; therefore the clamps may lift aft to produce an easy edge, and some of the after-beams, of course, must face on the clamps.

## SHIP-BUILDING.

However desirable a three-port shift may be with regard to strength, planks of that length are hard to be gotten; therefore, to add security to a two-port shift, let the plank below or above the butt be douelled into each timber next the butt, and likewise edgeways, keeping the douls clear of each other.

To design on a plan the body of the ship, shewing the lengths and breadths of all the planks as near as is required for practice, will be found by experience to be necessary; for when the ship is planking, without a plan of this sort to assist, it is requisite to girt the body in several places, to know the number of strakes the bottom will require, in order to work the planks of each quality of an equal breadth, and likewise to know the diminishing of the breadths of the planks forward and aft. To do this satisfactorily, without a plan, is attended with much inconvenience and trouble. It also affords an opportunity of not only shifting the work before it be immediately wanted; but by having the whole shift of the bottom and top-side before you at one view, you have a better opportunity of seeing whether the butts are sufficiently clear of each other, which is better than seeing them on the ship's side. And when the ship is planking, if there should be any lengths which may prove difficult, you may, by referring to the plan, see if the butt can conveniently be altered, without prejudicing the shift that is not wrought; some part of which it is likely may be altered to conform thereto.

The bottom may be expanded by the horizontal or water-lines, also by the ribband-lines; therefore, from the sheer-plan, *Plate I.*, may be taken the station of all the timbers, and the lower edge of the rabbet of the keel, from the aft-side of the rabbet of the stern-post, to as far forward as the rabbet of the keel continues straight, that is to timber M; likewise the scarfs of the keel; all of which are to be set off on the plan of expansion, as in *Plate III.* Then to expand the square body, transfer the heights of the upper and lower edge of the main-wale, channel-wale, sheer-strakes, upper and lower sides of all the ports, the height of the decks at the side, and under side of the plank-sheer, from the sheer-plan, *Plate I.*, to the body-plan. Transfer from the body-plan the half-breadth of the timbers at the upper and lower edge of the main-wale, channel-wale, sheer-strake, and under side of plank-sheer, to the half-breadth plan, and draw in the lines to their half breadth; which being done, apply to those lines, and also to the horizontal or water-lines, narrow slips of paper, confining them thereto by needles or small pins, from dead-flat forward to square timber O, and from thence abaft to 28; marking upon each slip of paper the station of every timber, and its respective water-line, &c. as girted.

In the same manner, girt the timber dead-flat in the body-plan, *Plate I.*, from the inside of the rabbet of the keel to the under side of the plan-sheer or gun-wale; then mark upon it the heads of the timbers, water-lines, upper and lower edges of the wales, and ports; likewise the decks at the side and under side of the plank-sheer. Then square up the station of dead-flat, as shewn on *Plate III.*; and upon that line set up the middle of the rabbet, to which spot fix, with a needle, the spot corresponding thereto on the slip of paper that girted dead-flat; then upon the line mark off from the said slip the water-lines, heads of the timbers, upper and lower edges of the wales, ports, &c. In the same manner proceed to girt every square timber in the body-plan, *Plate I.*, marking thereon the name of its respective timber. Then fix the spot marked for the middle of the rabbet of each girt, to the middle of the rabbet of its respective timber in *Plate III.*

Now fix the girt of each water-line, &c. as taken from the half-breadth plan, to its corresponding height, as marked on dead-flat, *Plate III.*; then stretch each girt, observing it does not pucker, in such a manner that the stations of the timbers, as marked on the girts of the water-lines, &c. and their corresponding heights, as marked on the girt of each timber, may intersect each other; then with needles confine them in that situation, and make dots at every intersection, which will represent the expanded heights and lengths of all the water-lines, main-wales, &c. in the square bodies. Fair curves may then be drawn through all these dots, which will shew the square bodies expanded from 28 aft to O forward.

Then, to expand the cant-bodies afore and abaft, proceed to draw in pencil the joints of the cant-timbers in the body-plan, *Plate I.*; thus, lay a slip of paper in the direction of each cant-timber in the half-breadth plan, and mark on it their intersection at each water-line, main-wale, channel-wale, ports, sheer-strake, and plank-sheer; also the middle of the rabbet of the keel and stem, and middle line. Then transfer each timber so marked to the body-plan, *Plate I.*; and mark on each corresponding line their half-breadths from the middle line; then curves drawn through those spots will represent the joint of each cant-timber from the keel to the top of the side. In the same manner draw the sides of the short timber before cant y.

The thwartship view of the joints of all the cant-timbers being represented in the sheer-plan, *Plate I.*, square up from the half-breadth plan the fore-side of cant y and the timber before it, and likewise the sides of the hawse-pieces, where they intersect the water-lines, main-wale, &c. to their corresponding lines in the sheer-plan. Then drawing lines in pencil through the spots so squared up, the thwartship view of the hawse-pieces, and the cant-timber before y, will be also represented in the sheer-plan.

Now draw in pencil the fore and aft view of the hawse-pieces in the body-plan, *Plate I.*, by setting off their siding at the heads and heels from the side of the stem, and draw straight lines to intersect the fore-side of cant y and the timber before it; then transfer the height of the heels from the sheer-plan, where they cut off against the foremoft timbers, to the same timbers in the body-plan, as in *Plate VIII. Laying-off B, figs. 1 and 2.*

Transfer the heights of the main-wale, &c. where they intersect the joint of the cant-timbers in the sheer-plan, *Plate I.*, to their corresponding timbers in the body-plan. Then with slips of paper girt the cant-timbers, as before, for the square ones, marking all the heights set off, and the heels where they cut the stem forward and those abaft on the keel.

Likewise girt each water-line, main-wale, &c. from square timber O, in the half-breadth plan, round to the stem, marking thereon the joints of all the cant-timbers, the sides of the hawse-pieces, and stem; then girt the stem in the sheer-plan from M, marking O, the heels of all the cant-timbers, and the heights of the water-lines, wales, &c.

Then place the girt of the stem on *Plate III.*, confining it at M; and likewise fix all the girts of the cant-timbers in the fore-body, confining their heels respectively to their stations on the stem; also the girts of each water-line, wales, &c. confining them respectively at square timber O; then move the whole till they all agree, that is, the ends of the water-lines, &c. are to agree with their respective heights on the girt of the stem, confining them with pins till the whole of the fore cant-body agree, and as much as possible let them lie smooth, without puckering. Then may be marked on the plan the proper edges of the slips of paper, which

## SHIP-BUILDING.

which will represent the moulding edges of the cant-timbers, the water-lines, wales, &c. Likewise mark the heads of the timbers, as taken from the body-plan, as the slips now lie, which heads may be drawn when the slips of paper are taken up.

The findings of all the timbers may then be drawn from their moulding edges, and the openings shown where required for air, or to make the sides of ports, observing to taper the heels of the cant-timbers on the stepping-line.

The operation of expanding the after cant-body is so similar to the above as not to need repetition; therefore, supposing the after cant-body to be expanded as far aft as the fashion-pieces and stern-timber, there only remains to be explained the expanding of the transoms.

The buttock-lines being drawn in the several plans of *Plate I.*, proceed to draw in pencil the moulding edges of the transoms in the half-breadth plan, thus: lay a slip of paper in the direction of the upper edge of each transom in the sheer-plan, and mark thereon where they cut each buttock-line fore-side of the rabbet of the stern-post, and the after perpendicular.

Square down the after perpendicular to the half-breadth plan, and therefrom set off each transom on its corresponding buttock-line, and the rabbet on the half-thickness of the post. Then draw curves through those spots, till they intersect the aft-side of the fashion-pieces, and the moulding edges of the transoms will be represented in the half-breadth plan.

Now draw in pencil the transoms and buttock-lines, where they cross the aft-sides of the fashion-pieces in the body-plan, by transferring their heights from the sheer-plan, where they intersect the thwartship view of the fashion-pieces on the aft-side.

Provide narrow slips of paper, as before, and extend one round the aft-side of each fashion-piece in the body-plan, *Plate I.*; and mark thereon where the upper sides of the transoms and buttock-lines cross them. Then place other slips round the moulding edges of the transoms, below the wing-transom in the half-breadth plan, marking the aft-sides of the fashion-pieces against which the transoms cut off, and the several buttock-lines, as also the side of the stern-post, or inside of the rabbet, which is the extreme length of the planks when worked. Then extend other slips of paper round the several buttock-lines in the sheer-plan, *Plate I.* and mark on them the aft-sides of the fashion-pieces, and the moulding or upper edges of all the transoms below the wing, and likewise the margin-line of the wing-transom, which is the end of the buttock-lines and planks also. Then place the slips of paper as on *Plate III.*, those for the heights of the transoms and buttock-lines to the aft-sides of the fashion-pieces, respectively marking their heights, to which fix those for the buttock-lines and moulding edges of the transoms to correspond; then move both the latter, till their corresponding spots agree together, and so confine them with pins: then mark the proper edges of the slips of paper, which will give the expanded form of the moulding edges of the transoms, and likewise the buttock-lines as they properly intersect the transoms. The farthest spots on the papers of the transoms give the boundary of the stern-frame at the inside of the rabbet, and the farthest spots on the papers of the buttock-lines and the margin, of the wing-transom.

In the same manner may be taken off the lower edges of all the transoms, and draw the upper part of the wing-transom, which makes the stern-frame complete.

Take a slip of paper, and place it up the rabbet of the stern-post, in the sheer-plan, *Plate I.*, and mark on the paper the lower edge of the rabbet of the keel, the three

lower water-lines, and the lower edge of the lower transom; then place the slip of paper as in *Plate III.*, keeping the spot for the lower edge of the rabbet well with its corresponding spot on the keel; and move the slip of paper, till the marks for the water-lines and lower edge of the transom agree with their extremities; then, by marking the edge, the post will be described, and the boundary of the planks below the transom.

The operation may be performed by the ribband-lines, as well as by the water-lines, as before observed; but in that case, the cant-timbers must have been drawn in the body-plan, *Plate I.*, on the square as well as on the cant, to level through their proper heights, which was omitted, to prevent confusion: nevertheless the lower ribband is represented in *Plate III.*

The whole side being now expanded, the planks of the bottom and wales may all be represented, agreeable to the foregoing directions. Likewise, on the top-side we have an opportunity of seeing the distance of every seam from the port-fills, whereby you may judge whether it is better to cut down upon the strakes for the ports, or to work the strakes somewhat broader, to correspond with the stops of the ports. This should be carefully examined, otherwise you will be under the necessity of making a bad shift in the top-side; or be forced to cut so low down upon the lower strake, that the bolts, which are driven through the lower fills, will be of little use; and also to cut up so much for the upper part of the ports, that there will not be left sufficient wood for the port-hooks to bear the weight of the ports; inconveniences which ought to be well considered, before it be too late to alter them.

The strength of the ship, with respect to keeping her from breaking her sheer, chiefly depends on the shift of the planks from the water to the gun-wale, of which the greatest care should be taken to make the best possible, agreeable to the usual lengths of the planks; and likewise that the inside plank, especially the strake above and below the ports, should be shifted as clear as possible of the outside strakes.

The longer the planks in the top-side are wrought, the stronger must be the work; but then it would be imprudent to work longer than the usual length of the planks, because when the ship wanted repair, you would be forced to cut plank on purpose, and thereby work green plank instead of seasoned. The breadth of the planks should be consulted, before you determine on the number of strakes in the top-side, as before observed; for if the planks are rather narrow, the top-side will look the neater, and be equally as strong, if not bored too much.

*To design the Profile, or inboard Works of the 74-Gun Ship, with Observations on the inboard Works of Ships in general.*  
*Plate IV.*

Sometimes the inboard works are drawn in the sheer-plan of *Plate I.*; but when so drawn, they appear so confused, that the best and readiest method is to appropriate a draught for that purpose, as *Plate IV.*, in which every particular will be more clear and conspicuous.

To construct this draught, it will be necessary to take from the sheer-plan of *Plate I.* the scale, keel and scarfs, stem, stern-post, rudder, counter-timbers, fashion-pieces, transoms, cutting-down line, keelson, apron, stemson, all the decks, and centres of the masts; also the drifts, plank-sheer all fore and aft, the joints of the frame-timbers, and the ports.

The stations of the beams are next to be considered, and should be so disposed as to come one under, and one between, each port, or as nearly so as possible, to answer the  
other

## SHIP-BUILDING.

other works of the ship, as the hatchways, ladder-ways, mast-rooms, &c.; but where a beam cannot possibly be placed under a port, or too wide apart, then a beam-arm, or half-beam, should be introduced to make good the deficiency.

To dispose of the beams, as in the profile, *Plate IV.*, draw a fine pencil line under the deck-line at the side, and parallel thereto, to the moulding of the beams, which is for the gun-deck, 16 inches; upper-deck, 12 inches; quarter-deck and fore-castle,  $8\frac{1}{2}$  inches; and round-house, 6 inches. Then place the first beam of the gun-deck under the middle of the first port, or nearly so; the second between that and the third, which takes the heels of the bowsprit-step; the aft-side of the latter to be 3 feet 10 inches before the centre of the fore-mast; the fore-side of the fourth to be 2 feet 6 inches abaft it; the aft-side of the fifth to be 10 feet 9 inches abaft the centre of the fore-mast, against which are the fore riding-bitts; the aft-side of the seventh to be 21 feet 10 inches abaft the said centre, which takes the after riding-bitts; the sixth comes equally between; the aft-side of the tenth beam plumbs the after-part of the fore-castle, or nearly so, and makes the fore-side of the fore-hatchway, which is 4 feet 10 inches fore and aft, and is made by the eleventh beam; the ladder-way between the ninth and tenth beam is 3 feet 2 inches in the clear; the aft-side of the twelfth beam is 5 feet 8 inches abaft the fore-hatchway; and the fore-side of the thirteenth 11 feet; between these two beams are let down the fore-jeer capstan-step. The fore-side of the seventeenth beam is 5 feet 8 inches before the centre of the main-mast, and makes the aft-side of the main-hatchway, which is 8 feet fore and aft, and is made by the sixteenth beam; the eighteenth beam is 9 feet 9 inches in the clear abaft the seventeenth; and the nineteenth 4 feet 10 inches in the clear, which makes the after-hatch; the aft-side of the twenty-first beam is 12 feet abaft the after-hatch; and the twenty-second 5 feet 6 inches in the clear abaft it, which takes the step of the main-jeer-capstan; from the twenty-third to the thirtieth are about 4 feet in the clear afunder. Between the twenty-third and twenty-fifth is the ladder-way to the cock-pit, and hatch to spirit-room; and the twenty-sixth beam should be placed exactly under the centre of the mizen-mast, all the beams having any thing attached to them being particularized. The intermediate ones may be equally spaced between them; and their sidings, which are 16 inches, may now be set off, and each beam be drawn. But as beams are seldom made of less than two pieces, the lips, which are four inches, had better be added to the siding.

On the *upper deck* the first beam is placed under the beak-head, to receive the tenons of the beak-head stantions; the second beam must be so fixed, as not to be too much wounded by the bowsprit; the third and fourth about 2 feet 6 inches in the clear on each side the centre of the fore-mast; the others, particularly those that have pillars under them, should be stationed over those of the gun-deck; from the fifth beam to the tenth is let up in the middle 2 inches of the fore-hearth carling, which is 12 inches square; between the tenth and the eleventh beam is the fore-hatch over the gun-deck, abaft which is a ladder-way, and next abaft it the capstan; the seventeenth beam takes the top-fail-sheet-bitts on the aft-side; and the next beam before makes the fore-side of the main-hatchway, before which is a ladder-way about 4 feet 6 inches in the clear. The eighteenth beam on the fore-side takes the main-jeer-bitts, and the next abaft makes the after-hatchway; between the twenty-first and twenty-second is the capstan-room, which should be at least 5 feet 8 inches in the clear, to admit the capstan. From the twenty-second to the twenty-fifth are gratings, and a

ladder-way to the gun-room, &c. The transom abaft scores in to the stem-timbers.

The *quarter-deck beams* having no framing of carlings and ledges as the others below, require nearly twice the number in the same length, and a greater round-up, otherwise they would be apt to bend with their own weight.

The length of the quarter-deck is determined by having the aft-side of the foremost beam about four feet before the centre of the main-mast, and in general receives the tenon at the heads of the main-top-fail-sheet-bitts; the second beam is about 4 feet 6 inches abaft the centre of the main-mast, and receives the tenon at the heads of the main-jeer-bitts; of late these bitts are clear of the beams above the riding bitts; the other beams, in general as far aft as the mizen-mast, are kept about 2 feet 8 inches in the clear afunder. Between the third and fourth beams is a scuttle on each side for the top-tackle; from the seventh to the eleventh are gratings; and between the eleventh and twelfth a ladder-way for the officers. Fourteen and fifteen are placed about 1 foot 10 inches on each side the centre of the mizen-mast; and the thirteenth 3 feet 6 inches before fourteen, so as to receive the tenons of the steering-wheel stantions in the middle; the twenty-fourth beam is so placed as to receive the tenons of the munion of the screen-bulk-head, and sometimes rounds aft for the bulk-head to follow the round-aft of the stern, or nearly so. Against the fore-side of the stern-timbers, and scored aft into them, is a transom like the deck below, but having a balcony: the deals run aft to form the same.

The *fore-castle beams* should be four more in number than there are in the upper deck, in the length of the fore-castle; and where a wide opening occurs, such as the mast-room, a half-beam should be introduced, to make good the deficiency. The cat-beam is so placed that the stantions of the beak-head-bulk-head may face on the fore-side  $1\frac{1}{2}$  inch; and when the cat's-tail comes in upon the fore-castle, and is secured thereon, it must be three-feet sided, as it requires a rabbet of five inches on the aft-side to receive the ends of the deals; but of late years the cat's-tail comes in under the beams, which greatly afflicts the conversion of the cat-heads, and makes more room on the fore-castle, and consequently the beam need be no larger than the others, whereby a great weight is taken off this part of the ship. Between the first and second beam is a ladder-way about three feet in the clear. The third beam is two feet before the centre of the fore-mast; the fore-top-fail-sheet-bitts come on the fore-side, and the heels upon the upper deck. The fore-side of the fourth beam is three feet abaft the centre of the fore-mast, which allows for the fore-jeer bitts to come on the fore-side of the beam; and their heels should cast outwards sufficient to lead the fore-tack aft clear of the galley. From the sixth to the eighth beams are the gratings over the galley; on the fore-side of the ninth beam is the scuttle for the fire-bearth funnel; between that and the tenth, the steam-grating over the boiler; and on the after-beams was a cupola, or belfry for the bell, but that of late has been removed to the fore-part of the quarter-deck, between the main-top-fail-sheet-bitts, in the royal navy.

The *round-house beams* are smaller than those of the quarter-deck; therefore, let the number of beams on the round-house be two, or more, in number than in the same length of the quarter-deck. The round-house should always have a great round-up, both for strength and convenience.

With regard to placing the round-house beams, we have only to attend to the foremost stantion of the steering-wheel, so as to receive the tenon at the head: the mizen-mast must also have a beam about 20 inches on each side the centre,

## SHIP-BUILDING.

centre. Before the mast is a small pair of bitts for the mizen-topfail-sheets; and over the middle of the captain's lobby is a companion with glafs-fashes; but lately illuminators of glafs are let into the deck, which are found more convenient. The intermediate beams may be placed equally distant afunder, letting the beam over the screen-bulk-head have a proper round-aft, agreeably to the quarter-deck beam underneath.

The beams of the several decks, as taken from the sheer-plan, *Plate I.*, being described, those of the orlop only remain: therefore, fet down from the upper side of the gun-deck beams 7 feet 1 inch, for the upper side of the orlop beams; but as the platforms forward and abaft are laid with three-inch deal or plank, they may be kept so much below the range of the other beams, that is, from forward to beam number six, and from the twentieth to the after-beam, which is immediately under the twenty-seventh beam of the gun-deck.

The beams of the orlop round-up  $2\frac{1}{2}$  or 3 inches in midships, and should be placed directly under those of the gun-deck, except the second beam from forward, which may be equally spaced between the first and third. Between the tenth and the eleventh beams is shewn the capitan-step, &c. for lowering the fore-jeer capitan down on the orlop occasionally; but this has been left off in the navy some years. The fifteenth and sixteenth beams take the well-bulk-heads; and till of late years the well was inclosed by a loover-board bulk-head from the orlop to the gun-deck, but is now only laid over with gratings. Between the twentieth and twenty-first is a hatch to the spirit-room; and between the twenty-second and twenty-third, a hatch to the coal-hole.

Below the orlop are the works in the hold: such are the breast-hooks from number one to six; the step of the fore-mast being made by the fifth and sixth hooks, and framed by carlings. These hooks stand square with the body, but the hooks under the gun-deck and upper deck lay with the sheer of the deck; there is likewise a hook under the hawse-holes. The magazine and light-room extend from the aft-side of the first beam of the orlop to the aft-side of the sixth, which takes the heels of the after-riding-bitts. Next abaft the magazine-bulk-head are store-rooms to the aft-side of the eighth beam; and under those a shot-locker. Clofe abaft the main-hatchway is the pump-well, inclosed with a bulk-head of three-inch plank, about ten feet fore and aft, and eight feet athwartships in the clear. In the well is the step for the main-mast, and the pumps on each side; and adjoining the well, on the fore and after-sides, are shot-lockers about two feet in the clear. On the fore-side of the twentieth beam is the bulk-head of the spirit-room, which extends to the aft-side of the twenty-second beam; and on the fore-side of the twenty-third beam is the after-bulk-head of the coal-hole, and fore-part of the powder-room, which extends to the after-side of the twenty-fourth or after-beam. The orlop cannot extend further aft, or sufficient space would not be left for the bread-room. On the fore-side of the after-beam of the gun-deck is a bulk-head, which terminates the bread-room; and the space abaft it to the transoms is called lady's-hole. Clofe before the powder-room-bulk head is a crutch; and two more crutches are spaced abaft the powder-room.

In the profile, *Plate IV.*, is represented the method of connecting the sides and beams together by knees and riders, as used when that plate was engraved; but owing to the great scarcity of knee-timber since that time, other methods of connecting the sides and beams together have been adopted, which will be more noticed hereafter, under the

head of *improvements and projected improvements in the building of ships.* See *SUBSTITUTE.*

Hanging and lodging-knees of wood of a kindly growth is certainly the best mode of connecting the sides and beams together. The addition of breadth and top-riders, particularly in wake of the masts, and three or four in the waist, where they rake much, and so cross several of the timbers, must certainly stiffen the side; but this may be more necessary in repairs than in new ships, if the hanging-knees are of a good growth, as before observed: but by no means to dispense with a hanging-knee to introduce a rider, but only when they can clear each other, as the gun-deck beam fifteen and upper deck beam fourteen, then it may be allowed to be very strong. Observe, whenever a rider comes in the throat of a lodging-knee, it can only be made of iron.

*In the hold* it is customary to place four floor-riders, one under the beam at the aft-side of the fore-hatchway, and the after one under the beam abaft the main-mast; the next under the beam before the main-mast, and the other midway between that and the fore-hatchway. The floor-riders extend about twelve feet on each side beyond the keelson, and about one foot four inches square.

*Lower futtock-riders* are from five to six in number, one on the side of each floor-rider, and one or two abaft the after floor-rider. Their length is from the side of the keelson, to give about eight-feet shift to the

*Second futtock-riders*, which extend from the floor-rider head up to the under side of the orlop-beam, and are about one foot two inches square.

*Third futtock-riders* are in length from the head of the lower futtock-rider to the under side of the gun-deck beam, and score on to the side of the orlop-beam  $1\frac{1}{2}$  inch with a dove-tail, and are in size the same as the second futtock-riders. Observe, in shifting the riders, that they come clear of the pumps and of each other, otherwise they must cast sideways, as at the nineteenth beam of the orlop.

A long carling 14 inches deep and 12 inches broad, is scored up two inches on the under side of the six after gun-deck beams, or to the beam before the mizen-mast, and connected to the sternson-knee by an iron plate on each side at the after-end, the bolts being driven through and clenched on each plate alternately.

The inboard works being described in profile on the several decks, it is necessary also to represent them on the plan of each deck.

*Instructions for designing the Plans of the Decks.* *Plates V. and VI.*

Transfer from the sheer-plan, *Plate I.*, the heights of each deck at the side, at every timber, to its corresponding timber in the body-plan; then upon each plan draw a middle line, and therefrom square up the stations of all the timbers, as taken from the sheer-plan. Next transfer from the body-plan the half-breadth of each timber at the height of the deck intended to be drawn, and set them off on each side the middle line, at its corresponding timber and plan; but in *Plates VI. and VI\**, half the deck only is represented; then transfer from the sheer-plan, where the deck intersects the aft-side of the stem and stern-post at the rabbet, as in *Plate VI.*, and on those lines set off half the thickness of the stem and stern-post. A curve drawn through the half-breadths as set off, ending in the rabbet afore and abaft, will represent the outside of the timbers; then within that line set off the moulding of the timbers, and drawing another curve thereto, gives the boundary of the deck at the side, and determines the length of the beams.

Upon

## SHIP-BUILDING.

Upon each plan square down the sides of the ports and beams, and centres of the masts and capstans, from the profile, *Plate IV.*

Thus far the plans of the decks are general; but as each deck is very differently fitted, it is necessary to have a half-plan of all at least, and what little difference there may be on the opposite side, let the explanation suffice.

In the plan of gun-deck, *Plate V.*, is shewn not only the upper sides of all the beams, and the method of tabling them together in two or more pieces, as then customary, but now douelled instead of tabled; those in midships, being the longest, are made of three pieces; and those where they are shorter, as at the twenty-sixth beam, are in two pieces: those in three pieces have the middle piece scarfed to each arm. The method of connecting the sides with hanging and lodging-knees is likewise shewn in this plan, with the iron lodging-knee behind the rider, (engraved hanging by mistake,) as at the fifteenth and sixteenth beams. The beam-arms at the main-hatchway and mast-rooms are represented as tabled into their adjoining beams, the seventeenth and eighteenth. The framing of the deck to receive the flat having three tier of carlings, nearly all fore and aft, with a sufficient number of ledges let into them parallel with the sides of the beams, is also represented here. The framings in the middle are the mast-partners; those for the fore-masts to be formed by the standard against the fore-side of the fore riding-bitts, the inside of which must be kept half the diameter of the mast, and five inches more for the wedging, and to extend from the bitts to the step of the bowsprit: the cross-locks, which frame the mast-hole athwartships, are to be eight inches thick, and kept at the same distance on each side the centre of the mast, and rabbet into the partners: the mast-hole is made eight square, but now circular, by corner-pieces rabbetted to half their thickness into the partners and cross-locks: on the fore-side of the fifth beam is a cap-scuttle about two feet square, and another abaft the sixth beam for handing up cartridges, &c. from the magazine. The fore riding-bitts are 1 foot 8 inches square, and placed four feet asunder, or two feet on each side the middle line: the after riding-bitts are of the same size, and placed 4 feet 6 inches asunder, and the standard against their fore-sides extends to the fore riding-bitts: the cross-pieces abaft the riding-bitts are 1 foot 6 inches fore and aft, and two inches less deep, and the face-pieces on their aft-sides are of elm six inches thick. The framing of the fore-hatchway and ladder-way consists of coamings 1 foot 6 inches above the beam, that is, the lower piece to be 9 inches deep and 10 inches thick, and the upper piece 9 inches deep and 7 inches thick, douelled together, and spread in the clear 4 feet 8 inches; and the head-ledges to be 7 inches thick, scored and tailed into the coamings, and to round-up above the latter, after the rate of  $2\frac{1}{2}$  inches in six feet of length. The capstan-partners are here framed as on the upper deck; but as this method of lowering the fore-jeer capstan is discontinued, let it be framed as the main-jeer capstan. The main-mast partners are framed similar to the fore partners, the carling being 1 foot 5 inches broad, and 1 foot 6 inches deep. The chain-pumps are represented on the plan as fitting the pump-cases through the mast-partners, and the back-ropes without; the sprocket-wheel and spindle-work in brass rhodings or gudgeons, let into the top-fail-sheet and jeer-bitts, and the winches also in the pump-pillars. The main-hatchway is 6 feet 4 inches athwartships, and fitted with coamings and head-ledges as the fore-hatchway. The after-hatchway is the same as the fore-hatchway. The step for the main-jeer capstan is 1 foot 10 inches broad, and 1 foot 6 inches deep, to be scored down between beams 21 and 22, and lap thereon 8 inches above the beam, with

broad carlings on each side to receive the bolts of the pall-rim: in the middle of the step is an iron cap to receive the spindle. The hatch to the spirit-room, and ladder-way to the cock-pit, are framed as the fore-hatchway. The mizen step to be 1 foot 8 inches broad, and 1 foot 4 inches deep, and scored down between beams 25, 26, and 27, two inches. The bread-room scuttle, which is 2 feet 4 inches square, is on the larboard-side, and is framed with coamings and head-ledges, with a cap or top as high above the deck as at the hatchways: on the starboard-side abaft is a scuttle about two feet square over lady's-hole, and another 14 inches square over the scuttle to the magazine. On the gun-deck, in the middle of the three or four after-beams, is a standard, sided 12 inches, the upper end to lay against the transoms, as high as the helm-port transom.

A strake without the coamings at the main-hatch is represented, the binding-strakes all fore and aft, which are to strengthen the decks, as they are weakened by the hatchways, therefore the butts should be shifted clear of them: in the inner strake are driven the stopper-bolts. Forward is shewn the moulded size of the deck-hook and eaking, also the plan of the hawse-holes and manger, with the stantions.

On the same plate is drawn the plan of the orlop, with its several conveniencies. On the fore-platform, which extends from the fore-peek to the fore-hatchway, is the boatwain's cabin on the larboard-side, with such another for the carpenter directly opposite; and before each is a store-room, to hold their respective stores; before the boatwain's store-room is a sail-room: between the fore riding-bitts are two doors, one leading to the light-room passage on the larboard-side, and that on the starboard-side to the magazine and gunner's store-room. Close before the heel of the larboard foremost riding-bitts is a cap-scuttle, inclosed, to hand up filled cartridges; and on the opposite side a flat scuttle to the magazine, likewise inclosed: at the end of the light-room passage is a scuttle to the light-room: abaft the riding-bitts are scuttles to the boatwain's, gunner's, and carpenter's store-rooms under the orlop. The fore-hatchway is of the same size, and immediately under that on the gun-deck, but has only a flat framing round it, to take the hatches that cover it. The beams of the orlop are rabbetted on each edge to receive the flat, which is only oak boards  $1\frac{1}{2}$  inch thick as far as the after-platform. The midship sail-room now extends from the main-hatchway to the fore-hatchway, and is framed round with pillars upon a carling ten inches deep; and as the capstan-room is not used, the gunner's cabin is made at the fore-part. The main-hatchway is of the same size as that over it, and is framed round as the fore-hatchway. The well is not inclosed, as shewn on the plan, but at present is laid over with gratings. The after-hatchway is of the same size as the hatch over it, and framed like the others. Between the beams 21 and 22 is a double hatch to the spirit-room, and one next abaft it to the coal-hole. On the fore-side of beam 23 is the bulk-head of the cock-pit, and abaft it inclosed are two scuttles, one to the powder-room the other to the light-room.

On the larboard-side abaft is the steward's room, abaft which is the bread-room; and the interval between the steward's room and light-room bulk-head is the steward's bed-place and racks for stowing cheese: next before the steward's room is the purser's cabin, before that the stow-room, and next to that a compartment for the marines' clothing. From the steward's room, to nearly forward on each side, are the wings, or an open space about 4 feet 6 inches from the side, sufficient to swing a mall, if necessary, to plug up shot-holes in the time of action. From the steward's room to the marines' clothing

## SHIP-BUILDING.

is birthed up with a bulk-head of  $1\frac{1}{4}$ -inch deal, and the same from the boatwain's cabin forward, and between those with stantions and whole deal battens or lattice-work. On the starboard-side, opposite to the steward's room, &c. is the captain's store-room, doctor's cabin, and first lieutenant's store-room; and between the captain's store-room and passage to powder-room, is fitted a dispensary for the doctor.

On this plan it is customary with a different coloured ink to draw the plan of the works in the hold; and to distinguish them on the plate, they are represented by fine ticked lines.

Under beam 1 is a bulk-head for the boundary of the light-room, together with its plan, and also the magazine-lights, jambs, and splan-boards, (to throw the rays of light more into the magazine). The magazine is surrounded by a strong bulk-head of three-inch plank, the edges rabbetted together, the inside of which is doubly lined with slit deal, so as to cover each joint, and on the outside with slit deal, and a thick coat of mortar under it. The flat of the magazine is first laid with three-inch plank, caulked on beams underneath, upon which are fastened, with copper dumps, the pallating beams, framed together at right angles, about three feet asunder: the upper edges are rabbetted to receive the flat, which is  $1\frac{1}{2}$ -inch deal, lined on the under side. The bulk head at the side, which forms the wing, is constructed with pannels, and rabbetted stantions to receive the pannels: in the fore part of the magazine in midships is the filling-room, which is lower than the surface of the flat about twelve inches: this is lined with lead, as it is the place where the cartridges are filled, (hence its name,) for greater security: as it is close abaft the lights, glass fastnes extend across, guarded with a copper-wire net-work: in the sides of the filling-room are racks for filled cartridges, and a compartment behind them for staves of empty barrels. The powder-barrels are stowed upon dunnage battens, over the pallating flat, which is parted off from the filling by an open bulk-head of stantions and battens. Magazines are now only fitted up to receive barrels with cartridges already filled.

Abaft the magazine are a store-room for the boatwain; on the larboard-side, in midships, a store-room for the gunner, and under that a shot-locker; and on the starboard-side a store-room for the carpenter.

Next abaft the main-hatchway is the plan of the well, and shot-locker afore and abaft it. Under the fore-side of the 20th beam is the bulk-head of the spirit-room, and under the aft-side of the 22d beam the bulk-head of the coal-hole: its after bulk-head is under the fore-side of the 23d beam, which also makes the fore bulk-head of the powder-room, which is inclosed round with a bulk-head similar to that of the magazine forward; likewise the light-room, and passage to the powder-room, which is fitted up with racks for stowing filled cartridges, as represented in the plan: all abaft the powder-room bulk-head is occupied for the bread-room, to the bulk-head for lady's-hole.

On *Plate VI.* is represented the half-plan of the quarter-deck, waist, and forecattle, likewise the half-plan of the upper deck.

On the plan of the upper deck is shewn the beak-head stantions, whose sides are rabbetted to receive the bulk-head: the midship stantions to be about 2 feet 6 inches on each side the middle line, and 12 inches square as high as the flat of the beak-head; they tenon at the heel into the foremost beam of the upper deck, and receive into their outsides the tenon of the collar-carling, which is of the same size as the stantions, having its upper side well with the flat of the beak-head, which is of the same height as the lower sills of the ports. The midship stantions to be  $6\frac{1}{2}$  inches square above the

collar-carling: the other stantions, which are four in number on each side, are all  $6\frac{1}{2}$  inches square, and face aft  $\frac{3}{4}$ ths of an inch into the cat-beam: the two outer stantions are placed asunder to the spread of the round-houses, and should be kept far enough out that the funnel may come clear of the side: the third stantion from the middle line must be spaced so as to make the bow-chafe port: the next stantion within makes the head-door: on the midship-side of the head-door is a scuttle, with a flap hung over it to lead in the fore-tack. The heels of all these stantions tenon into the collar-carling with a double-stop.

The framing of the fore-mast partners are shewn, as before directed, for the main partners on the gun-deck, on the outside of which are the heels of the fore-sheet and jeer-bitts; the heel of the former to spread sufficiently from the middle line to lead the fore-tack clear of the galley, having a sheeve fitted into it for that purpose. Abaft the fore-mast partners are the cants for the galley, which is inclosed abaft by two doors.

The fore-hatch and ladder-way to be framed, as directed on the gun-deck, with coamings ten inches broad, and nine inches above the deck, and head-ledges six inches thick; next abaft are the fore-jeer capstan partners, to be seven inches thick, their ends let down into a framing similar to the hatchway (or to have their ends square, and shut in with the deck), and bolted through the beams and carlings, and their edges to be rabbetted to stop the caulking. The ladder-way, main hatchway, main-mast partners, after-hatch, main-jeer capstan partners, gratings, and ladder-ways, are all framed as before described.

On this plan the flat of the deck is represented, and the several butts shifted: close to the side are the water-ways, five inches thick, and the first strake of oak, which is cut off between the riders; the next four strakes are also English oak in the wear of the guns, shifted in short lengths, and anchor-flock, or top and butt, to assist the conversion. The rest of the deck is three-inch Prussia deal, except the binding-strakes, which are the second and third, without the main hatch-coamings, and under the forecattle: the deals must be so shifted as to work their whole lengths, or great waste will occur, that is, 30, 36, and 40-foot lengths. The mizen partners are framed with a carling on each side, and corner-pieces as high as the beams, and the flat round them is oak, five inches thick.

Close up under the beams is represented the tiller, as fitted with the horn-hoop over the end, for keeping up the tiller-ropes in the sweep, and a hoop abaft it, with eyes in it, through which the rope is reeved, to be set up taught by tackles hooked to the eye-bolts; further aft, at the after-end, are iron rods, which are hove taught by a screw-nut, to keep the tiller aft. At the fore-end, on the upper side, is an iron gooseneck, which traverses on the sweep, and keeps up the fore-end; the rope traverses round the sweep in a groove, and is led up to the wheel on the deck above by sheeves fitted at the end of the sweep, and the blocks afore the mast represented by the ticked line.

Sometimes abaft, where the side is to round to have riders, iron standards are fitted, as on beams 26 and 27.

On the beam, before the mizen-mast, is the bulk-head of the ward-room, fitted with double doors on each side.

The knee under the cat-beam prevents the hanging of a door at the aft-side of the round-houses forward: they are therefore inclosed with a bulk-head, and a door on the aft-side.

On the plan of the forecattle is shewn (as was the practice when the plate was engraved), the construction of the life-rail, as let over the heads of the beak-head-stantions,

with the chafe-port and upper part of the round-houses; also the plan of the cat-head, cat's-tail, and the knee abaft the cat-head. Between the cat's-tail and the fore-mast is framed in midships a ladder-way, and round the fore-mast are the fore-top-fail-sheet and jeer-bitts, with their cross-pieces; on the sides of the bitts the cheek-blocks, or they must be provided very large, to receive all the sheeves necessary for sheets, braces, &c. Abaft the fore-mast, on each side, is a scuttle for the top-tackles to lead through to hook to an eye-bolt on the upper deck. Over the galley, in midships, are framed the steam-gratings; and between them coamings for the chimney-funnel. At the aft-part of the forecastle are represented the belfry bitts, with the knees to support them; and over the breast-beam are shewn the foot-rail and stantions, as then used, but now discontinued.

Along the waist into the side, instead of gang-boards, as formerly, the deck is continued from forward to aft seven feet three inches from the side; likewise the flat is continued along the midships, five feet three inches on each side the middle line, except an opening over the main-hatchway.

Upon the plan of the quarter-deck is shewn the plan of the breast and foot-rail over the breast-beam, with their stantions, now rendered unnecessary by continuing so much of the deck along. On each side of the main-mast is a flat scuttle for the pumps to be passed through; and on the aft-side of the beam abaft the mast are the brace-bitts. Abaft the brace-bitts, on each side, is a flat scuttle, for leading through the main top-tackles to an eye-bolt driven in the upper deck. From the seventh beam to the twelfth the space is framed for gratings, and a ladder-way, as before directed, five feet four inches in the clear. Between the fourteenth and fifteenth beams are fixed the steering-wheel and its stantions; in the next opening is the mizen-mast: the partners are formed with thick-stuff, as at the upper deck. On the beam abaft the mast is the bulk-head of the lobby and bed-place; and on the twenty-first beam the bulk-head of the captain's cabin: between these bulk-heads are a fore and aft bulk-head that part the lobby and bed-place; and on the twenty-fourth beam is the foreen-bulk-head. The latter is unnecessary when there is no walk or balcony abaft.

A plan of the round-house is not wanted, as, besides its beams and ports, there are only the mizen-top-fail-sheet-bitts on the fore-side of the beam before the mast, and taffrail-knees abaft: when an open stern, illuminators instead of a companion are let into the deck.

*Explanation of the Methods of Laying-off all the Parts of a Ship on the Mould-loft Floor, preparatory to the actual Building of the Ship.*

The sheer draught, *Plate I.*, being completely drawn upon paper, mostly to a scale of a quarter of an inch to a foot, as before observed, or forty-eight times less than the real size of the ship, it remains to expand it to that size on the mould-loft-floor; but the latter is seldom long enough to admit the laying-off of any large vessel in one length; in small mould-lofts they must of course lay-off in three or four lengths. Indeed, to lay-off in one length would cause unnecessary waste of time; for many of the joints of the timbers, or perpendiculars of the fore-body, answer alike for the after-body.

*Laying-off.* *Plate VII.*

*Plate A* may be said to represent the mould-loft-floor in miniature, by the same scale as *Plate I.*; but here, to prevent confusion, the different plans are shewn separate, but

on the floor in the grofs: the several plans are laid off one over the other, which, to the practitioner, is perfectly clear.

The mould-loft-floor being cleared, begin by striking a straight line from one end to the other, as *AA* in the above plate, in distance from the side of the loft as much as the keel is deep. This line will represent the upper edge of the rabbet of the keel in the sheer-plan, *fig. 1*, above which all the heights are to be set up, and it will represent also the middle line of the half-breadth plan, *fig. 2*.

Proceed now to lay-off the fore-body, by transferring from the sheer-plan, *Plate I.*, and erecting from the line *AA*, to the right-hand, the several perpendiculars or joints of the frames  $\oplus$ , *B, D, F, H, K, M, O, Q, S, U, X*; and the fore-mast-perpendicular, and likewise frames *2* and *4* abaft  $\oplus$ . This must be accurately done, so as not to exceed the room and space.

Now describe the stem, as in *Plate VII. fig. 1*, supposing it of the full size, by setting up from the line *AA* the height of the centres from *Plate I.*, and the nearest distance thereon from the adjoining perpendicular, as at *Q, Q*; by which radius the fore and after sides are swept, likewise the rabbet in the middle, from the keel upwards to *S*. Then set up the height of the head, or upper part, and its distance forward from the nearest perpendicular; then, by pinning a batten to the spots last set off, and to the curves already swept, the stem will be formed likewise.

Transfer from the sheer-plan, *Plate I.*, the heights of the lower and upper height of breadth-lines from the line *AA*, as in *Plate VII.*, from the perpendicular *4* to the stem; then, by pinning a batten to those heights, produce the fair curves *E* and *F*.

Let the outlines of the fore body-plan, *Plate VII. fig. 3*, be represented, that is to say, the middle line by the line *AA*; the base line, or upper edge of the keel, by one of the perpendiculars; then will the outside line, *RL*, be parallel to the line *AA*: at the moulded breadth at dead-flat (as few mould-lofts are broad enough to admit the height of the timbers as in the plate,) strike in the half-siding of the stem *S* from the middle line.

The main half-breadth line may now be laid off, by transferring it from the half-breadth plan, *Plate I.*, to its corresponding timbers on the floor, from the line *AA*; and to end this line at the stem, take the height in the sheer-plan, *fig. 1*, where the lower height of breadth-line intersects the aft-side of the rabbet of the stem, and transfer it to the middle line of the body-plan, *fig. 3*; and from thence take the half-thickness of the stem, and set it up from the middle line of the half-breadth plan upon a line squared down from the aft-side of the rabbet of the stem, at the lower height of breadth in the sheer-plan. Then, by pinning a batten to the several half-breadths set off, and to its ending at the stem, we form the fair curve *D*, as in *Plate VII. fig. 2*, or main half-breadth line.

Observe, when the batten is pinned, to look along it strictly, and see that its edge produces a fair line: this must be always understood, and therefore need not be repeated.

Transfer from the sheer-plan, *Plate I.*, the heights of the centres for the radius of the floor-sweeps of the fore-body on to the floor, and by pinning a batten thereto, produce the line *B*, in *fig. 1*.

Transfer from the half-breadth plan, *Plate I.*, the rising half-breadth, or narrowing of the floor-sweeps of the fore-body, and by pinning a batten thereto, produce the line *B*, in *fig. 2*.

Transfer from the sheer-plan, *Plate I.*, the heights of the top timber-line to the floor; and should the floor not be broad enough to admit the whole heights, set them up their

their respective timbers from some straight line, as A A, allowing the addition of twenty feet; then, by pinning a batten to those heights set up, produce the curve I, *Plate VII. fig. 1.*

Transfer from the half-breadth plan, *Plate I.*, the top-timber half-breadth on to the floor, and by pinning a batten to the several half-breadths set off, the curve C, in *Plate VII. fig. 2.*, will also be represented.

Then, having marked the several lines laid off with their respective names, proceed to lay-off the fore-body, fixing on some convenient part of the floor, making the line A A, *Plate VII. fig. 1.*, serve for the middle line M, *Plate VII. fig. 3.*, and one of the perpendiculars for the base line, or upper edge of the keel, as before observed. The diagonal lines in the body-plan are not only used in laying-off the body on the floor, and taking the bevellings of the several timbers, but are of very principal use in the actual building; for at their stations the ribbands and harpins, which keep the whole frame of the ship together until the planking is brought on, their situation with regard to the heads of the timbers must be determined; it consequently follows, that a particular explanation of them is necessary.

The floor-head diagonal marked C in *Plate VII. figs. 3* and 5, terminates the length of the floors, hence its name. The placing of this diagonal is of the utmost consequence to the strength of the ship, it being so near the bidge, or that part which takes the ground, that it consequently is always liable to the greatest strain. It should, therefore, be placed as much above the bearing of the body in midships as can be conveniently allowed by conversion of the timber; but, afore and abaft, it is not of so much consequence. Bevellings are taken at this diagonal to as far forward and aft as the floor extends.

The diagonal marked B in *Plate VII. figs. 3* and 5, is placed in midships from eighteen inches to two feet, according to the size of the ship, below the floor-head C; it is the station where the floor-ribband is placed in midships, and likewise the floor-harpin forward. Bevellings are also taken at this diagonal, all fore and aft, from which it is termed the *floor-ribband*.

The lower diagonal, marked A in *Plate VII. figs. 3* and 5, is situated generally in the middle between the keel and floor-ribband; at which place the lowest bevellings of the timbers are taken.

The diagonal marked D in *Plate VII. figs. 3* and 5, is situated in the middle, between the floor-head and first futtock-head, at which place a ribband and harpin are necessary for the security of the first or lower futtocks, and hence called the *first futtock-ribband*. There are also bevellings taken at this diagonal, all fore and aft; which, being the part of the body where the timbers most vary, occasion them to be the greatest bevellings in the whole body.

The diagonal marked E in *Plate VII. figs. 3* and 5, terminates the heads of the first futtocks, and is therefore called the *first futtock-head*: it should be spaced about seven feet above the floor-head, in order to give sufficient scarf or shift to the lower part of the second futtocks. Bevellings are likewise taken at this diagonal, all fore and aft.

The diagonal marked F in *Plate VII. figs. 3* and 5, is situated in the middle, between the first futtock-head and the second futtock-head, at which place a ribband and harpin are necessary for the security of the second futtocks, and hence called the *second futtock-ribband*. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked G in *Plate VII. figs. 3* and 5, terminates the heads of the second futtocks, also the heads

of the double futtocks afore and abaft the floors, and is therefore called the *second futtock-head*; it should be spaced about seven feet above the first or lower futtock-head, in order to give sufficient scarf or shift to the lower part of the third futtocks. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked H in *Plate VII. figs. 3* and 5, is situated in midships in the middle, between the second futtock-head and the third futtock-head, at which place a ribband and harpin are necessary for the security of the third futtocks, and hence called the *third futtock-ribband*. Observe, the harpin is placed low enough at the stem that the wales may be worked before it is taken down, or it may fly up like the others, and not come home to the stem. Bevellings are also taken at this diagonal, all fore and aft.

The diagonal marked I in *Plate VII. figs. 3* and 5, terminates the heads of the third futtocks, and is therefore called the *third futtock-head*, and should be spaced about seven feet above the second futtock-head, so as to give the same shift to the fourth futtocks as the other futtocks have. Observe, such third futtocks as come under the gun-deck ports, must be continued upwards to the under part of the ports, if possible to be gotten. Bevellings are also taken at this diagonal, fore and aft.

It must be observed, that the diagonals for the ribbands, as above described, must all be drawn in pencil on the body-plan, *Plate I.*

A ribband and harpin are also placed all fore and aft below the gun-deck and upper deck ports, and one likewise at the top timber-line, as at M, N, and O, *Plate VII. figs. 3* and 5, which, with the ribbands and harpins before mentioned, keep the whole framing of the ship together to its true model.

Having described the diagonals, and struck them across the fore-body on the floor, as in *Plate VII. fig. 3.*, the several timbers may be completed, by first transferring the lower height of breadth-line E from the sheer-plan, *Plate VII. fig. 1.*, from  $\oplus$  to X, to the fore body-plan, *fig. 3.*, and striking horizontal lines at each of those heights across the body-plan, as at K; then transfer the main half-breadth of each timber from the half-breadth plan, *fig. 2.*, upon their corresponding heights from the middle line of the body-plan, *fig. 3.* Then by taking the radius or length of the lower breadth sweep from the fore body-plan, *Plate I.*, of timber dead-flat, set it off upon its lower height of breadth line, and it will sweep it downwards nearly as low as the second futtock-head: in the same manner, proceed with all the timbers to Y.

Take off the half-breadths of each timber in the fore body-plan, *Plate I.*, from the middle line on the diagonal floor-ribband, as far forward as X, and set them up from the middle line of the half-breadth plan, *fig. 2.*, upon their respective timbers; then, to end it at the stem, transfer the height where it intersects the half-thickness of the stem in the body-plan, *fig. 3.*, to the fore part of the rabbet of the stem in the sheer-plan, *fig. 1.*; from thence square it down to the middle line of the half-breadth plan, *fig. 2.* Take the half-thickness of the stem in the body-plan, *fig. 3.*, on the diagonal, and set it up from the middle line of the half-breadth plan, *fig. 2.*, upon the line last squared down; and from thence sweep an arc the thickness of the bottom plank taken on the diagonal, the after part of which arc is the ending of the fore part of the floor-ribbands. Then, by pinning a batten to the several half-breadths, and to the back of the arc or ending, the floor-ribband will be laid off.

In the same manner proceed with the ribbands or diagonals

D, F, and H, *fig. 3*, as you find ticked from  $\Phi$  to the stem in the half-breadth plan, *fig. 2*, to their respective diagonals in the body-plan, *fig. 3*.

Set up 11 feet from the base line in the body-plan, *figs. 3* and *5*, and strike a line parallel thereto, which is the height of the centre of the floor-sweep at dead-flat. Then take the heights in the sheer-plan, *fig. 1*, for the centre of the floor-sweeps B, from B to K, and set them up in the body-plan, *fig. 3*, above the centre at dead-flat, and at each height strike level lines. Then take the half-breadths in the half-breadth plan, *fig. 2*, of the centres of the floor-sweeps B, and set them off on their corresponding heights from the middle line in the fore body-plan, *fig. 3*. Then, with a radius at the centre in the body-plan, to its corresponding half-breadth on the diagonal floor-ribband, sweep the curves of the several timbers at the floor-head, from  $\Phi$  to K.

Having swept in the various curves below the lower height of breadth, and at the floor-heads, pin a batten to the half-breadths, as set off on the diagonals for dead-flat, and the back of the above sweeps; continue it with a small curve or hollow from the sweep at the floor-head to the rabbet of the keel, which completes that timber from the lower height of breadth to the keel. The same process will complete all the timbers. With regard to the heeling of the timbers exactly, set off the half-thickness of the keel from the middle line in the body-plan, *fig. 3*, on the base line, and parallel thereto to its depth; then with compasses, opened to the thickness of the bottom plank, sweep two arcs, so as to form the triangle at the outside on the upper edge, and it will be readily seen that the timbers along the midships will end at the outside of the rabbet; but as they approach forward, they will end on the inside of the rabbet; and as the keel tapers at the fore-end, they must be heeled sufficiently within the keel to admit the thickness of the plank: then to heel the timbers that rise on the stem, transfer their heights where they cut the outside of the rabbet of the stem in the sheer-plan, *fig. 1*, to the half-thickness of the stem in the body-plan, *fig. 3*; from thence, with compasses opened to the thickness of the bottom plank, sweep an arc inwards, the back of which is the ending of the timber, and a line squared from the timber to the height set off on the outside of the stem represents the rabbet in that direction.

The fore-body being completed below the lower height of breadth, the upper part, or top-side, may be laid off by transferring the upper height of breadth line F from the sheer-plan, *fig. 1*, at each timber from dead-flat to X, to the body-plan, *fig. 3*, and striking level lines across at each height. Continue upwards each timber parallel to the middle line, from the lower to the upper height of breadth. Then, with the radius of the upper-breadth sweep taken from the body-plan, *Plate I.*, sweep upwards every timber from its respective upper-breadth line, from dead-flat to O.

Transfer the height of the top timber-line I, from the sheer-plan, *fig. 1*, at every timber, to the fore body-plan, *fig. 3*, and strike in level lines at every height; then take the top-timber half-breadth from the half-breadth plan, *fig. 2*, at every timber, from dead-flat to X, and set them off from the middle line of the body-plan, *fig. 3*, upon their respective heights. Then, by a mould made to the hollow or tumbling-home of the top-side, and upper-breadth sweep at dead-flat, and a few feet above the top-timber-line, every timber from dead-flat to O may be formed on the floor by lowering or raising the mould so as to agree with the upper-breadth sweep, and the half-breadth, as set off on the top timber-line. But the timbers before O must gradually per-

take of the hollow of top-timber X, which falls outwards considerably from a perpendicular at its main-breadth, though parallel to the middle line above the height of the top timber-line to the top of the side, which must be transferred from the sheer-plan, *fig. 1*, to each timber respectively in the body-plan, *Plate VII. fig. 3*. Pin a batten to those several heights, which will form the curves O and P, as in *fig. 3*. Take square from the middle line in the body-plan, *fig. 3*, the half-breadths of all the timbers at the top of the side, and set them up on their corresponding timbers from the middle line in the half-breadth plan, *fig. 2*; seeing that it makes a fair curve. The fore-body may now be said to be laid off above the main-breadth, which completes the whole of the square fore-body, *fig. 3*.

The correct height of the knuckles of the timbers at the beak-head requires some attention; for if they were carried too high, the sheer of the ship must be lifted; or, if kept too low for the sheer, the timbers must be reduced to raise the knuckles: therefore determine what part of the sheer-strakes shall come well with the knuckles; for if the knuckle was to come in the middle of either sheer-strake, the fore-shaft of it must then be wrought, taking a large piece of timber and much labour. In *Plate VII.* the upper edge of the sheer-strake is well with the knuckle. Another consideration to be taken into this account is the lifting the sheer forward, that it may have the same appearance on the ship as is designed on the draught; for if not lifted gradually some inches higher towards the stem, the curvature of the bow will make it appear to drop below a fair curve.

To know how much the sheer of the ship requires to be lifted forward has sometimes been resolved in this manner. Prolong the sheer of the wale before the stem in the sheer-plan, *fig. 1*, at pleasure; then pin a batten to the round of the bow at the main half-breadth, in the half-breadth-plan, *fig. 2*, and mark on the batten the stations of the square timbers and the side of the stem; then pin the batten to the sheer of the wale in *fig. 1*, keeping the stations of the timbers, as marked on the batten, well with those near dead-flat, where they will not alter; then mark the other timbers, and the stem on the sheer of the wale line prolonged, and level them aft, to intersect their corresponding timbers and the stem; then a batten pinned to those intersections will give the curve for lifting the sheer of the ships round the bow. But as the forms of the bows of ships are so very different, it cannot be recommended as an undeviating rule, and therefore must be referred to practice; however, it is requisite to make an allowance for it in the laying-off of all ships, as the decks, sheer-strakes, and consequently the knuckles of the timbers, all partake of this necessary additional height.

The square body afore dead-flat being now laid-off, proceed to lay-off the after-body abaft dead-flat: but it is only necessary to point out such differences as occur at the extremes of the ship, the midship part being similar in both bodies.

On the mould-loft-floor it is customary to set off as many of the perpendiculars abaft the fore-body already laid off, as to have sufficient room for the stern-post, using as many of those in the fore-body as will answer to the regular room and space of the timbers, which will be as far as B, which will extend in the after-body as far as 14, consequently from 14 strike up from the line A A all the remaining perpendiculars to 36.

Strike in the aft-side of the stern-post on the floor from the sheer-plan, *Plate I.*, and the aft-side of the rabbet; and strike a line parallel thereto, on the fore-side, to the thickness of the bottom plank.

Transfer from the sheer-plan, *Plate 1.*, the heights of the centres of the floor-sweeps, lower and upper heights of breadth, top timber-line, and top of the side, as before.

Transfer from the half-breadth plan, *Plate 1.*, the half-breadths of the floor-sweeps, main half-breadth, and top-timber half-breadths. But to end the main-breadth, and likewise the top-timber half-breadth in the half-breadth plan, *fig. 2.*, the side-counter-timbers must be laid off in the sheer-plan and body-plan, and where they intersect the side-counter-timber in the sheer-plan, must be squared down to the half-breadth plan.

In the plan of the after-body on the mould-loft-floor, its middle line is made by the side-line of the fore-body, consequently the bodies at the lower part cross each other. This would have appeared very confused in the plate, but it is always a maxim in laying-off on the floor to use as few lines as possible.

The lower height of breadth and sweeps, and the centres of the floor-sweeps in the after-body, *fig. 5.*, may all be obtained exactly in the same manner as directed for the fore-body. The diagonals struck in, and the several half-breadths of the timbers set off thereon, form the after body-plan, *Plate 1.* Those timbers which come near the after-end of the keel, must be ended by setting off the half-thickness of the keel, as far as it tapers from the stern-post in the half-breadth plan, *fig. 2.*; and within the half-thickness of the keel, set off the thickness of the bottom plank. Then take off the half-breadth of each timber to the inside of the rabbet, and set it off on the base line from the middle line of the body-plan, *fig. 5.*, which is the true ending of every timber at the upper edge of the keel.

The top-side of the after-body, *fig. 5.*, is laid off in the same manner as directed for the fore-body at dead-flat, even to the after-timber.

When the bodies are thus far laid off on the floor, it is usual to make the moulds, and take the bevellings of all the timbers in the square body; that is, from O forward to 28 abaft.

#### *Moulds for the Timbers in the Square Body.*

The moulds for the midship floors are generally made first in the following manner: take fir-board, about three-quarters of an inch thick, and lay the outer edge to the floor-timber dead-flat, in the body-plan, *fig. 3.*, from the keel to the floor-head, and make it of a parallel width, about four inches. Provide another board, and lay it to the foremost square floor O, from the head to the sides of the keel, and make it of the same width. Then tack them both down in their places, and nail a piece of board made parallel to the half-breadth of the keel, its midship edge well with the middle line, and lower end cut square, and be well with the base line, or upper edge of the keel: the upper end is to extend a few inches above the cutting-down of O. Now nail a straight batten, about four inches wide, at the floor-head, from dead-flat to O; the upper edge well with the direction of the floor-head C. Let battens of the same width be nailed across, with their upper edges kept well with the floor-ribband B, and one at the lower diagonal A, and as many between as may be thought necessary. Let these battens be one inch narrower than the others, which will distinguish them, as the former shew the proper stations of the diagonals, and likewise the direction of the floor-heads. Then, upon the cross-battens must be marked the intermediate floors from dead-flat to O. There must be outside pieces and battens put together, exactly in the same manner, for the other side; and the lines for the moulding edges of the floors correctly transferred to the other side.

These two moulds may then be united together at the middle line by hinges, so as to shut together, and be more handy for use.

The cutting-down line being transferred from the sheer-plan, *fig. 1.*, to the floor, as at M, *Plate VII. fig. 1.*, take its height above the upper edge of the keel at every floor from dead-flat to O, and set them up the middle line of the mould from its lower edge, and square them across, marking each floor's name respectively. Fix one or two battens horizontally across, from the cutting-down board in the middle to the foremost floor, as braces, to preserve the mould from racking. The mould is now finished for moulding the floors of the fore-body thus far.

Now lay the blank side of the mould upwards in the after-body, *fig. 5.*, and mark thereon, as before, the moulding edges of as many of the after-floors from dead-flat as the mould will contain, and the heights of their cutting-down, which will be found to extend to 21.

Then to the floors from 22 to the after-square floor 28, another similar mould must be made.

The lower futtock-moulds are best made of seasoned board of the above thickness, the outer edge being fayed to the frame-futtock, and the inside edge to the adjoining filling, from a few inches within the side of the keel to the first futtock-head. Then when the mould is in its place, mark thereon the side of the keel, lower diagonal A, floor-ribband B, first futtock-ribband D, and first futtock-head E; or a shorter way, the diagonals numerically, 1st diag. 2d diag. &c.

But if saving of stuff and time be considered as an object, make the edges of the mould lay to the two adjoining frames, and set down spilings to the corresponding fillings at every diagonal, and also at the head and heel.

The second futtock-moulds may be next made similar to the above, from the floor-head to the second futtock-head, marking thereon the heel C, first futtock-ribband D, first futtock-head E, second futtock-ribband F, and second futtock-head G.

The third futtock-moulds may be next made in the same manner from the first futtock-head to the second futtock-head, marking thereon the heel E, second futtock-ribband F, second futtock-head G, third futtock-ribband H, and third futtock-head I.

The fourth futtock-moulds differing in their shape, and being much longer than the others, the best and readiest method is to lay this mould to dead-flat, from the second futtock-head to the top of the side, and two or three feet longer, as the heads run higher afore and abaft dead-flat. The inside of the mould towards the upper part may be made to the scantling line, but at the heel, and a few feet above it, should be made as broad as possible; so that by this one mould may be moulded nearly all the fourth futtocks in the fore-body. Lay the mould in its place at dead-flat, and mark thereon the heel G, third futtock-ribband H, third futtock-head I, lower and upper heights of breadths K and L, gun-deck port-fill M, upper deck port-fill N, top timber-line O, and top-side P.

Next place the upper part of this mould to the foremost fourth futtock, O, of the square body, and it will be found to lay from the main-breadth upwards (as it will likewise lay to all the timbers between O and dead-flat, in consequence of the radii of the upper-breadth sweeps being all of one length); then, while the mould is in this position, if it covers that part of the timber from the main-breadth downwards to the fourth futtock-heel, the fourth futtock of this timber may be moulded by this mould, as it may then be consequently marked on it; but if not, then the mould must

must be moved to the next timbers aft, placing it after the same manner, until the timber is found to which it will mould, as described above: while the mould lies well to the timber above the breadth, take its corresponding third futtock-mould, keeping the heel of the third futtock-mould well with the heel of its timber, then raise or mark its moulding edge on the fourth futtock-mould. In the same manner place it to the other timbers, marking thereon its corresponding third futtock, at the same time marking all the respective heights of the ribbands, &c. as at dead-flat. Observe, should the mould not lay towards the head of some of the foremost timbers, (as the tumble-home is less forward abaft than in midships,) measure the distance from the mould to the line of the timber on a square, and mark it on the mould; this being done to all the intermediate timbers, they may be said to be complete on that side; and when so done, it will be necessary to have a small hole bored square through the mould at every firmark, or height, upon every timber, by which means the true shape of the timbers, and places of the firmarks, may be transferred to the other side of the mould, and likewise upon the timbers when moulding.

In the same manner must be formed another mould to dead-flat for the timbers in the after-body, marking thereon all the timbers it will take. Those timbers of the square body afore or abaft the timbers already marked on the mould made to dead-flat, on account of there being more compass at the heel, may be marked upon one mould to each body, proceeding as before, only making the lower end of the mould sufficiently broad to take the most compass timbers thereon. But should the heels differ so much as to cause the lower end of the mould to be cumbersome; in that case, make moulds to each timber, as described above.

The top-timber moulds may be made in the same manner as those for the fourth futtocks, from the top of the side to the heel I, or third futtock-head.

#### *Method of taking the Bevellings of the Timbers in the Square Body.*

The moulds for the timbers of the square body being made, it is necessary to shew in what manner their bevellings may be taken; for, until then, the timbers which have bevellings cannot be cut out.

Provide a bevelling-board for the floors, in breadth as much as the floors are sided; and, in length, sufficient to take all the floor-bevellings thereon, as *Plate VII. fig. 8*. The first bevelling to be taken is from the cutting-down line for trimming the throat of the floors; but from dead-flat to floor E, they will be found to be square, or as far forward and aft as the cutting-down is parallel with the keel. They will be all represented by a square line on the board. Then, for the throating of floor F, apply the stock of the bevel to the perpendicular, or joint below the cutting-down line, and the tongue well with the cutting-down line M, as at N, *Plate VII. fig. 1*, and that will give the bevelling for the throat of floor F. Proceed in the same manner with every floor, till all those bevellings be taken and marked on the board, as *a, fig. 8*, distinguishing them by writing their respective names, as  $\Psi$  to E, F, G, H, &c. to O. These will be all standing bevellings, both in the fore and after-bodies. In the next place, the bevellings for the outsides of the floors must be taken, which are always under-bevellings in both bodies, in consequence of the floors being always placed on that side of the joint from which the body declines; these bevellings are taken at the lower diagonal *b, fig. 8*, the second diagonal, or floor-ribband, *c, fig. 8*, and floor-head *d, fig. 8*. To take these bevellings, set off the siding of each floor from its joint, or perpendicular, on each diagonal in the half-breadth plan,

*Plate VII. fig. 2*, (observing, as before, that the floors in the fore-body are before the joint, and those in the after-body abaft it,) the diagonal formed by the heads of the timbers being laid off in the half-breadth plan, as far as the square bodies, for that purpose, as at M, *fig. 2*; then take the distance of each diagonal on the siding line square from the middle line of the half-breadth plan, and set them down on their corresponding diagonals from the middle line in the body-plan, making spots in *Plate VII. fig. 3*. Then fix one leg of a pair of compasses on those spots of the lower diagonal, beginning with the first floor before dead-flat that has any bevelling, which is A, and, with the other leg, sweep the nearest distance to the line of its corresponding timber. That will determine when it is within a square in the breadth of the bevelling-board; and so proceed with every floor alternately to O, as at *b, fig. 8*; thus the bevellings may be taken for every floor at each diagonal, and be thence marked on the board, as *Plate VII. fig. 8*.

In the next place provide bevelling-boards, one for each futtock, and one for the top-timbers, observing that the breadth of each board corresponds with the siding of its respective futtock and top-timber; then, to take the bevellings for each, we must act as before explained for the floors; only observing which futtocks are standing bevellings, and which are under: for futtocks that have standing bevellings, the siding of the timber must be set off upon each diagonal, abaft the joint of its respective timber in the fore-body half-breadth plan, and before the joint in the after-body, and so contrarywise for those which are under-bevellings.

Therefore observe, that floors have under-bevellings, lower or first futtocks standing bevellings, second futtocks under, third futtocks standing, fourth futtocks under, and top-timbers standing bevellings. The bevellings of each may now be taken at every diagonal for every timber, and marked on their respective boards, the fore-body on one side, and the after-body on the other.
